with when the two apices are compared—differences that first received a satisfactory explanation a few years ago at the hands of Fetterolf and Landis. In the account of hydrothorax (p. 191) no mention is made of the importance of the liver in determining the great frequency with which such effusions appear on the right side, a matter emphasized by Vaquez in 1913. The sternal angle of Louis, correctly named on p. 180, is called the angle of Ludwig on p. 200, with no note to explain that Ludwig is the German form of the name Ludovicus, which is in turn the Latin form of the French name Louis, and that the two angles are the same. From the medical point of view the book would gain if some transverse sections across the thorax were added to the excellent diagrams of frozen sections placed at the end of the volume; they would be most helpful to students seeking to understand the semeiology of diseases of the heart, lungs, aorta, and oesophagus. The book is clearly written, and contains numerous important references to the medical and anatomical literature. It contains a great deal of useful information; the only fault the medical student will find with it will lie, no doubt, in its length.

In the third edition Professor HILDEBRAND brings up to date his *Grundriss der Chirurgisch-Topographischen Anatomie*,³ published first in 1893. The feature which gives the book a special value for English readers is the attention paid to *Leitungsanästhesie*. The new subject matter is particularly concerned with the questions of cranio-cerebral topography, the distribution of lymph vessels with special reference to the extension of malignant growths, and the position of the sensory nerves from the point of view of choosing the site of injection in producing local anaesthesia. The anatomy of the various regions of the body which are of special interest to the surgeon is first described, and at the end of each section a reference is made to the part which the anatomy of the region plays in surgery. To this is added an account of the region as it can be made out from an examination of the living subject, and finally the positions of the sensory nerves are described. It is somewhat surprising that in a book of this character and scope no mention should be made of the various sensory segmental areas, and that the work of Head and other British neurologists should be entirely ignored.

The third edition of Professor BUCHANAN'S *Manual of Anatomy*⁴ contains a sound and short account (so far as any textbook of anatomy can be short) of systematic and practical anatomy and embryology. The second impression of this work was reviewed in the *BRITISH MEDICAL JOURNAL* of September 26th, 1914; it is sufficient to add to that review (which gave a very favourable account of Professor Buchanan's *Manual*) a note to the effect that the latest edition contains a new chapter on general embryology, and, in addition, a number of new illustrations. The old anatomical nomenclature is retained in despite of the Bâle synonyms, many of which are given in an appendix. This is a feature that should continue to commend the volume to medical students—a conservative class.

In Part I of *Die Anatomie des Menschen*⁵ the author, Professor FRIEDRICH MERKEL, deals with the subjects of anatomical structure and general embryology. The fact that he completes his account of these subjects within 248 pages and that he includes no fewer than 251 illustrations in the text gives some idea of the scope of the book. The work is a textbook designed to supply the medical student with a succinct and clear account of the subjects which will form the groundwork for all his later studies. The special problems with which authors of such textbooks are confronted are those of selection and compression, for, owing to the rapid advance in knowledge of the various subjects of the medical curriculum,

¹ *The Ductless Glandular Diseases*. By W. Falta, Vienna. Translated and edited by M. C. Meyers, M.D.; with a foreword by A. E. Garrod, M.D. Oxon., F.R.C.P. Lond., F.R.S. Philadelphia and London: P. Blakiston's Son and Co. 1915. (Roy. 8vo, pp. 692; 101 figures. 7.00 dols.)

⁴ *Manual of Anatomy, Systematic and Practical, including Embryology*. By A. M. Buchanan, M.A., M.D., C.M., F.R.F.P.S. Glas. Third edition. University series. London: Baillière, Tindall and Cox. 1915. (Demy 8vo, pp. 1743; 675 figures. 21s. net.)

⁵ *Die Anatomie des Menschen*. Von Professor Dr. F. Merkel. Part I. Allgemeine Gewebelehre Grundzüge der Entwicklungslehre. Wiesbaden: J. F. Bergmann. Glasgow: F. Bauernmeister. 1913. (Imp. 8vo, pp. 263; 251 figures. 8s.)

it is desirable to confine within certain limits the anatomical studies of the student. Professor Merkel has, we think, succeeded in the task which he set himself, thanks, no doubt, largely to the important *German Handbooks and Atlases* upon which he has been able to draw for his text and illustrations. An omission, which we are at a loss to understand, is that in the section dealing with the structure of the body, and which includes, by the way, an account of the blood and even of haemin crystals, there is no mention of the structure of a tooth. The book may be useful to teachers in this country faced with the same problems—namely, what to teach and what to omit.

The Intervertebral Foramina in Man,⁶ by HAROLD SWANBERG, is, as its author states, a supplement to *The Intervertebral Foramen*, which was reviewed in these columns some time ago. The earlier book dealt with the structure and contents of the foramen in the cat, and therefore had not the interest or practical value of the present work. The description of the foramen is based on an examination by microscopical sections of the foramen between the seventh and eighth thoracic vertebrae in a male child aged 5 months. The specimen was decalcified and forty-nine serial sections were made in the sagittal plane. Photomicrographs of four of these are reproduced. The main features agree with those already observed in the cat. The chief points made are that the size of the foramina does not correspond with the size of the nerves; that while in the median part of the foramen there is a large amount of fat, in the lateral part the fat is replaced by fibrous tissue, and that among the contents of the foramina is a number of lymphatic nodes. The book is the outcome of a careful piece of work patiently and skilfully carried out, but the contribution to our knowledge is on the whole rather insignificant. This, however, is in no way due to the author, but rather to the subject.

The pamphlet entitled *Anatomie der Bauchspeicheldrüse*,⁷ contains the account of the pancreas contributed by Dr. SOBOTTA to von Bardeleben's handbook on human anatomy. It contains a brief historical review, in which the growth of knowledge regarding the gland is traced from the date of Hippocrates to the time of the memorable discovery of the duct by Wirsung in 1642, and still later to that of the even more important discovery of the islands and centro-acinar cells made by Langerhans in 1869. There follows an account of the comparative anatomy and embryology, a description of the macroscopical and microscopical appearances of the gland and its ducts, with their topographical relations; and, finally, an account of the arrangement of its blood vessels and lymph vessels and of its nerves. A bibliography giving the titles of no fewer than 386 papers supplies the reader with the literature on the subject down to September, 1913. The volume is adequately illustrated.

THE CAECUM AND INTESTINAL TOXAEMIA.

METCHNIKOFF's doctrine that the colon is a useless if not harmful prolongation of the alimentary canal finds a vigorous opponent in Dr. JOHN FLYNN of Sydney, who has written essays on the *Morphology and Physiology of the Caecum*.⁸ He discusses first the comparative anatomy of certain Australian animals, pointing out that in the carnivorous dasyure or native cat the caecum is entirely absent and there is little or no distinction between the large and small intestines, whereas in the mixed feeding bandicoot there is a fairly well marked difference, the caecum being of medium size and simple; in the koala or native bear, a purely vegetable feeder, it is long and complicated. He holds that this indicates that the caecum supplements the functions of the stomach in the digestion of certain kinds of food. He strengthens this anatomical argument by quoting the researches of Keith on starch digestion, which showed that in

the lower part of the ileum no starch reaction was obtained, but it reappeared in the middle of the transverse colon, in consequence, Keith suggests, of the cellulose envelopes, which were too strong for the enzyme action of the upper portion of the alimentary canal, having yielded to the special digestion of the caecum. Dr. Flynn also quotes Keith's researches on the mechanism of the ileo-caecal valve, which tends to show that it controls the passage of the contents of the ileum into the caecum, and permits it only when intestinal digestion and absorption have been completed. The valve sphincter is governed by reflexes which start from the mucous lining of the caecum, but are abolished when an artificial opening is made in the caecum, so that diarrhoea ensues. Caecal digestion, it is suggested, is due to bacterial action. It is argued that the only agents which could produce intestinal toxæmia are the products of enzyme digestion or of bacterial digestion or exotoxins derived from intestinal bacteria. He contends that the toxic proteoses, in passing through the walls of the intestine, are hydrolyzed and rendered harmless, and that carbohydrate and fat derivatives are not capable of producing toxic symptoms. If the symptoms are due to the intestinal bacteria themselves it must, he argues, be through exotoxins, the products of their action upon the medium, or endotoxins formed within them and set free by their disintegration. Strasburger's estimate of the enormous numbers of dead bacteria in faeces points to their destruction in the bowel. As it is the function of the liver to render innocuous any poisons formed in the intestine, if toxæmia occurs it must be due to hepatic failure. He holds that not only is the nature of intestinal toxæmia vague, but also the mechanical factor upon which it is supposed to depend. He believes the relaxation of the abdominal muscles to be of far greater importance in producing constipation than such conditions as abnormal mobility of the caecum, kinking at the hepatic and splenic flexures, adhesions around the ascending colon, and abnormal mesenteries. While acknowledging the work of Sir Arbuthnot Lane, and the lasting and material benefit that may follow the removal of a permanently diseased colon, he protests against the doctrine that a man who has no colon is in a better state than one who possesses a healthy bowel, and "if Lane by a sort of intuition of genius can give a new lease of life to certain chronic invalids," his teaching "should not be applied on any occasion and on every frivolous pretext to all conditions of men and women in whom this vague condition of intestinal toxæmia may be supposed to reside."

VICHY.

THE bulky volume on the arthritic diathesis, by Drs. E. GAUTRELET and H. DE LALAUBIE, two of the editors of the *Revue des maladies de la nutrition*,⁹ is the outcome of the collaboration of one of the oldest practitioners at Vichy with the head of the local laboratory for biological chemistry. They describe it as an attempt to co-ordinate the numerous papers published from time to time on the cure at Vichy, and to explain the doctrines developed by time and experience, and by which those who practise there are guided in their administration of the waters. These doctrines differ in certain respects from those usually taught in the schools of medicine, but it is desirable that those who send their patients for treatment at this great French watering-place should be aware of the principles which guide the practice of the physicians to whom their patients are entrusted. The authors regard arthritism as depending upon hyperacidity and having a histological basis in the thickening of the cellular septa which interferes with, and more or less arrests, the osmotic exchanges essential to life. About a quarter of the book is occupied by a retrospect of the ancient and modern theories of gout and allied diseases, and about half is devoted to a description of the clinical conditions more or less closely related to the gouty diathesis; the concluding portion of the book deals with the waters of Vichy and their method of employment, internal and external, and all the various adjuncts of treatment employed there. As there are few regions of the body unaffected by the

disturbances of nutrition which may be classed as gouty it may easily be understood that the subject is large enough to excuse a big book. All the more to be regretted is it that there is no index and only a meagre table of contents.

NOTES ON BOOKS.

WE have read with much interest the philosophical poem whose existence its author, the late Dr. B. G. MORISON,¹ revealed to his wife only the day before he died. It takes the form of a dialogue between man and the spirit of life, and inculcates a serene and lofty confidence that, in despite of all transient and seeming triumphs of wrong, suffering, and death, all is or shall be well. Life is, for "the greatest and the least" alike, in essence indestructible, and though "savage ruthless force and subtle ill" may find "allotted meed" and pursue awhile "a favoured hurtful course," yet

The hour approaches when, to newer need
Unequal found, their baneful sway shall cease;
E'en now does victim Right, striving succeed,
And win from their undoing its release.

In addition to the title poem, some alternative stanzas, and a couple of short lyrics, the volume contains an interesting introductory note, "The Physician as Poet," a "Mémorial," and two portraits, thus completing its claim to rank as a worthy memorial of an attractive and gifted personality. (An obituary notice of Dr. Morison appeared in the JOURNAL of February 6th, 1915, page 274.)

Dr. W. H. B. STODDART'S Morison Lectures on *The New Psychiatry*, delivered at the Royal College of Physicians of Edinburgh in March, 1915, have already been noted in detail in the BRITISH MEDICAL JOURNAL. They have now been republished in book form.² They form a brief introduction to the principles and practice of psycho-analysis.

Dr. STEVENS'S manual of medicine,³ now in its tenth edition, was first published in 1892. It is a book prepared especially for students, and is redolent of suggestions of the midnight oil rather than of the bedside. In other words it is a comprehensive and workman-like textbook for the examinee, brief and clearly written, stripped of superfluous matter, uninteresting to the practitioner of medicine for the reasons that commend it to the medical student. Considerable alterations and additions have been made in the present edition to bring it up to date. So well-established an elementary textbook of medicine as this can stand on its merits, and is not in need of further commendation.

Under the title of *The Infant: Nutrition and Management*,⁴ Dr. ERIC PRITCHARD publishes a collection of papers on various points connected with infant welfare. The book is brought out at a happy time, since much attention is drawn just now to the need of preserving infant life. Dr. Pritchard's hints with regard to the early management of lactation are full of sound common sense, as, indeed, is his advice on the regularity and daily management of the child's functions. We heartily agree with Dr. Pritchard when he insists on natural processes being allowed fair play, and with him we deprecate the early administration of castor oil or artificial feeding in the first forty-eight hours of existence as usurping and unwarrantably interfering with the effects colostrum on the one hand and meconium on the other are designed to have. Dr. Pritchard is inclined to think that many bottle-fed babies are apt to be overfed rather than underfed. It is suggested that the numerous garments the babies of poor parents usually wear are responsible to some extent for the underfeeding of some infants. The child who is overburdened with clothes cannot be vigorous in its movements nor the action of its skin healthy, and its appetite is therefore poor.

Dr. D. M. MACDONALD'S small volume on *Practical Prescribing and Treatment in the Diseases of Infants and*

*Children*⁵ consists of short and concise paragraphs arranged in dictionary form. We only fear lest a book such as this may tend to make some busy young practitioners trust to obtaining knowledge in too concentrated a form. We are glad to see that regularity in the daily habits of children is insisted on and that medicines for constipation, though various good formulae are given, are deprecated. The notes on diseases of the eye and the tuberculous child are practical, and the alterations in the recent edition of the *British Pharmacopoeia* are clearly presented in the last chapter.

An interesting record of the research work carried out during 1914 at the Research Laboratory of Parke, Davis and Co. at Detroit is furnished by the republication, in book form,⁶ of more than twenty papers by various authors. These papers originally appeared for the most part in different American journals. They deal mainly with bacteriological subjects; a few are concerned with pharmacy. The volume contains evidence of much useful work, and does the greatest credit to the long-sighted wisdom of the firm that has paid for the expenses of the researches and of their publication in so readily accessible a form.

⁵ *Practical Prescribing and Treatment in the Diseases of Infants and Children*. By D. M. Macdonald, M.D., F.R.C.P.E. Oxford Medical Publications. London: H. Frowde, and Hodder and Stoughton. 1915. (Pott 8vo, pp. 199. 5s. net.)

⁶ *Collected Papers from the Research Laboratory of Parke, Davis and Co., Detroit, Michigan*. Reprints—Vol. 3, 1915. Director, Dr. E. M. Houghton. (Med. 8vo, pp. 345.)

THE NOTIFICATION OF MEASLES.

THE Order with regard to the "notification and treatment of measles and German measles," which came into force on January 1st, 1916, imposes a somewhat different duty as regards notification from that imposed by the Infectious Disease Notification Act, 1889. That Act provides as follows:

Where an inmate of any building used for human habitation . . . is suffering from any infectious disease to which the Act applies then, unless such building is a hospital in which persons suffering from an infectious disease are received . . . the head of the family to which such inmate belongs, and in his default the nearest relatives of the patient present in the building or in attendance on the patient, and in default of such relatives every person in charge of or in attendance on the patient, and in default of any such person the occupier of the building shall, as soon as he becomes aware that the patient is suffering from an infectious disease to which the Act applies, send notice thereof to the medical officer of health of the district.

Every medical practitioner attending on or called in to visit the patient shall, on becoming aware that the patient is suffering from an infectious disease to which the Act applies, send to the medical officer of health for the district a certificate. . . .

Under the provisions of the Infectious Disease (Notification) Act, therefore, two notifications, the one from the person responsible for the care of the patient and the other from the attendant doctor, are receivable by the medical officer of health, and the Act provides that the local authority shall pay to

every medical practitioner for each certificate duly sent by him in accordance with the Act a fee of 2s. 6d. if the case occur in his private practice, and of 1s. if it occurs in his practice as medical officer of any public body or institution.

It would, perhaps, be too much to say that the provision in the Act with regard to notification by the head of the family is a dead letter, but we believe we are correct in stating that in practice the authorities very seldom take steps to enforce it.

If now we compare the provisions of the Notification Act (1889) and of the General Order of December 13th, 1910, on the one hand, with the regulations as to measles and German measles, we find the position somewhat different.

The measles regulations provide as follows:

(Article V.) Every parent or guardian or other person, as soon as he becomes aware of, or has reasonable grounds for supposing that any person in his charge is suffering from measles or German measles, shall, unless the case has already been notified by a medical practitioner, forthwith notify the case to the medical officer of health for the district.

(Article VI.) Every medical practitioner, as soon as he becomes aware that any person upon whom he is in professional attendance is suffering from measles or German measles, shall forthwith make and sign a notification . . . and shall transmit the notification to the medical officer of health for the district.

² *The New Psychiatry*. By W. H. B. Stoddart, M.D., F.R.C.P. London: Baillière, Tindall, and Cox. 1915. (Demy 8vo, pp. 70. 3s. 6d. net.)

³ *Manual of the Practice of Medicine, prepared especially for Students*. By A. A. Stevens, A.M., M.D. Tenth edition. Philadelphia and London: W. B. Saunders Co. 1915. (Cr. 8vo, pp. 629. 12s. 6d. net.)

⁴ *The Infant: Nutrition and Management*. By E. Pritchard, M.A., M.D., Oxon., M.R.C.P. London: E. Arnold. 1914. (Crown 8vo, pp. 271. 3s. 6d. net.)

Provided that a medical practitioner shall not be required to notify a case of measles or German measles . . . and shall not be paid a fee for so doing

(a) If he has reasonable grounds for supposing that the case has already been notified under these regulations;

(b) If the case is notifiable or has been notified by a medical practitioner under the Infectious Disease (Notification) Act, 1889, Section 55 of the Public Health (London) Act, 1891, or under the provisions of any local Act or order made thereunder;

(c) If a case of the disease which he is attending, whether measles or German measles, has to his knowledge occurred in the same household or institution, and been notified within the period of two months immediately preceding the date on which he first becomes aware of the disease in the case he is attending; or

(d) If the case is being treated in a hospital for infectious diseases.

Article VIII provides for the payment of fees to the medical practitioner notifying a case under the regulations—2s. 6d. in respect of a private practice case, and 1s. if the case occurs in the practitioner's practice as medical officer of any public body or institution.

It will therefore be seen, on comparing the respective provisions of the Infectious Disease (Notification) Act and Measles Regulations which we have quoted, that whilst the Act imposes upon every medical practitioner in attendance upon a case, say, of scarlet fever, the duty of notifying the medical officer of health whether the case has already been notified or not, the measles regulations do not require a medical practitioner attending a case of measles to notify the medical officer of health "if he has reasonable grounds for supposing that the case has already been notified." The Local Government Board has stated that it is advised that if more than one medical practitioner is attending on or called in to visit a patient suffering from, say, scarlet fever, each practitioner is bound, under the Infectious Disease (Notification) Act, to send a certificate, and is entitled to the prescribed fee of 2s. 6d. or 1s., as the case may be, for such notification. On the other hand, a doctor called in to attend a case of measles upon which another doctor has previously been in attendance would be under no duty to notify if he had reasonable grounds for supposing that the case had already been notified; and, indeed, there being no duty upon him to notify the case, it would seem that if he nevertheless notified the medical officer he would be entitled to no fee for such notification, and the same result follows if a doctor has reasonable grounds for supposing that a case has already been notified by the patient's parent or guardian.

The position is perhaps best understood by taking a concrete case. Suppose, for instance, a woman writes to the M.O.H. that she suspects that her child is suffering from measles, and that the M.O.H. visits the house and finds that the child is suffering from measles, and in that way receives a notification of the case. Later, the woman calls in a medical man, but says nothing to him about the visit of the M.O.H.; he diagnoses the case and notifies the M.O.H. accordingly. The doctor's position is clear. He had no reasonable grounds for supposing that the case had already been notified and was therefore under a duty to notify. He is entitled to receive his fee. Even though the M.O.H. was himself also engaged in private practice, he would not appear to be entitled to any fee because the duty he performed was incidental to his appointment as M.O.H. and not otherwise.

Again, a doctor is called in to a case of measles; there is something which should show that another doctor has been previously in attendance on the case; that would, unless he were told that the doctor previously in attendance had not in fact notified the case, no doubt be held to relieve him of the duty of notifying, and, if he did notify, would disentitle him from receiving a fee.

In reading the two illustrations we have given it should be borne in mind that "notification" means "notification after diagnosis," and therefore a mere statement of suspicion is not a notification.

This distinction between the notification under the Act and that under the measles regulations is, no doubt, designedly made with a view to economy, but we cannot help feeling that it is one which may very well defeat the whole purpose of the regulations, which were made in order to enable the authorities to obtain control over two infectious diseases which were not previously notifiable.

THE DUTIES OF MEDICAL PRACTITIONERS IN CASES OF CRIMINAL ABORTION.

THE question as to how far a medical man, who obtains in his professional capacity knowledge of the commission of a criminal offence, is under a duty as a citizen to give information to the police authorities and so set the criminal law in motion, is one which has great interest for the medical profession.

It is manifest that as a standing rule applicable to the vast majority of cases it is of the very highest importance that professional confidence should be respected and held inviolate. Probably the case of most frequent occurrence is that of the medical man called in to attend upon a woman upon whom he comes to the conclusion an illegal operation has been performed, and in this case, at any rate, it is now safe to say that the doctor is under no obligation to, and indeed should not, divulge the information which he has obtained in his professional capacity.

In order to explain how the point has now arisen we must go back to 1896, when the late Lord Brampton (better known as Mr. Justice Hawkins), in charging a grand jury, said:

I doubt very much whether a doctor called in to assist a woman, not in procuring an abortion, for that in itself is a crime, but for the purpose of attending her and giving her medical advice, could be justified in reporting the facts to the Public Prosecutor. Such action would be a monstrous cruelty. . . . There might be cases when it is the obvious duty of a medical man to speak out, and it would be a monstrous thing for a medical man to screen a person going to him with a wound which it might be supposed had been inflicted in the course of a deadly struggle.

Lord Brampton's remarks were brought to the notice of the Royal College of Physicians of London, and in the result it obtained the joint legal opinion of Sir Edward Clarke and Mr. Horace Avory; the latter was then in practice at the junior Bar, but has since been raised to the Bench. They advised that a medical practitioner was not liable to be indicted for misprision of felony (an offence which is practically obsolete) merely because he does not give information in a case where he suspects that criminal abortion has been practised. There the matter rested until the close of 1914, when at the Birmingham Assizes in December Mr. Justice Avory had to deal with a case of an alleged illegal operation upon a woman on whom three successive doctors had been in attendance. None of these doctors had given information to the police, and, in consequence, there was no evidence upon which a jury could convict the prisoner who was charged with having performed the illegal operation. In charging the grand jury, the judge made the following observations:

Under circumstances like those in the present case, I cannot doubt that it is the duty of the medical man to communicate with the police or with the authorities in order that one or other of those steps may be taken for the purpose of assisting in the administration of justice. No one would wish to see disturbed the confidential relation which exists, and which must exist between the medical man and his patient, in order that the medical man may properly discharge his duty towards his patient, but there are cases, and it appears to me that this is one, where the desire to preserve that confidence must be subordinated to the duty which is cast upon every good citizen to assist in the investigation of a serious crime such as is here imputed to this woman. In consequence of no information having been given, it appears to me that there is no evidence whatever upon which this woman can properly be put upon her trial.

I have been moved to make these observations because it has been brought to my notice that an opinion to which I was a party some twenty years ago, when I was at the Bar, has been either misunderstood or misrepresented in a textbook of medical ethics, and I am anxious to remove any such misunderstanding if it exists. It may be the moral duty of the medical man, even in cases where the patient is not dying, or not likely to recover, to communicate with the authorities when he sees good reason to believe that a criminal offence has been committed. However that may be, I cannot doubt that in such a case as the present, where the woman is, in the opinion of the medical man, likely to die, and, therefore, her evidence likely to be lost, that it is his duty; and some one of these gentlemen ought to have done it in this case.

Mr. Justice Avory was therefore insisting that, professional secrecy notwithstanding, medical men are under the same moral duty as other citizens of the State in all cases in which they become aware of the commission of a criminal offence, to give information to the authorities.

In this, as we have seen, he differed from the late Lord Brampton.

These remarks were brought to the attention of the Council of the British Medical Association, and, after full consideration of the matter in consultation with the solicitor to the Association, a deputation was appointed to confer with the Lord Chief Justice on the question raised. This deputation was received by the Lord Chief Justice on May 3rd, 1915, and the Attorney-General and Public Prosecutor were also present. It was then ascertained:

(a) That it is desired by the authorities that information should be given to them by medical men in attendance upon a woman suffering from the effects of abortion brought about by artificial intervention.

(b) That the circumstances under which it was desired that this communication should be made were the subject of the following three limitations:

(1) That the medical man was of opinion either from his examination of the patient and/or from some communication that she may have made to him that abortion had been attempted or had been procured by artificial intervention.

(2) That he was of opinion either from his observations of and/or from a communication made to him by his patient that such artificial intervention had been attempted by some third party other than the patient herself, and

(3) That the medical man was of opinion that his patient, due to such artificial intervention, was likely to die, and that there was no hope of her ultimate recovery.

Upon this the Council made the following observations in its report to the Annual Representative Meeting, 1915:

The Council understands that whereas Solicitors and Barristers have an absolute privilege of protection in regard to statements made to them in their professional capacity involving matters of criminal import or otherwise, no other class of persons is accorded such legal protection by State authority or Act of Parliament, although in the case of ministers of religion such protection is universally observed and recognized by custom in the Courts.

There is, however, no such universally recognized protection attaching to medical men in respect of statements made to them by a patient; in fact there is a considerable conflict of authority upon the subject.

The Council is advised that no obligation rests upon a medical practitioner to disclose the confidences of his patient without the patient's consent, and suggests that if the State desires to set up such an obligation it should at the very least preface such an endeavour by affording to the practitioner protection from any legal consequences that may result from his action. Without any desire to claim the right to refuse to make such disclosures in obedience to the order of a Court of Justice, the Council, after hearing the report of the Deputation received by the Lord Chief Justice on May 3rd, 1915, has decided to adhere to the following Resolutions which it passed on January 27th, 1915:

That the Council is of opinion that a medical practitioner should not under any circumstances disclose voluntarily, without the patient's consent, information which he has obtained from that patient in the exercise of his professional duties.

That the Council is advised that the State has no right to claim that an obligation rests upon a medical practitioner to disclose voluntarily information which he has obtained in the exercise of his professional duties.

The matter has also been taken up by the Royal College of Physicians of London. The College passed certain resolutions last July. It was subsequently considered advisable to obtain an opinion from Mr. E. D. Muir on the legal advice appended to the resolutions, which were finally adopted in the following form after they had been submitted to the Public Prosecutor for his approval. The resolutions of the College and the advice it has received are in the following terms:

Resolutions concerning the Duties of Medical Practitioners in Relation to Cases of Criminal Abortion, adopted by the Royal College of Physicians of London on January 27th, 1916.

The College is of opinion—

1. That a moral obligation rests upon every medical practitioner to respect the confidence of his patient; and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her.

2. That every medical practitioner who is convinced that criminal abortion has been practised on his patient

should urge her, especially when she is likely to die, to make a statement which may be taken as evidence against the person who has performed the operation, provided always that her chances of recovery are not thereby prejudiced.

3. That in the event of her refusal to make such a statement, he is under no legal obligation (so the College is advised) to take further action, but he should continue to attend the patient to the best of his ability.

4. That before taking any action which may lead to legal proceedings, a medical practitioner will be wise to obtain the best medical and legal advice available, both to ensure that the patient's statement may have value as legal evidence, and to safeguard his own interests, since in the present state of the law there is no certainty that he will be protected against subsequent litigation.

5. That if the patient should die, he should refuse to give a certificate of the cause of death, and should communicate with the coroner.

The College has been advised to the following effect:

1. That the medical practitioner is under no legal obligation either to urge the patient to make a statement, or, if she refuses to do so, to take any further action.

2. That when a patient who is dangerously ill consents to give evidence, her statement may be taken in one of the following ways:

(a) A magistrate may visit her to receive her deposition on oath or affirmation. Even if criminal proceedings have not already been instituted, her deposition will be admissible in evidence in the event of her death, provided that reasonable written notice of the intention to take her statement was served on the accused person, and he or his legal adviser had full opportunity of cross-examining.

(b) If the patient has an unqualified belief that she will shortly die, and only in these circumstances, her dying declaration will be admissible. Such a declaration may be made to the medical practitioner, or to any other person. It need not be in writing, and if reduced into writing it need not be signed by the patient nor witnessed by any other person, though it is desirable that both should be done, or that, if the patient is unable to sign, she should make her mark. If possible, the declaration should be in the actual words of the patient, and if questions are put, the questions and answers should both be given, but this is not essential. If the declaration cannot there and then be reduced into writing, it is desirable that the person to whom it is made should make a complete note of it as soon as possible.

The position may therefore be summarized shortly:

1. Any one who, knowing of the commission of a criminal offence, attempts to conceal his knowledge from the authorities may himself be guilty of the offence of misprision of felony—an offence, however, which is practically obsolete.
2. An ordinary citizen, not being a barrister or solicitor, is under a moral duty to inform the authorities when he has knowledge of the commission of a criminal offence.
3. A medical man, however, is under no such moral duty where his knowledge is obtained in his professional capacity, so far, at any rate, as the offence of abortion is concerned.

THE United States Census Bureau estimates that the death-rate for 1914 in the registration areas of the country was 13.6 per 1,000, being the lowest rate recorded. The returns cover about 67 per cent. of the population, and are considered trustworthy. The death-rate of New York City had fallen 25.8 per cent., that of San Francisco 23.6 per cent., and that of other large cities showed a considerable lowering of mortality.

THE annual report of the Glasgow Eye Infirmary states that the directors have been confronted with two difficulties—the increase in the cost of supplies and the depletion of the medical staff. In addition to the general increase in the price of food, there has been difficulty in respect of drugs. The drugs indispensable in ophthalmic surgery, the report states, are mostly of foreign origin, and are now only obtainable at greatly enhanced prices, which range from five to twenty times the prices existing before the war. The charges under this heading would have been considerably heavier but for the fact that drugs are not now supplied by the infirmary to patients insured under the National Health Insurance Act.

British Medical Journal.

SATURDAY, FEBRUARY 5TH, 1916.

MEDICAL RECRUITING.

At a time like this the main interest of the work of the Association must be centred in the endeavour of the profession to further the national interests in the war. It is therefore not to be wondered that the report of the Central Medical War Committee claimed much attention from the meeting of the Council of the British Medical Association on January 26th. That the report of the Committee was adopted without amendment, save such verbal alterations as were proposed by the Chairman of the Committee himself, after it had run the gauntlet of the searching criticism of the members of the Council, speaks well for its work. The Committee, it will be remembered, was appointed at the instance of the Annual Representative Meeting last July. The representatives of the British Medical Association were the four *ex officio* members (the President, the Chairman of Representative Meetings, the Chairman of Council, and the Treasurer), four other members elected by the Council, four members elected by the Representative Meeting from among its own body, and four other persons also chosen by the Representative Body—namely, Sir William Osler, Sir T. Clifford Allbutt, the Master of Christ's College, Cambridge, and Dr. T. Jenner Verrall. The Committee had power to co-opt six other members representative of universities, colleges, and other medical bodies, and under this power has chosen the President of the Royal College of Physicians, London; the Past-President of the Royal College of Surgeons, London; the Dean of St. Bartholomew's Medical School, the Secretary of the London Panel Committee, the Dean of the Faculty of Edinburgh University, who is also a member of the Scottish Medical Emergency Committee; and the Irish Medical Secretary of the Association, who is also the Secretary of the Irish Medical War Committee. Representatives of the Insurance Commissioners and of the Local Government Board attend the meetings without vote. The Committee has met eleven times and the Executive Subcommittee twenty-three times. Government departments have been interviewed—some of them many times, and the roll shows that the members have been most assiduous in their attendance.

The status of the Committee, which met first on July 30th, had gradually been strengthened; and, as will have been gathered from Mr. Tennant's statements in the House of Commons on January 12th and 20th,¹ it may now be said to be an advisory committee to the Director-General on matters which affect the relation between the medical demands of the army and the medical requirements of the civil population, and to act also as an active recruiting agency to secure medical officers for the R.A.M.C.

Lord Derby definitely turned over the recruiting of doctors in England and Wales to the Central Medical War Committee, and in Scotland to the Scottish Medical Emergency Committee; the Army Council subsequently announced that no qualified medical practitioner willing to accept, if offered, a commission

in the Royal Army Medical Corps should be accepted as an ordinary combatant, and that the certificate of enrolment issued by the committees would be accepted as conclusive evidence on this head by all recruiting officers. Medical practitioners so enrolled, the Army Council stated, "will not be posted to a combatant unit, and will await the instructions" of the Central Medical War Committee, or the Scottish Medical Emergency War Committee, as the case may be. The Committee, acting in conjunction with the Scottish Committee, set itself to secure a large number of additional medical officers by the middle of January, and though the full tale was not attained, the Director-General stated that "on the whole he was not dissatisfied with the result." The duty of the Committee is not only to secure new medical officers for the new armies, but also new men to take the place of those who have been invalided, or who— their number is not, we believe, at present large—having served one year, for divers reasons have to return to civil life. The effort must be continued, for the demand cannot be expected to diminish. The Central Medical War Committee commended in the warmest terms the work of the local Medical War Committees. It was able to report that out of 172 areas in England and Wales all have committees working save four (West Bromwich, Dover, Lewisham, and Lewes and East Grinstead). The report stated that it was impossible to speak too highly of the arduous work and self-sacrifice devoted to the organization and conduct of many of these committees, and the Central Committee especially thanked those who, by acting as chairmen and honorary secretaries, had enabled it to establish a network of committees which have carried on the recruiting work for officers for the R.A.M.C., and have enabled some thousands of medical men to join the services, knowing that their interests during their absence will, so far as possible, be protected.

The work of the local committees is growing in importance: they must act as recruiting agencies; they must know all the men of military age, their position, the possibility of sparing them from civil work, how to safeguard their practices, and in particular must promptly advise the Central Committee whether or not a certain commission applied for may or may not be granted. Recently the Director-General has promised to put all the local committees in touch with the Deputy Director in each home command, so that changes in mobilization may be known and arranged for.

The Committee presses for the immediate enrolment of every medical man of military age—that is, of 45 years and under. Every man should enrol, irrespective of whether he thinks he can or should go or not. He is asked to put his case before the Committee for consideration and decision. Only by a complete enrolment can the Committee know the general position and do justice as between man and man and district and district. Not every enrolled man will be called upon to go, and no man will be called upon without consultation with his local committee.

Much good work has been done by local committees. Some districts have been particularly difficult to deal with; this applies to London, for instance, where the population is of a floating character and patients are not attached by close ties to their doctors, as they are in country districts. The problem still calls for much attention, and as the difficulty of getting men increases it may be necessary to consider some scheme for redistribution of practitioners.

¹ BRITISH MEDICAL JOURNAL, January 22nd, p. 140, and January 29th, p. 178.

The Committee had called the attention of the President of the General Medical Council to some few instances in which men had taken advantage of the absence of their colleagues. The President intimated in his address at the November session that the Council would take a very serious view of any case brought before it in which such unpatriotic and unprofessional conduct was proved. The Committee had also, through the lay press, appealed to the public to consider the interests of their usual doctor when he is away on service, and to tell whomsoever they may go to the name of the absentee doctor who was their usual attendant.

A letter had been sent to the medical committees of all civil hospitals asking them to consider the minimum requirement for carrying on the hospitals during the war, and information had been given as to measures taken by various hospitals in coping with shortage of junior residents.

Much tribulation had come to the Committee owing to grievances felt with regard to certain War Office regulations on points of age and physical fitness for commissions for men on home service. At the outset of the Committee's work recruiting was hindered owing to the many men of military age and fit for general service—that is to say, either at home or abroad—holding commissions and being employed on home service only. The Committee desired the Director-General to instruct "D.D.M.S.'s and A.D.M.S.'s not to retain or accept for work in military hospitals at home medical practitioners of military age who were physically fit, but to encourage such practitioners to accept commissions in the R.A.M.C."; the same was to apply to Red Cross and Voluntary Aid Detachment hospitals. The Director-General notified that "no man under 45 years of age will be employed unless he undertakes general service obligation for a year, and is found to be physically fit for duty at home and abroad." It will be noted that the army order differs from the request of the Committee. It excludes not only fit men under 45 from home service but also unfit men. The Committee therefore again approached the War Office on the matter, for it was felt that hardship would be done to men who would have to surrender their commissions under the order, and that men useful for home work would be refused commissions. The War Office replied that the decision was come to on departmental grounds. Commissions, it was pointed out, carried obligations to both sides, and the Treasury would not entertain these obligations towards men known to suffer physical disability. It was, on the other hand, stated that these men would be taken on for home service as civil medical practitioners. The matter was discussed at the meeting of the Council at some length, but a motion directing the Committee to seek a further interview with the Director-General thereon was lost.

The need for the economical use of medical officers has been a constant source of comment: it was dealt with in a lengthy section of the report, and it was debated in earnest by the Council. The Committee has had many interviews on the subject with the Director-General, and reported that while it believed that individual instances of wastage may be proved, it has been convinced by its communications with the Director-General that on the whole these complaints are due to ignorance of the larger questions of army medical administration. Reserves must be maintained; men who may seem to be idle are nevertheless indispensable. The present siege warfare makes many men in all branches of the army apparently idle and useless, but they must be there on the spot,

for who knows when the siege may give place to field operations? "The Committee feels that, after all, the responsibility must rest upon the military authorities, who would be blamed if at any given time it were found that there were not sufficient medical officers, and the Committee does not consider that it is wise or patriotic to question the decision of the military authorities, arrived at, as the Committee has good reason to know, after full consideration of the criticisms that have been offered."

SCIENCE, EDUCATION, AND GOVERNMENT.

A VOLUNTARY committee of men of science has issued a memorandum which is a serious indictment of the attitude of public opinion, but especially of political opinion in this country, towards the study of science and its application to practical affairs, including military administration. It would, perhaps, be more correctly described as an appeal to the public and an indictment of politicians, although it points out that the ignorance of science displayed by the highest ministers of the state, by almost all public departments of the civil service, and almost universally in the House of Commons, is shared by the general public, including a large proportion of those engaged in industrial and commercial enterprise. Important exceptions to the rule are recognized in the navy and the medical service of the army. "In both these services," the memorandum observes, "success has been achieved by men who, while in no way inferior in courage, devotion, and self-sacrifice to their brethren elsewhere, have received a scientific training." It is pointed out that it is admitted on all sides that this country has suffered checks since the war began, due directly as well as indirectly to a lack of knowledge on the part of the legislators and of administrative officials of "science" or "physical science," meaning thereby the ascertained facts and principles of mechanics, chemistry, physics, biology, geography, and geology. As a curious instance of ignorance, the case is quoted of the public statement by a member of the Government, unchallenged when made, that his colleagues should be excused for not having prevented the exportation of lard to Germany, since it had only recently been discovered that glycerine, used in the manufacture of explosives, could be obtained from lard. Yet the chemistry of soapmaking and the accompanying production of glycerine is very ancient history. The time certainly seems to have come when officials of all kinds, no less than members of Parliament, should be as much ashamed of ignorance of the commonplaces of science as they would now be if found guilty of bad spelling or arithmetic.

The contention that our success now and in the difficult time of reorganization after the war must depend largely on the possession by the leaders and administrators of the country of adequate knowledge of scientific method and facts and of the habit of promptly applying known means to known ends is a statement so obvious that the fact that it should be thought necessary to make it is in itself proof of our backward state. It is, indeed, discouraging and somewhat pitiable to watch the operation of a mind of great natural endowments, tempered by the highest education the public schools and the old universities afford, attempting to handle a subject demanding a knowledge of the principles, facts, and methods of science. One can imagine the contempt which would have been felt for such a system of education by Greeks of the great period.

For a remedy the memorandum looks to a reform in the system of higher education both in the universities and in the schools which prepare boys for them. The one and effective way of giving the nation both better educated civil servants and a true and reasonable appreciation of science in all classes is, the committee considers, in the hands of the legislature, and of it alone. It must direct the Civil Service Commissioners and the Army Examination Board to give a preponderating, or at least an equal, share of marks in the competitive examinations to natural science subjects, proper safeguards being taken to make them tests of genuine scientific education, and not an incentive to mere cram: Natural science has been introduced as an optional subject for the Civil Service examinations, but only one-fourth of the candidates offer themselves for it; the reason is that it does not pay, since in Latin and Greek alone, including ancient history, they can obtain 3,200 marks, while for science the maximum is 2,400, and can only be obtained by a candidate who takes four distinct branches of science. Science has only been made compulsory at Woolwich within the last few years; for Sandhurst it still remains optional, and this college is probably the only military institution in Europe where science is not included in the curriculum. A result of this system of education, not merely upon the candidates but upon all the great schools of the old universities which necessarily, as things are at present arranged, work with them in aim and interest, is neglect of the study of the natural sciences.

The memorandum concludes by an appeal to the electorates to insist that candidates for their suffrages should pledge themselves to aid by legislation in bringing about a drastic reform in the scheme of examination for all the public services in the sense indicated. The memorandum is signed by a large number of men of science, mostly the seniors. The list includes the names of Sir T. Clifford Allbutt, Sir William Osler, Sir Henry Morris, Sir John Williams, Sir Ronald Ross, Professor Leonard Hill, Professor E. H. Starling, Dr. A. E. Shipley (Cambridge), Professor G. C. Bourne (Oxford), Professor J. C. Ewart (Edinburgh), Professor S. J. Hickson (Manchester), and Professor J. A. Thomson (Aberdeen), so that in biology alone it is fairly representative of all parts of the country, but though it contains the names of two peers—the Earl of Berkeley and Lord Rayleigh—it does not contain the name of a single member of the House of Commons.

Side by side with this appeal in the newspapers of Wednesday appeared a report from the Committee on Retrenchment in Public Expenditure, recommending the closure of the national museums in the capital of the empire in order to effect a saving estimated at £50,000 a year. The main argument, however, seems to be that the closure will liberate a certain number of policemen, caretakers, and cleaners, who could be employed in other Government departments. This second reason is justified by the incidental assumption that the staffs of museums are "employed on unnecessary work." This phrase, of course, begs the whole question, and we cannot doubt that in regard to the Natural History Museum at least the decision is most unfortunate. That museum is a great educational institution, and to mention only one practical point, it seems a pity to deprive soldiers who may have to serve in tropical and sub-tropical countries of the opportunity of studying the admirable large scale models of parasites, such as the malarial parasite and the trypanosome, and the insects by which they are conveyed, displayed in the central halls of the museum.

THE CENTRAL PENSION COMMITTEE.

THE Prince of Wales, who came home on short leave on January 30th, presided in his capacity as chairman over a meeting on February 1st, attended by the members of the Statutory Committee appointed to carry out the provisions of the Naval and Military War Pensions Act, and also by the First Lord of the Admiralty, the Minister for War, representatives of many organizations for the benefit of crippled men, of Government Departments, and of local administrations. The Prince, in a very lucid speech, first sketched the history of what had been done in the past with regard to naval and military pensions, pointing out that until the Transvaal war the State had made no provision for widows and dependants. The weekly pensions since granted out of the taxes of the country were supplemented out of voluntary funds administered by the Royal Patriotic Fund Corporation. In this war, not only the rank and file, but also the officers, and even the higher commands, were drawn from all classes of the community, and in these new situations the State had been obliged to regard the problem of the widow and dependant, and the still more difficult problem of the disabled, whether from wounds or disease, from a different aspect. Parliament, expressing the will of the people, had decided that pensions and allowances for widows and dependants, and for the disabled, should be given on a higher scale, and should be paid as of right through the usual State departments, but if the rule of equality of sacrifice was followed it would be necessary to supplement these State pensions in some cases. If we were really as a nation to love and honour our stricken heroes and see that they were provided not alone with pensions, but with employment suited to their new conditions, and, if necessary, trained, it would be essential, in order to provide systematically for the health, training, and employment of disabled officers and men after they had left the service, that the whole country should be covered by a network of machinery capable of working in harmony, until, after many years, the last victims of the war had ceased to be. The Pensions Act enjoined on the Central Statutory Committee as its first duty the formation of a committee for every county and county borough, and for every borough and urban district having a large population. It was not intended that the Statutory Committee should impose hard and fast limitations of a uniform character upon the various local authorities. The promised State grant of one million to start the work should be used, in the wealthier areas at all events, to supplement and stimulate, not to supplant and suffocate local efforts and local generosity. As showing the magnitude of the task, the Prince said that the total number of all ranks killed in the South African war was 21,942; the total number of all ranks killed in the present war was already 128,138. The total casualties in all ranks in the South African war was 44,876; in this war already 549,467. Mr. Balfour, in moving a vote of thanks to the Prince, said that the scheme was to combine in one great system all the advantages of central organization with those of local organization and charitable assistance. He believed that if the machinery set in motion by Parliament were worked as it might be worked it would be possible, if not to avoid all mistakes, at least to mitigate the inevitable sufferings of the men who defended the interests of the empire and those dependent on them. Earl Kitchener, who seconded, said that the Prince's experience at the front had enabled him to appreciate how great would be the demands on our humanity, our patriotism, and our sense of gratitude. The vote was carried by acclamation, and thereafter a business meeting of the Committee was held, at which it was resolved to ask the local committees to agree on a standard of relief and to issue a model scheme.

THE ATTESTED MEDICAL MAN.

IN view of the answer recently given in the House of Commons by Mr. Walter Long to a proposal made by Mr. King that medical men and dentists should be exempted from the provisions of the Compulsion Bill, it is well to call the attention of members of both professions to their present position as far as we are able to gather it. It is known that a certain number of medical men, both married and single, attested under Lord Derby's original scheme; and it is probable that the same remark applies to the dental profession. With regard to medical men who attested, the official statement by the Army Council, published in the *BRITISH MEDICAL JOURNAL* of January 15th last (p. 102) has made clear the course of action that they should pursue. They have been told by the Army Council that they should enrol with the Central Medical War Committee or the Scottish Medical Service Emergency Committee, as the case may be, by signing an application for a commission in the R.A.M.C., and leave it to the committee to call upon them for service if and when they are required. When they have enrolled they will receive from the committee a certificate of enrolment; and if they are called up in the group to which they belong under Lord Derby's scheme, they must produce to the recruiting officer their certificate. This will exempt them from service in the combatant ranks, and it will be left to the medical war committee to call upon their services when necessary. Under the Military Service Act members of the medical and dental profession, who are single and under 40 years of age, will be attested compulsorily; as a result these men will be liable to be called upon to take service in a combatant capacity. It is highly important, therefore, that all medical men, and such members of the dental profession as hold a medical qualification, and have under the new Act become liable for service, should forthwith enrol with the committee of the county to which they belong. In this way, whenever the time arrives for the attested group to which they belong to be called up, they will be armed with a certificate of enrolment, and so able to place their position before the recruiting officer. Unless they are prepared in this way, they may find it extremely troublesome, if not difficult, to escape from combatant service. The effect on the treatment of the civilian population may be even more serious than upon recruiting for the R.A.M.C.

THE MILITARY SERVICE ACT.

THE Military Service Act, 1916, which has just been passed, directs the establishment of three grades of tribunals for dealing with applications for exemption from its provisions—local tribunals, an appeal tribunal for counties or groups of counties, and a central tribunal. The local tribunals are to be appointed by the local registration authorities under the National Registration Act. There are four grounds for an application for exemption to a local tribunal: (1) That it is expedient in the national interests that the individual, instead of being employed in military service, should be engaged in other work; (2) that serious hardship would ensue if he were called up, owing to special financial, business, or domestic obligations; (3) on the ground of ill health or infirmity; and (4) on the ground of conscientious objection to undertaking combatant service. The local tribunal, if it considers the application established, will grant a certificate of exemption. A Government department may, after consultation with the Army Council, grant certificates of exemption to men, or classes or bodies of men, in the employment of the department, or engaged or qualified for employment in any work within the sphere of the department certified by it to be of national importance. There is an appeal from the decision of the Government department to the Treasury, whose decision will be final. A certificate of exemption may be absolute, conditional, or temporary, and

in the case of application on conscientious grounds may take the form of exemption from combatant duties only, or be conditional on the applicant being engaged in some work which, in the opinion of the local tribunal, is of national importance. A certificate granted on the ground of special financial, business, or domestic obligations must be a conditional or temporary certificate only. There is an appeal from the local tribunal to the county appeal tribunal, and the President of the Local Government Board has issued a circular letter to the chairmen of county councils, lord mayors and mayors, asking them to take steps to submit a list of suitable persons to act on the county appeal tribunal. It will be the duty of the appeal tribunal to afford an opportunity to the parties to any appeal to appear in person. The circular letter points out that it is of the highest importance that the tribunal should command the confidence of the community, and that, inasmuch as the labouring population will have a large interest in the questions to be determined, a fair proportion of the members of the tribunal should be direct representatives of labour. It is further suggested that at least one member of the tribunal should have legal training and experience, and that women should be placed upon the tribunals. No person whose name is suggested should be a man of military age who has not been attested or pronounced physically unfit for military service. The members of the appeal tribunals will be appointed by His Majesty, as will also be the members of the central tribunal for Great Britain, to which appeals may be taken from the county appeal tribunal. In grouping counties for the purpose of appointing appeal tribunals the county boroughs within the area are included, with the exception that for London and for Middlesex there will be separate tribunals.

SECONDARY CLOSING OF WAR WOUNDS.

CARREL, Dehelly and Dumas presented to the Paris Academy of Medicine on January 18th a paper on the secondary closure of war wounds, in a continuation of the work already reviewed in these columns, on the abortive treatment of infected wounds based on the employment of sodium hypochlorite prepared according to Dakin's formula. In this earlier paper, as evidence of the utility of the method, cases were cited of the union by first intention of wounds which had been closed after a relatively short but vigorous course of antiseptic treatment. More extensive experience with the method led the authors to believe that such secondary closures of wounds was a general method of great value. Free incision of wounds, while essential for their successful exploration and for the removal of foreign bodies, had serious drawbacks by prolonging subsequent treatment and interfering with normal cicatrization. The cicatricial tissue eventually filled the spaces between the muscles, aponeurosis and skin, and the surfaces of these latter structures were apt to become adherent by a solid cicatricial mass of new tissue which impeded or even altogether prevented muscular contractions. To avoid this, an attempt was made to draw the various corresponding surfaces of a wound together at an early date so that the development of new connective tissue was reduced to a thin sheet, which did not seriously interfere with muscular function. This they found could be accomplished with almost constant success by employing the following method: Within a few hours of their infliction the wounds are opened up so as to admit of careful exploration, cleansing and haemostasis. During the following days the hypochlorite solution was instilled constantly by the technique already described in these columns. After all signs of infection had disappeared and successive bacteriological examinations had indicated a progressive diminution of bacteria, ending in their disappearance, the wounds were closed. This was usually done between the fourth and tenth day. When infection

was avoided, it was found that the various tissues preserved their characteristics practically unaltered during the period of antiseptic treatment, and the authors stated that wounds so treated were comparable in every way with fresh operative wounds and united by first intention. To effect this, it is essential that all parts of the wound should be brought into apposition as exactly as possible. The wound should be closed with adhesive strips $2\frac{1}{2}$ c.cm. to 5 c.cm. broad. In general they preferred to avoid sutures. The facility with which direct union was obtained in the majority of cases was ascribed to good preliminary antiseptics. The authors believe that many wounds can be closed secondarily at a later stage with advantage. As a rule the skin is adherent to the subjacent structures and granulation tissue has filled the intermuscular spaces. In order to close such wounds it was found necessary to loosen the skin from the edges of the wound and to curette the granulation tissue; the various parts were then brought into apposition and the skin closed with sutures. These procedures, it was stated, materially hastened the rate of recovery, and did much to avoid stiffness and atrophic changes. The authors reaffirm their belief in the efficacy of hypochlorite instillation, stating that it alone permitted of a sufficiently rapid sterilization, so that in most cases the wounds could be closed before the tenth day. In an interesting discussion following the presentation of the paper M. Dastre expressed the opinion that union of wounds by first intention could not be regarded as proof of sterilization. He and some other speakers expressed the opinion that the beneficial effect of hypochlorite was due to its ability to clear away damaged and necrotic tissue and to destroy toxins rather than to its antiseptic action. M. Pozzi warmly advocated the use of hypochlorite, and adversely criticized some inconclusive experiments of Delbet on the germicidal action of hypochlorites. M. Quénu and M. Bazy considered that good surgical technique and free irrigation were of more importance than the employment of hypochlorite as an antiseptic.

THE CONTROL OF TUBERCULOSIS IN WAR TIME.

THE concentration of national energy upon the provision of naval and military requirements has of necessity lessened the force of the movement, which was steadily gathering strength before the war, for the eradication of tuberculosis. Although lessened, the work has not been suspended, and it would seem to be a fitting time to take stock, as it were, of the experience already gained, and to endeavour to come to some agreement as to the best lines to pursue in the further progress of the campaign, and as to the manner in which economy can be practised with as little loss of efficiency as possible. With this object the *British Journal of Tuberculosis*, in its number for January, 1916, has collated the views of several physicians and medical officers of health who had been invited to contribute to a symposium of representative opinion as to the present needs and future prospects of the antituberculosis crusade. Appropriately headed by a word of advice from the Regius Professor of Physic in the University of Cambridge, the symposium contains many brief but valuable annotations. Sir Clifford Allbutt comments upon the futility of expenditure of large sums upon systems of cure while day by day fresh infections are multiplying the victims of the disease. He would evidently prefer to see such expenditure taking the form of provision for segregation of the infective cases. Such provision, however, even in the most peaceful times, must of necessity involve questions of personal freedom and respect for property which could only be solved by legislative enactments, wholly impracticable in existing circumstances. His further advice—that existing machinery only should be employed at the present time, and pioneer work neglected—is quite in accordance with the views expressed by others, including

Dr. Hope, M.O.H. Liverpool, who has found it necessary to give up examination of patients after treatment and examination of contacts, from sheer lack of medical assistance to carry on the work. The sanatorium question is presented in a very practical form by Dr. Williamson of Edinburgh, and the figures with respect to cost which he records deserve thoughtful consideration. It is obvious that very large sums are being spent in "improving" the health of persons who can only return to the very conditions of life under which their health became impaired. He also would prefer to see such expenditure allotted to preventive rather than to curative measures. Dr. Hyslop Thomson in like manner would exercise economy by reduction of sanatorium treatment, and would endeavour to increase hospital accommodation both for early and advanced cases. An important question is raised by Dr. Jane Walker, who advocates residential sanatorium schools for tuberculous children, even if sanatorium treatment for adults be suspended. The general outcome of the man's opinions expressed in the symposium, in addition to those already referred to, would seem to be that at the present juncture it is essential that the work of the tuberculosis dispensaries should not be relaxed, but that more attention should be paid to domiciliary treatment and to the control of infected children, especially as this can often be done by partially trained nurses or visitors. Segregation of the advanced case is as desirable as ever, but is as far as ever from practical realization. Expenditure upon sanatorium treatment should be greatly curtailed, and strictly limited to the treatment of cases in which real arrest of the disease may reasonably be expected.

THE INSURANCE COMMISSIONERS AND MEDICAL RECRUITING.

IN reply to a remonstrance addressed to him by a medical practitioner the clerk of the Middlesex Insurance Committee has written to explain that the circular letter to which we called attention last week (p. 175) was not intended to mean quite what it appeared to mean. He says that the Committee is second to none in its desire to give the greatest possible assistance to the army, and only asks that when a doctor offers his services to the R.A.M.C. it may have an opportunity of seeing that proper arrangements are made for the treatment of the members of the civil population he had undertaken to attend. In some cases, he states, it has happened that the first intimation the Committee received that a doctor had joined the R.A.M.C. was that a patient had called at his surgery and found it closed. The circular letter was sent with the view of avoiding similar circumstances arising in the future. We hardly think that this excuses the terms of the letter. It may have happened occasionally that all the patients of a panel practitioner have not become aware of the departure of the doctor, but the public is very oblivious, and does not always read notices with sufficient attention. We believe that the arrangements made by the Central Medical War Committee are sufficient amply to prevent any real inconvenience. It is, of course, necessary that every doctor of military age (that is to say, under 45) and physically fit should enrol with that Committee, when, after consultation with the local Medical War Committee, all arrangements will be made for the conduct of the departing practitioner's practice with the least possible inconvenience to his patients and the least possible loss to himself.

WE regret to have to record the deaths of Mr. Stanley Boyd, senior surgeon, to Charing Cross Hospital, on February 1st, and of Mr. Charles Stonham, C.M.G., senior surgeon to Westminster Hospital, which occurred on January 31st as the result of an illness contracted while serving, with the rank of Colonel A.M.S., as consulting surgeon with the forces in Egypt. We hope to publish obituary notices in a future issue.

Medical Notes in Parliament.

War.

Medical Students.—On January 27th Mr. Cantley asked a question as to the employment of medical students in the 1st Eastern General Hospital (Cambridge), and inquired whether the employment of senior students in military hospitals in this country could be extended without requiring them to enlist as privates in the R.A.M.C., so setting free qualified medical men now working in military hospitals for other duties. The Financial Secretary to the War Office said that the employment of students in the 1st Eastern General Hospital was a matter of private arrangement between the Cambridge school and the officer commanding the hospital. It was possible that senior students might do work in military hospitals elsewhere under similar arrangements, but if they had not completed the prescribed period of their medical studies they would not be exempt from military service under Lord Derby's scheme. Students employed in this way could not undertake the duties of qualified medical men.

Physical Unfitness.—On January 27th Mr. Tennant said that, in view of the fact that the decision to reject men as the result of a medical examination under Lord Derby's scheme had in many cases to be reached hurriedly, it might be necessary to call up such men for a fresh medical examination. Every effort would be made to carry out the medical examination of recruits as expeditiously as possible, so as to obviate any inconvenience to them or their employers, but the number of doctors available was limited, and the work must be done efficiently and not over-hurried.

Medical Appliances for Military Hospitals.—Mr. Tennant stated, on January 26th, in reply to Mr. R. Gwynne, that there was no regulation in military hospitals directing that medical appliances should be ordered only from Woolwich, as the question suggested. The regulations provided for local purchase under urgent circumstances, but this was a more expensive method of meeting requirements than by obtaining what was wanted from War Office contractors.

Wounded Soldiers: Selection of Hospitals.—Mr. Barnes, on January 27th, asked a question as to the inconvenience and cost to the relatives of wounded soldiers sent to hospitals far removed from their homes. The Financial Secretary to the War Office said that as far as possible the existing practice was to send wounded men to hospitals near their homes, but it was not possible to send every man to the hospital to which he would prefer to be admitted. Some were too ill to stand the fatigue, others were earmarked overseas for admission to hospitals specially set apart for the class of sickness or injury from which they were suffering. It was also necessary to distribute men in ambulance train loads—that was to say, in groups of a hundred or so, as railway conditions did not permit of the disturbance of traffic which would arise from a train dropping cases here and there between the port of disembarkation and the ultimate destination. Consequently some men must find themselves in hospitals removed from their homes, but arrangements could generally be made for the patient's transfer to a hospital near his home so soon as he was fit to travel, provided the medical authorities were satisfied that the case was one suitable for treatment in the hospital to which the transfer was requested.

Army Medical Services (Advisory Board).—In reply to Mr. Lynch, on January 26th, Mr. Tennant said that the Army Medical Service Advisory Board exercised no control, but advised the D.G.A.M.S. The value of the opinions of individual members of the Advisory Board was in no way affected by the military positions they now occupied. Mr. Tennant, in reply to another question, said that the Board was not instituted by Order in Council. Those of its members who received pay were paid from army funds. The decisions of the Directors-General in England and France were not subject to the concurrence of the Board. Mr. Lynch asked whether the Board had done the service for which it was instituted. Mr. Tennant replied that it had in peace time. In reply to a further suggestion whether, as the Board did not meet, steps would be taken to eliminate the expense of keeping up a

board whose advisory functions had ceased since the war broke out, Mr. Tennant said that the non-official members of the Board were employed in an advisory capacity. Those in France were similarly employed as an advisory board to the Director-General of the Medical Services.

Total Casualties.—On January 27th the Prime Minister furnished the following statistics of the casualties in all fields of operations down to January 9th. The total is 21,240 in excess of that given by the Prime Minister for the casualties to December 9th, 1915. The number of killed shows an increase of 8,215, and of wounded 14,525; the number of missing shows a decrease of 1,500. The figures are as follows:

France.			
	Officers.	Other Ranks.	
Killed...	5,318	82,130	
Wounded...	10,217	248,990	
Missing...	1,691	52,344	
Total...	17,046	383,464	
400,510			
Dardanelles.			
Killed...	1,745	26,455	
Wounded...	3,143	74,952	
Missing...	353	10,901	
Total...	5,241	112,308	
117,549			
Other Theatres.			
Killed...	918	11,752	
Wounded...	816	15,165	
Missing...	101	2,656	
Total...	1,835	29,573	
31,408			
Grand Total.			
Killed...	128,138		
Wounded...	353,283		
Missing...	68,046		
549,467			

Scientific Research.—Sir Philip Magnus asked the Prime Minister to consider the desirability of appointing a mixed committee of M.P.'s and others having a practical knowledge of the subject to inquire into the organization of education in this country, and to report as to whether, having regard to the experience gained in the operations of the war and to the new social and economic conditions that may result when the war is over, changes may be advisable in our national system of education with a view to establishing, without unduly interfering with other aims, a closer connexion between commercial and industrial requirements and the teaching provided in educational institutions, and in order to secure such further development as may be found necessary of existing facilities for scientific research, and the better training of all classes of the population for the activities in which they may be severally engaged. The Prime Minister said that the scheme of educational development which had been foreshadowed was last year reconsidered in the light of existing conditions and the probable requirements of the country after the war. Partial effect had been given to the scheme, which was concerned with the special scientific and industrial interests. The President of the Board of Education would be happy to consult all persons or bodies in a position to give advice on this matter, but it was not thought necessary to set up a committee.

Effect of Liquor Control Regulations.—On January 26th the Parliamentary Secretary to the Munitions Department (Dr. Addison) stated that the average weekly convictions for the principal areas scheduled in England, comparing the four weeks ending December 19th with the four weeks preceding the Order, had fallen approximately 50 per cent. The reductions had been as follows:

	Per cent.
North-east Coast area ...	37
Liverpool and Mersey area ...	46
Midland area ...	63
West Riding area ...	53

The figures in Scotland, although less satisfactory, showed a substantial reduction, and, as the result of an inquiry recently held in Glasgow, there seemed no reason why results as satisfactory as those in England should not be obtained in Scotland. Although detailed figures were not available, he was informed that the more serious offences connected with or caused by drunkenness had diminished in almost all areas even more rapidly than the more venial cases.

THE WAR.

WAR, DISEASE, AND A MUSEUM.

(From a Correspondent in Northern France.)

I SEE that at home you are talking of organizing science. Out here we have done so already. That "we" of course means "they." In the evening, when the day's work is over or its journey done, I think I have helped in the organizing process. In the morning—at the hour of wonder if one's boots have dried—I know that I have not. But why explain? If the fly always tries to alight on the fastest-moving wheel, who shall blame it for a little pride in its speed?

Out here Organized Science meets one right and left. It is of two main types, and the organization mainly lies in endeavouring to secure that the resources of the one shall assist the practice of the other.

Scientific instruments of destruction require human operators, and to help to keep these operators healthy is the task of preventive medicine. Never, perhaps, in any previous war has this been so thoroughly recognized, and never before has preventive medicine so well justified its title. Chemistry, pathology, entomology, and bacteriology are all four working in its service, and the result is real and effective sanitation.

There have certainly been set-backs: "trench foot," "war nephritis," and "trench fever" are perhaps instances of them; but the radical cause of the first is for the most irremovable, and the causes of the two latter have so far baffled research. Meantime it is something to the good that the diseases themselves should have been differentiated from their congeners, and that of the blind alleys that confuse the path towards discovery of their initial cause, many at any rate have been closed.

There has also, it is true, been plenty of sickness, but the total is marvellously small considering the environment and weather in which so much of the war in Flanders and the Aisne valley has been fought. Furthermore, it has to a great extent been sickness of a domestic rather than a military order. What one used to call the water-borne diseases have throughout been kept well under control; the known dietetic diseases have been almost conspicuous by their absence; dental troubles as a source of wastage have been handled with success; and the disorders of tropical or semi-tropical origin which the Indian troops might have been expected to import have almost failed to put in an appearance.

So far, in fact, the morbidity complexion of the whole operations in France during the past sixteen months has singularly differed from that of previous campaigns; in all these, sickness proved out and away a much more formidable source of wastage, both temporary and permanent, than the weapons of the enemy.

All this is already, I suppose, well known, as also are the more conspicuous factors in bringing about so satisfactory a result: The guarding of water supplies, and the careful treatment of all those of doubtful origin; the testing at the hygiene laboratories not only of rations, but of all food known to be used by the troops; the provision of bath-houses and of laundries, and the issue of parasite-free clothing and blankets; the cleansing and disinfection of billets; the destruction of garbage and of manure or other possible breeding places for flies; the assiduous attention to the cleanliness of camps; the employment of sanitary squads at railheads and of sanitary sections at bases and corps head quarters; the isolation of patients suffering from infectious disorders, as also contacts, whether of the Expeditionary Force or of the civil population brought into relation therewith; the steady practice of anti-typhoid inoculation (a vaccine valent also against the paratyphoids is now being used); the chronic search for "carriers" of all orders, civil as well as military; the instant investigation, with the help of the mobile and of the base pathological laboratories, of all outbreaks of disease, whether amongst the troops in the fighting zone or of those on the lines of communication or elsewhere; the maintenance of spot maps, charts, and tables, revealing the health-history of every unit in the field; and the co-ordination of all work and the due stimulation of all workers by the principal pathologist and the principal sanitary expert on the staff of the D.G.M.S.

These no doubt are the main factors, but there is also another circumstance which has probably exercised a good deal of influence.

For years past the general principles and demands of hygiene have been gaining increasing acceptance among laymen as the result of a campaign which has been especially active in the army. Consequently the Expeditionary Force contains quite an effective proportion of officers, non-commissioned officers, and men who, unlike their predecessors in South Africa and elsewhere, are far from regarding sanitary counsels as mere medical fads, and realize that rules regarding sanitation are quite worth keeping if circumstances are in the least degree favourable thereto.

This spirit, if it exists, must certainly have contributed to the success in question, and among other circumstances there is one—a little straw, if you please—which to my mind renders its existence indubitable.

Many of middle age will remember the old Parkes Museum in Margaret Street, the collection of embryo sanitary appliances, models, and illustrations of ideas, around which grew up the collection of the Royal Sanitary Institute now in Buckingham Palace Road. Well, some time ago I came across a place of exactly the same kind out here. It had already been open some months, and, as far as I know, it is open still. The foundation of the Parkes Museum was due to the desire to commemorate one who had done much for the Army Medical Service. This said museum owes its creation to the enterprise of an army medical officer. Many of the objects displayed were those used by himself in his work as a sanitary expert, but the bulk of the exhibits, as also the bulk of the visitors, came from the battalions resting in the neighbourhood from a turn of duty in the trenches. How can one account for the existence and popularity of such a place in a townlet within a half a dozen miles of the fighting line except on the supposition that the spirit of hygiene has a real hold on the army as a whole?

To me personally this fighting zone museum was all the more striking because I well remember a foreign station visited by men and officers from both east and west, where there were the same needs as here, and the same materials for meeting them existed. Yet that station in all the years that I knew it never improved on its original highly imperfect sanitary appliances, or seemed to realize any need for doing so.

But in those days Hygiene had not acquired a capital letter, and as a cult had barely any existence either in professional or lay circles. That the present position is very different was proved by the multiplicity of ideas illustrated at the exhibition mentioned.

A detailed catalogue was in process of compilation, I understood, and excerpts from it will no doubt find place in the eventual medical history of the war. Meantime I can merely say that the exhibits as a whole seemed to fall into three main classes—appliances for storing and safeguarding food, ways of building latrines and latrine seats, ways of getting rid of refuse—and that in all cases the materials intended to be used were those to be found in every military camp, for example, empty oil drums, biscuit and jam tins, packing-cases, and wire.

In the first class, for instance, I recall a packing-case turned into a fly-proof food store by curving the edges of its open end and covering this with a weighted curtain. In the second class, Surgeon-General McPherson's plan, by which any user of a latrine becomes his own conservancy man, urine and faeces being kept separate and both being destroyed forthwith by fire. In the third, a series of destructors and incinerators built out of practically nothing beyond empty tins, ashes, and clay. These were shown in actual operation, doing all the work created by a large army of men, and doing it very effectively.

Other forms of refuse destructors on view included one which was especially attractive on account of its simplicity. It was, however, best suited for dealing with bulky refuse, such as manure, while the two former mentioned will destroy effectually anything and everything, including the contents of latrine buckets.

The method consisted in crushing a quantity of old wire or iron bands into a heap measuring 18 in. or so in height and 3 ft. or 4 ft. in diameter, and using this as the foundation for a rubbish heap. Such refuse heaps

once set alight burn steadily and continuously for weeks, despite falling rain and whatever additions be made to them. After a time fine ashes collect round the edges in sufficient quantity to choke the draught, and the central wire core can then be pulled out and used to build a fresh pyre.

There was much else that was interesting, and this exhibition, in conjunction with other circumstances, seems to justify a remark to the effect that in the British army the cult of Aesculapius is replaced by the worship of Hygeia, whose temple is the battalion cookhouse and the camp latrine. In its original form it was made, I believe, by an Irish M.O. now in the Near East.

THE DUTIES OF A SANITARY SECTION IN THE FIELD.

We are indebted to Major Charles E. Goddard, M.D., R.A.M.C.(T.), for the following notes:

From time to time we hear of the remarkable work that is being accomplished by different branches of the sanitary service, and it may therefore be considered an opportune moment to refer to the special work of a sanitary section.

Though not actually a new unit in army establishment, a brief note as to its source, distribution, and special duties will afford many points of interest to the student of army sanitation.

At the outbreak of war, or soon afterwards, instructions were received from the War Office to increase the strength of the London (Territorial) Sanitary Companies by enrolling new companies with a view to the formation of sanitary sections for service in the field. So successful was the response, and so efficient the training and equipping of the men, that every division of the army has been supplied with one of these sections.

Each of the sections has a personnel of twenty-six men, not including the Army Service Corps men—that is, one officer, twenty-five non-commissioned officers and men. As to the choice of officers, preference has always been given to medical men who are medical officers of health, or who hold diplomas of public health or are bacteriologists; a few are sanitary engineers, and even architects. A large percentage of the non-commissioned officers are sanitary inspectors, and among the rank and file are found many plumbers with sanitary diplomas, carpenters, schoolmasters, men of all ranks of life, graduates in honours even from Oxford, Cambridge, and other universities, solicitors, chemists, and representatives of all the professions and trades. In this way it will be seen that there is no difficulty in providing for each section a sufficient number of disinfectors, interpreters, carpenters, cooks, builders, and, in fact, supplying any man likely to be of service in the field.

The first twelve sections, with twelve lorries full of equipment, were sent to France on Christmas Day, 1914, with the senior officer of the 2nd London Sanitary Company in command. Each division was then, and is now, supplied with one section; the A.D.M.S. of the Division being responsible for their work.

Such work includes bathing of the troops in thousands, disinfecting of the men for vermin after enteric, cerebrospinal fever or other infectious diseases; disinfection of all clothing and blankets; the purification of water; the draining of farms and billets; making, or giving instruction for, the erection of destructors or incinerators, ablution places, grease traps, urine pits, filters, fly traps, and, in fact, making every kind of installation, structure, or appliance that appertains to sanitation in the field.

It would be impossible to enter into details of all the good work done by these men, but reference may be made to the baths that were used in Ypres, for example in February, 1915. Here, about two miles from the trenches, was a massive red building, built and endowed by the late King of the Belgians as a school or reformatory. It had been badly shelled, but the sanitary men soon found tubs and old baths and pumped water into the boilers in the kitchen, and had excellent baths going in a few hours. Everything was carried out with system and dispatch. None of those who were there last February will forget the delight of the men at the sight of the hot baths and the hot beef-tea on coming out of the trenches, or hearing their witty comments, and seeing them in such high spirits in spite of all they were going through.

At last the enemy got the exact range of the building. The position became untenable, and other baths had to be found at breweries and other places further back. Now this huge building and the whole city of Ypres has been entirely destroyed.

Sometimes these sections are sent to the trenches. On one occasion one of the sections was asked to volunteer to help to collect the wounded who were lying outside the trenches in too great a number for the field ambulance to deal with. Every member offered and went, gaining the thanks of the general through the A.D.M.S. the next day. On another occasion they were required to take an anti-gas apparatus to the trenches, but the enemy attack was so furious that night that the apparatus had to be abandoned, and the men remained to help the doctors to treat the wounded. They had a terrible experience, and one of their number was killed. These sanitary men are not really expected to work in the firing line, but they are sometimes required to work in the reserve trenches, and occasionally get wounded on purely sanitary work.

These are only a few things which have come to my personal knowledge, but one heard them spoken of as ever willing, nay, desirous, of helping their fighting brothers in every way possible. It might have been known that such would be the case, not so much from the rank of life from which these sections are formed, but because they felt that, though many of them had had no military training, they could not be more usefully employed. The Commander-in-Chief in his last two dispatches has recognized their value by mentioning no less than thirteen of their officers and quite a number of their men.

It is good to think that there is such a body of experts who can assist the R.A.M.C. officers in watching over the health and sanitation of our brave fellows at the front.

CASUALTIES IN THE MEDICAL SERVICES.

Killed in Action.

LIEUTENANT ALFRED NOEL GARROD, R.A.M.C., 100th Field Ambulance, was killed by a shell in France on January 26th. He was the eldest son of Dr. A. E. Garrod, physician to St. Bartholomew's Hospital, and grandson of the late Sir Alfred Garrod and Sir Thomas Smith, Bt., K.C.V.O. He received his education at Marlborough, Cambridge, and St. Bartholomew's Hospital, and took the degree of B.A.Camb. and the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1914. He had held the office of house-surgeon at St. Bartholomew's Hospital. Lieutenant Garrod received his commission (temporary) in the R.A.M.C. in July last, and went to France in November with the 100th Field Ambulance. During December he was attached to the 22nd Royal Fusiliers, but subsequently rejoined the field ambulance, and was serving with it when killed. His second brother, Lieutenant T. M. Garrod, Loyal North Lancashire Regiment, was killed on May 10th, 1915.

Died on Service.

Lieutenant-Colonel Henry Bridges Yates, of the Canadian Army Medical Corps, died in the Canadian Military Hospital at Ramsgate in January, aged 60. He was born in May, 1855, the son of Henry Yates of Brantford, Canada, was Medical Officer of the 3rd Victoria Rifles, Montreal, came to England as A.D.M.S. of the 4th Montreal Canadian Division, went to France in May as second in command of the No. 3 Canadian General Hospital, and was invalided to England early in December. He married in 1896 Miss Alice Bunting of Toronto, and leaves a widow and two sons, one of whom is now serving in the Canadian contingent. He was a Knight of St. Olaf of Norway, and a Knight of Grace of St. John of Jerusalem.

Wounded.

Captain H. H. B. Cunningham, R.A.M.C.(T.F.), Mediterranean.

Captain J. E. T. Jones, R.A.M.C. (temporary), France.

Captain T. L. Spackman, R.A.M.C. (temporary), Mesopotamia.

Captain H. F. Wilkin, R.A.M.C.(T.F.), attached 5th Durham Light Infantry, France.

Lieutenant W. Campbell, R.A.M.C. (temporary), Mediterranean.

Lieutenant T. E. Hammond, F.R.C.S., R.A.M.C. (temporary), Mediterranean.

Prisoners of War.

The *Times* of January 26th announces the release at Kolmaka, in the Cameroons, by the capture of that station on January 8th, of seven officers who were prisoners of war there. Among them are Dr. Lindsay and Dr. Trumper of the West African Medical Service, who were taken in October, 1914.

We are informed that Dr. Catherine L. Corbett, of the London Education Committee, who was serving with a hospital in Serbia, has been taken prisoner there. Dr. Elizabeth Brook, of the same service, who has also been serving in Serbia, has returned home.

DEATHS AMONG SONS OF MEDICAL MEN.

Adam, Alan Gordon Acheson, Captain 1/5th The Buffs (Weald of Kent), killed in action in Mesopotamia on January 21-22nd, was the fifth son of the late Dr. James Adam of Malling, Kent, and Mrs. Adam of Hythe, and was born in July, 1887. He was educated at Marlborough and Selwyn, Cambridge, took the B.A. degree in 1907, and passed the final law examination in 1910. He joined the 5th Buffs in 1911 while practising in Cranbrook. He left with his regiment for India in November, 1914, was shortly afterwards gazetted captain, and proceeded to Mesopotamia in December last.

Colson, Edward, Major 41st Dogras, eldest son of Surgeon-Major E. Colson, I.M.S. (retired), died in Mesopotamia on January 13-14th, of wounds, aged 41. He was born on October 29th, 1874, got his first commission in the South Wales Borderers, through the Militia, on December 7th, 1895, joined the Indian army on January 29th, 1899, became Captain on December 7th, 1904, and Major on December 7th, 1913. He served in China in 1900, and received the medal.

Grimshaw, Ewing Wrigley, Lieutenant-Colonel 62nd Punjab, eldest son of the late T. W. Grimshaw, C.B., M.D., Registrar-General for Ireland, killed in Mesopotamia on January 21st, aged 48. He was born on February 10th, 1867, got his first commission in the Royal Dublin Fusiliers, through the Militia, on November 10th, 1888, joined the Indian army on June 14th, 1891, became Captain on November 10th, 1897, Major on November 10th, 1906, and Lieutenant-Colonel on November 10th, 1914. He served as Deputy Assistant Adjutant-General in India from 1901 to 1906.

Murray, Graham Dunmore, Second Lieutenant 2nd Battalion Northumberland Fusiliers, son of the late Dr. William Dunmore Murray of West Side, Clapham Common, killed in France on January 26th. He got his commission in March, 1915.

Skeen, Oliver St. John, Major 62nd Punjab, son of the late Surgeon-General William Skeen, A.M.S., killed in Mesopotamia on January 21st. He was born on November 2nd, 1874, entered the army on January 16th, 1895, became Captain on January 16th, 1904, and Major on January 16th, 1913. He served in the South African war in 1900-01 as a special service officer, taking part in operations in the Transvaal, in the Orange River Colony and in Cape Colony, and received the Queen's medal with four clasps; also in Tibet in 1903-4, at the action of Nyani, the operations round Gyantse, and the march to Lhasa, medal with clasp; and took part in the defence of the Suez Canal last February, after which he received the D.S.O.

Smith, Neville, Captain Durham Light Infantry, the son of Dr. and Mrs. G. H. Smith of Hull, was killed in France on January 26th; he was a black and white artist on the staff of *Punch*.

HONOURS.

The *London Gazette* of February 2nd contains a further list of awards and promotions for services in the field. The following are among the honours conferred on medical officers:

C.B.
Lieutenant-Colonel: W. W. Giblin (Australian A.M.C.).

C.M.G.
Colonel: C. H. Hale, D.S.O.

D.S.O.
Majors: W. R. Battye, M.B., F.R.C.S., I.M.S., and D. S. Skelton.
Captain: E. S. Phipson, M.B., I.M.S.

Military Cross.

Captains: J. H. Aikman, M.B. (temporary), G. D'R. Carr (temporary), C. C. Fitzgerald (T.F.), F. J. H. T. Frere, M.B., (S.R.), W. Rutherford, M.B. (T.F.), E. T. Brennan (Australian A.M.C.), C. W. Thompson (Australian A.M.C.).
Lieutenant: H. B. Atlee, M.D. (temporary).

The *London Gazette* of January 27th announces some additions to the list of officers mentioned in Viscount French's dispatch of November 30th, published on January 1st. Among them is Major G. W. G. Hughes, D.S.O., R.A.M.C.

The *London Gazette* of January 28th publishes a long list of officers mentioned for good service in the Gallipoli peninsula, in connexion with his dispatch of December 11th. Among them are the following medical officers:

STAFF.

Colonels: J. Maher, M. J. Sexton, and C. H. Hale, D.S.O., of the A.M.S.

Lieutenant-Colonels: G. St. C. Thom, D. S. Skelton, and W. M. B. Sparkes, R.A.M.C.

ROYAL ARMY MEDICAL COLLEGE.

Lieutenant-Colonels: D. D. Shanahan, H. M. Nichols, W. P. Gwynn, T. C. Mackenzie, D.S.O., J. F. M. Kelly.

Majors: A. M. McIntosh (temporary Lieutenant-Colonel), Benson, R. R. Lewis.

Captains: J. Y. Moore (S.R.), K. M. Levi (Australian A.M.C., killed), C. Cassidy, J. C. Young (S.R.), F. J. H. T. Frere (S.R.), A. Glen (S.R.), G. S. Pirie (S.R.), R. B. Lilly (temporary), G. D'R. Carr (temporary), J. H. Aikman (temporary).

Temporary Lieutenants: H. H. R. Bayley, W. Macdonald, H. B. Atlee, T. A. Peel (died of wounds), G. S. Goodwin.

ROYAL ARMY MEDICAL CORPS (T.F.).

Lieutenant-Colonels: T. Fraser, E. J. R. Evatt.

Captains: F. J. Green, G. Raymond, A. Findlater, P. S. Bedale, C. C. Fitzgerald, M. B. Rutherford, H. E. Quick, J. Macquarrie, W. R. Eristow.

AUSTRALIAN ARMY MEDICAL CORPS.

Lieutenant-Colonels: C. Garner, H. W. Bryant, A. H. Sturdee.

Majors: H. A. Pavell, L. W. Dunlop.

Captains: J. Bentley, E. T. Brennan, H. V. P. Conrick, A. L. Dawson, A. Y. Fullerton, C. W. Thompson, W. J. Stack, J. E. Dodds, L. St. V. Welch.

NEW ZEALAND ARMY MEDICAL CORPS.

Major: E. J. O'Neill.

Captains: K. McCormick, A. V. Short, R. N. Guthrie.

INDIAN MEDICAL SERVICE.

Majors: W. B. Battye, L. P. Brassey.

Captains: P. M. Rennie (1/5th Gurkhas), E. S. Phipson (1/6th Gurkhas).

INDIAN SUBORDINATE MEDICAL SERVICE.

Subassistant Surgeons: Ghans Muhammad, Sampuran Singh, Amar Nath Puri.

The list also contains the names of non-commissioned officers and men of the R.A.M.C., including the Special Reserve and Territorial Forces and of the Indian Subordinate Medical Service.

It is notified in the *London Gazette* that the King has granted to Lieutenant-Colonel Henry Edward Manning Douglas, V.C., D.S.O., R.A.M.C., Deputy Assistant Director of Medical Services, authority to wear the insignia of the fifth class of the Order of St. Sava, conferred upon him by the King of Serbia.

NOTES.

MEDICAL OFFICERS WANTED.

2/1st Home Counties Casualty Clearing Station.

Medical officers are required for this hospital. Applications to the Officer Commanding 2/1st H.C. Casualty Clearing Station, Surbiton.

Scotland.

The Lanarkshire Insurance Committee has adopted a resolution calling attention to the bad state of housing in the county and the decrease in the number of new houses being erected. It has been led to take up the matter owing to the increasing number of cases in which patients formerly discharged from sanatoriums for tuberculosis have applied for readmission in a more advanced stage of the disease. This disquieting circumstance is attributed to the bad houses to which the patients had to return when discharged.

THE HIGHLANDS AND ISLANDS MEDICAL SERVICE BOARD.

The Highlands and Islands Medical Service Board has issued a series of schemes for the several districts concerned. Each contains a statement as to the general conditions, and a schedule showing the area for which each doctor is responsible. The notice sets out that the persons eligible to receive medical attendance at modified fees are "the families and dependants of insured persons, uninsured persons of the cotter and crofter classes and their families and dependants, and others in like circumstances to whom the payment of the practitioner's ordinary fee would be an undue burden." The fee to be charged for the first visit is not to exceed 5s., and for each subsequent

visit in the same illness 2s. 6d. The midwifery fee, including subsequent visits that may be necessary, is £1. It is pointed out that the fees will be the same whatever be the distance of the patient from the doctor's place of residence. It is the duty of the Board to ensure the doctor further compensation for his services out of the parliamentary grant. Where medicines are supplied by practitioners an additional moderate charge will be made, but where not the patients must themselves pay the chemists' charges. Persons desiring to participate in the benefits of the scheme must be prepared to comply with all such reasonable requirements of the practitioner as will enable him to make the best arrangements for his patients. Messages must be sent early enough to reach the doctor before the hour on which he ordinarily begins to visit patients, and if sent later must state whether his attendance is urgently needed that day, or whether a visit on the following day would be sufficient. Where the practitioner is accustomed to make fixed visits on certain specified days to particular localities, all calls for his services, except in urgent cases, should be reserved for those days. Where duly qualified district nurses are available, it is directed that special calls for the services of the doctor outside ordinary visiting hours to patients living at a distance should be made through the nurses wherever practicable. In the relatively few cases in which two or more practitioners practise in the same area, the patient is given the right to select the practitioner he desires, but it is added that urgent calls should, as a rule, be sent to the nearest available practitioner. Practitioners called to cases outside the area in which they have undertaken with the Board to give attendance may charge their ordinary visiting fees, and agreements between the Board and practitioners do not interfere with any private arrangements in existence between practitioners and their patients whereby the latter receive attendance under a system of annual payments for each individual or family. The concluding clause of the notice is printed in large type, and is to the following effect: "If it is proved to the satisfaction of the Board that the privilege of a medical service at modified fees is misused in any district or by any individual, the Board reserve the right to withdraw the service from any such district or individual. In such cases the practitioner's ordinary fee will be payable." The offices of the Board are at 4a, St. Andrew Square, Edinburgh.

Ireland.

The guardians of certain unions in Ireland have found that considerable economies can be made by revising the dietary scale in the workhouses, which was drawn up sixteen years ago. The Roscommon guardians have recently decided to obtain copies of revised scales and to consult the Local Government Board as to the selection of the most suitable.

The first annual meeting has been held of the Temple Hill Auxiliary Hospital, near Dublin, which receives convalescent wounded soldiers and sailors. The house was offered by Mr. Hubert Power of Waterford and approved by the War Office for the accommodation of twenty convalescents, provided that the committee could show that it had in hand the sum of £1,200, which was at the rate of £60 a bed for maintenance for one year. The British Red Cross Society offered to contribute £300 if the local committee could raise £900. Generous support was received from individuals and from collections in parishes and church congregations. The work of the hospital has been carried on in the most efficient manner.

Alderman Dr. J. J. O'Sullivan, to whom his professional colleagues in Waterford recently made a presentation in recognition of his services in connexion with the settlement of the medical certification question under the Insurance Act, has been elected Mayor for the city of Waterford for 1916. It is very rarely a member of the medical profession in Ireland is selected to occupy the position of mayor, and it is all the more pleasing, in the present instance, to the Irish profession, as Dr. O'Sullivan has been in his professional and public capacity a consistent champion of his profession.

England and Wales.

At the winter conference of the Charity Organization Society and kindred bodies, held last week in London, General Sir Neville Lyttelton, Governor of Chelsea Hospital, said that it was estimated that between 13,000 and 14,000 soldiers and sailors had been discharged since the war began; many of them had already been absorbed into the ordinary work of industrial life, and with the exception of those seriously injured, no difficulty had as yet arisen in providing work. But the longer the war dragged on the greater would be the number of men discharged unable to follow their ordinary civilian occupations, and the problem would become one difficult of solution. Earl Fortescue described what had been and still could be done by placing men on small farms.

In November, 1914, an emergency surgical aid corps was established in London with head quarters at the house of the Royal Society of Medicine. Sir Rickman Godlee, the chairman of the executive committee, reported to a recent meeting that the corps had accepted two distinct duties: first, that of arranging for assistance in the case of raids of any description on the east coast from Dover to the Wash, and, secondly, that of organizing similar help in the case of aerial raids on the metropolis. Its offers of service were cordially accepted by the War Office, and two divisions of the corps were formed, one for the east coast and the other for London. Boxes containing first-aid dressings were stored at No. 1, Wimpole Street, and a night watchman was engaged; 155 gentlemen volunteered to serve, but for various reasons, chiefly the acceptance of commissions in the naval or military forces, their number at the end of the year was reduced to 107. Altogether nine calls were received, but, except on one occasion in London, the services of the members of the corps were not eventually required. Nevertheless, in view of the opinions of the Chief Commissioner of the Metropolitan Police and of the War Office, it was decided to continue the corps on the same footing. The necessary expenses have been met by voluntary subscriptions from members of the corps; the chief expenditure was in respect of the night watchman.

Correspondence.

RETIRED MEDICAL MEN AND MILITARY SERVICE.

SIR,—I have recently received several letters from senior medical men who have retired from serving in the Indian Medical Service, the Colonies, etc., and who lament that at present no place can be found for them in the national services of the sick and wounded of our navy and army. These gentlemen have mostly occupied high positions; they possess great experience in medical and surgical diseases and injuries, and, although they have retired, still enjoy an amount of health and energy which might be placed at the disposal of the nation.

From the most patriotic and laudable of motives, they chafe under the restrictions which prevent them from devoting their energies to the service of the country in connexion with the navy and army, while they naturally feel that these would be wasted were they, after the prominent positions which they have occupied and the exceptional experience which they have acquired, to adopt the only course which is available to them at present—that, namely, of offering to relieve general practitioners and panel doctors who have left to serve in the Royal Army Medical Corps.

It may be asked: Why do they not apply to the Central Medical War Committee, who are conferring on such subjects with the Director-General of the Army Medical Service? To this I would answer: That is the proper course to take, but not until it has been ascertained in what numbers and in what capacities these highly trained men are prepared to serve. Were this made certain, and were it evident that a considerable and valuable contingent were at the disposal of the nation, then the Central Medical War Committee should be approached, in order that it might confer with the heads of the Navy and Army Medical Services, so as to discover in what manner and

to what extent it could be utilized, either now, or when coming events may have increased the strain on the physicians and surgeons of the country.

If any of those interested in this subject will communicate with me, I shall be glad to have their suggestions, and perhaps arrange to have a meeting called should the response to this letter seem to warrant it.—I am, etc.,

ALEX. OGSTON,

President of the British Medical Association.

252, Union Street, Aberdeen,
January 30th, 1916.

THE SOLDIER'S "IRRITABLE HEART."

SIR,—I have read with great interest the valuable contributions to the etiology and treatment of this important condition which appeared in the *JOURNAL* of January 22nd. The causation of "irritable heart" is undoubtedly complex, but I was surprised to discover only one reference—casually by Dr. Poynton—to a cause which I am convinced is largely responsible, in combination no doubt in most cases with other causes, for disordered cardiac action, namely, tobacco. That tobacco smoked to excess—more especially the cigarette—is competent to upset the heart is a well recognized fact. I have had personal experience of the effect of smoking too many strong Burma cheroots. Intermittent action, palpitation and excitability of heart, breathlessness, anorexia, giddiness and general slackness were the principal symptoms. Probably hard work in the trying climate of Calcutta contributed to the development of these indications. They disappeared with a more moderate use of milder tobacco, and have not recurred. That the heart was not organically or permanently damaged is proved by the fact that, at the age of 75, I am able to negotiate a fairly stiff incline on my bicycle without palpitation or breathlessness. That soldiers in this war smoke to excess is, I think, unquestionable; and in the treatment of "irritable heart" the limitation of pipe and cigarette smoking should, I submit, constitute a leading item.—I am, etc.,

Westend, Hants, Jan. 25th.

KENNETH MACLEOD.

THE DIAGNOSIS OF FUNCTIONAL HEART DISEASE IN THE RECRUIT.

SIR,—Even at this, which might be termed the eleventh, hour in the medical examination of recruits, I am convinced that the haziest notions are prevalent amongst medical men in the diagnosis of functional heart disease.

In spite of the writings of Sir James Mackenzie and others, the examiner of recruits is frequently undecided in coming to a conclusion regarding a particular case, more especially when the recruit brings a note from his doctor which states that the bearer has tachycardia, heart weakness, or arrhythmia, rendering him totally incapable for military service.

The following simple rules I have found most useful, and I hope will be useful to others:

1. *Medical History.*—Has the recruit had rheumatic fever, syphilis, or does he indulge to excess in alcohol?

What is his occupation, and if laborious, does he complain of any of the classical symptoms of cardiac deficiency? In other words, ascertain if his "field of cardiac response" is normal. Inquiries in this direction need only take a few seconds. The question of anaemia with haemic murmurs does not obtain in examining recruits, as they are practically confined to women. If the recruit's medical history is above suspicion, a glance at the apex beat and application of the stethoscope at the various regions of the heart at once proclaim the healthy heart.

2. *Physical Examination.*—Having obtained a suspicious medical history, noticed a misplaced apex beat, or heard a murmur, I would advise a systematic examination, which only takes a few minutes, when done in the following manner:

(a) Note apex beat and rapidly percuss out left side of the heart. This should be the first and is the most important examination.

(b) Granted the apex beat and size of the heart as obtained from percussion are normal, it is almost certain there is no incapacitating heart disease, but to make doubly sure listen to the mitral area. An organic murmur heard there will be propagated to the axilla. A functional murmur is immediately lost to the left of the apex beat.

It may increase in intensity as it is traced inwards; and it always can be heard in the pulmonary area, where it is louder than at the apex. Compare the intensity of the murmur in these two areas by going immediately from the one to the other. If the murmur is louder in the pulmonary area than the mitral and is not propagated to the axilla, it is functional heart disease we have to deal with. An additional proof of a functional murmur, if one were needed, is that the second sound at the pulmonary area is only accentuated when we have organic mitral disease.—I am, etc.,

T. STEWART ALLAN ORR, M.B., Ch.B. Edin.,

Recruiting Surgeon,

Central London Recruiting Depot, Whitehall.

London, W.C., Feb. 1st.

THE SOLDIER'S HEART AND THE STRAINED HEART.

SIR,—In the genuine functional collapse of a physically overstrained heart the sudden onset may be regarded as a climax in a gradual exhaustion of the myocardium, and primarily as a myocardial failure. In the analogous functional heart-stroke induced in a nerve-worn subject by some overwhelming shock we may safely assume some degree of underlying myocardial inadequacy, but his disabling attack is primarily a nervous heart collapse. The soldier's heart might be regarded as a combination of both types. But in each sufferer the individual myocardial quality and the nerve quality are varying personal characteristics. That personal factor is the main difficulty in any attempted generalization as to differential diagnosis, prognosis, and treatment. There is great encouragement in Sir J. Mackenzie's favourable estimate of myocardial recuperativeness. But we cannot underrate Dr. Morison's misgivings as to the prospect of a complete restoration of the integrity of the nerve function. Neither should we underrate Dr. J. S. Manson's reminder as to the etiological importance of excessive smoking. I therefore regard total abstinence from tobacco as a first indication, though it need not be permanently enforced in those possessing a natural or acquired tobacco immunity.

It is comparatively easy to restore myocardial tone by rest and graduated exercise. The cure of the neurasthenia of the heart struck is much more difficult. Suggestion is probably its most powerful remedy. We are thoroughly justified by our uncertainty as to the nature and extent of the trouble in the individual patient in suggesting to him that there is no heart damage, but only the transient and curable effects of over-fatigue, and, perhaps, of too much tobacco.

As regards the significance in otherwise healthy subjects of occasional irregularity in cardiac action, and of occasional murmurs, I am in practical agreement with Sir J. Mackenzie. For some hearts an irregular gait seems to be the easier one under stress of external pressures. For others an imperfect systolic valvular closure may be the best compensation for any undue intraventricular pressure; but most frequently, perhaps, a harmless murmur, reputed mitral, is nothing more than a disguised reduplication, an overlapping of the normal but asynchronous first sounds. Mere loudness is not a reliable measure for the size of the leakage, if any should exist. As in whistling, the intensity of the sound varies directly with the degree of the pressure, and inversely with the diameter of the lumen.—I am, etc.,

London, W., Jan. 30th.

WILLIAM EWART.

DYSTOCIA DUE TO CONSTRICTED OS.

SIR,—Amongst the memoranda in the *JOURNAL* of January 29th, Drs. Owen Jones and Morris record an interesting case of a nulliparous woman who, they were informed, had previously suffered from procidentia uteri, which had been treated by ventrifixation, and had completely recurred. She then became pregnant for the first time, and, when she went into labour, delivery was delayed because the os externum did not open out.

But nulliparous women do not have procidentia uteri (the final or complete stage of prolapsus uteri). When they habitually wear the cervix outside the body, as the writers aptly put it, the condition is quite a different variety of genital prolapse. This begins with a developmental error, elongation of the cervix. The overgrowth of the cervix occurs at puberty, and often proceeds until the uterus is

5 in. in length. The os approaches and finally appears at the vaginal outlet; and, as it descends, the cervix pushes down the vaginal roof, and inverts it more or less from above downwards. The os externum in these cases is sometimes extremely small—the "pin-hole" os of the older writers. During labour the elongated cervix generally simply splits on one side or on both. Thus, from being a nullipara with a long cervix and a pin-hole os the patient becomes a parous woman with a long split cervix.

The diagnosis of this condition from prolapsus is easy, because in "long cervix" or "inversion of the vagina from above downwards," there is no cystocele. On telling the patient to bear down, the cervix emerges first from the vaginal outlet. In prolapsus uteri, when the patient bears down, the anterior vaginal wall appears first, being everted from below upwards, the bladder within it. Thus in prolapsus the cystocele appears first at the vulva and the cervix comes after it.

The treatment of the condition is to amputate the cervix so as to leave the uterus about 3 in. in length, and to repair the perineum if it has been stretched and thinned by prolonged pressure of the cervix and inverted vaginal walls. Ventrification is naturally quite ineffective for the treatment of "long cervix." Nor is it a good operation for cases of prolapsus. All varieties of genital prolapse are best treated by the vaginal and not by the abdominal route.—I am, etc.,

Manchester, Jan. 29th.

W. E. FOTHERGILL.

ENGLISH PUBLIC HEALTH ADMINISTRATION.

SIR,—My attention has just been called to the extremely encouraging review of my book under the above title in your issue of January 1st. I am indeed proud to have obtained such eulogy, but I must enter a plea of "not guilty" to the charge of making such a "reactionary suggestion" as that involved in urging that the public health administration should be divided between two departments, that of the M.O.H. and that of the sanitary inspector. On p. 107 I wrote:

The M.O.H. (in the larger districts) may be expected to be a man of considerable attainments and experience, and as such will realize the desirability of centralizing control over a staff having graduated responsibility in its separate departments. It is the method followed in all great business and industrial concerns; a responsible chief having subordinate departmental heads with wide discretion and ample powers.

and on the following page (108) I distinctly proclaim the M.O.H. to be "the natural and logical head of the service," and go on to opine that

It may, therefore, be expected, despite contrary tendencies, that sooner or later ordinary business principles will prevail, and that the public health departments will be organized in a series of sub-departments each with a chief responsible to and controlled by the M.O.H.

In the last paragraph of the chapter I outline a classification of sub-departments "with chiefs under the control of the medical officer of health," which I put forward as "suggestive rather than dogmatic."

I think this is ample evidence in support of my plea, and I trust that you will allow me the space to clear myself of the charge of making what I agree with your reviewer would be a "reactionary suggestion."—I am, etc.,

Upton Park, E., Jan. 29th.

B. G. BANNINGTON.

The Services.

EXCHANGES DESIRED.

CAPTAIN, R.A.M.C.(S.R.), Radiographer Casualty Clearing Station, is desirous of effecting an exchange to the base or to England. Address, No. 550, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Lieutenant, at present medical officer to a regiment in France desires to exchange with medical officer of a hospital, ambulance train or barge. Address No. 549, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.

THE American Association for Labour Legislation has initiated legislation to provide for the establishment in Massachusetts of a system of compulsory health insurance for all industrial workers earning 100 dollars (£20) a month or less. The insurance would cover any sickness, accident, or death not provided for under the head of workmen's compensation, and further benefits in the way of medical, surgical, and nursing attendance, medicines and surgical appliances, besides cash, maternity, and funeral allotments.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following degrees have been conferred:

B.M., B.Ch.—M. R. Lawrence, C. Dean, A. Traill, L. Gameson, A. G. East, G. T. Gimlette, L. M. P. Whitcombe.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

A SPECIAL introductory medical course in physics, chemistry, and biology for students desirous of beginning their medical studies will be held at University College, commencing on March 1st. Intending students should communicate forthwith with the Provost, University College, London (Gower Street, W.C.).

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

SECOND M.B., CH.B.—Part I: Hilda M. Brown, S. Datta, Marjorie S. Neville, T. H. A. Penniger.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—Part I, Chemistry; Part II, Physics: V. H. Barker, E. R. Boland, H. L. Bowen, E. Brazao, H. Dryerre, B. M. Gerson, W. Hardman, S. Hazeldene, J. W. Hulme, R. R. Jagger, A. A. Knapman, Margaret O. Meek, H. S. N. Menko, G. G. Newman, Madeline P. Parker, G. K. Reeves, B. R. Reynolds, H. N. Schapiro, G. F. Smith, W. Walsham, Octavia M. Wilberforce. Part III, Elementary Biology: V. H. Barker, J. B. Barnett, E. R. Boland, H. Brookman, H. S. Chadwick, S. H. Coplans, C. W. Empey, H. M. Gerson, Kate Glyn-Jones, J. B. Gregor, A. Hamid, E. Hardy, E. R. Jagger, M. A. R. Khalifa, A. A. Knapman, Margaret O. Meek, H. S. N. Menko, H. S. Morris, J. L. C. O'Flynn, E. A. I. Phillips, Betsy Porter, E. L. J. Reason, G. K. Reeves, I. Resnikoff, H. N. Schapiro. Part IV, Practical Pharmacy: R. Aspinall-Stivale, H. W. Barnes, E. G. P. Bousfield, C. V. Brainbridge, J. C. Collins, W. H. Dye, C. A. L. Evans, A. A. Fitch, F. J. Harvey, B. Haskins, J. F. Haynes, K. Masson, G. E. Mullins, V. A. Newton, B. Sahai, R. Sinha, V. R. Smith, G. C. Williams.

* Passed in Part I only.

† Passed in Part II only.

SECOND COLLEGE.—Anatomy and Physiology: R. W. C. Ball, G. A. E. Barnes, A. Blackstock, E. J. S. Bonnett, M. V. Boucaud, G. R. Cade, J. D. M. Cardell, T. Carlyle, N. Cheua, W. B. Christophersen, W. A. Clements, C. E. Cobb, A. I. Cox, H. C. Cox, C. K. Cullen, T. Davies, C. J. C. de Silva, F. B. Dutton, T. G. Evans, D. C. Farquharson, S. Finkelstein, J. B. Flamer-Caldera, C. A. R. Goonewardene, A. G. Hewer, C. L. Hewer, R. Hilliard, M. Jackson, J. W. Jones, S. Kadinsky, A. W. Lewis, S. S. Liebermann, A. D. Lokarathan, H. O. Long, A. V. Lopes, E. K. Macdonald, T. C. McKenzie, G. Millar, D. Mintzman, W. D. Nicol, E. Nissim, A. A. Osman, W. G. Owen, E. J. Papenfus, W. A. W. Parkes, A. L. S. Payne, E. A. Pearson, H. J. Perkins, J. Peter, E. F. Rabey, E. D. T. Roberts, J. S. Rogers, S. N. Senitzky, A. G. M. Severn, B. B. Sharp, B. L. Slater, S. R. Tattersall, C. J. Thomas, N. B. Thomas, R. A. Walker, A. D. Wall, A. E. Ward, P. E. Williams, S. A. Withers, S. Wolff, S. G. Woodhouse, V. D. Wyborn, C. Young.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMMITTEE was held on January 27th, Dr. Frederick Taylor, the President, being in the chair.

Admission of Members.

The following gentlemen, having passed the requisite examination, were admitted Members of the College: Aldo Castellani, M.D. Florence, and John Lloyd Davies, M.D. Lond., L.R.C.P.

Licences.

Licences to practise physic were granted to eighty gentlemen who had passed the necessary examinations.

Diplomas in Public Health.

Conjointly with the Royal College of Surgeons of England, Diplomas in Public Health were granted to the following candidates: Ratanjee Dinshaw Dalal, L.M. and S. Bombay; Philip Hamill, M.D. Cantab.; William John Hart, M.B. Oxon.; Horace Richard Wilson, M.D., B.S. Lond.

Duties of Medical Practitioners in Cases of Criminal Abortion.

A supplementary report was received and adopted from the Censors Board upon the duties of medical practitioners in relation to cases of criminal abortion (see p. 206).

Lectures.

The President announced that he had appointed Sir Thomas Barlow, Bt., K.C.V.O., to be the Harveian Orator for 1916, and Dr. Hector W. G. Mackenzie to be the Bradshaw Lecturer. Also that the Council had nominated Dr. W. J. Howarth Medical Officer to the City of London, to the Milroy Lectureship for 1917. After some further formal business the President dissolved the comitia.

Other Business.

On the recommendation of the Committee of Management, Sir Roger Manwood's Grammar School, Sandwich, and

Wellington College were recognized for instruction in chemistry and physics, and the Technical College, Swansea, in biology also. The committee also recommended that as the principle of recognizing the matriculation examination of a university without Latin had been adopted by the Royal Colleges in the case of the University of London in 1902, like recognition should be extended to the matriculation examinations of the universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham. Drs. F. J. Wethered, J. Calvert, J. Galloway, and C. Ogle were elected councillors, and Sir Francis Champneys re-elected the representative of the College on the Central Midwives Board. A resolution was adopted directing a letter of condolence to be addressed to Mrs. George Oliver on the death of her husband, who in 1904 founded and generously endowed the Oliver-Sharpey lecture.

Obituary.

JOHN WYLLIE, M.D., F.R.C.P.E., LL.D. EDIN.,

EMERITUS PROFESSOR OF MEDICINE AND CLINICAL MEDICINE IN
THE UNIVERSITY OF EDINBURGH.

By the death of John Wyllie, Emeritus Professor of Medicine and Clinical Medicine in the University of Edinburgh, which took place at his residence, 44, Charlotte Square, Edinburgh, early on the morning of January 25th, another notable figure has been removed from academic circles in the Scottish metropolis. In the Seventies of the past century there flourished a club known in Edinburgh as the "Round Table," a body remarkable for the high destiny of nearly all its members; the survivors of the nineteen or twenty members of these days now number only four or five, and they mourn the loss they have sustained in John Wyllie's decease. Edinburgh University drew largely upon the Round Table for its Professoriate, as the names of Sir Thomas Fraser, Crum Brown, William Rutherford, John Chiene, Alexander Dickson, and John Wyllie prove; and the extramural school had reason to be proud of many of the others, including Drs. Joseph Bell, Argyll Robertson, Angus Macdonald, Claud Muirhead, Charles E. Underhill, John Duncan, and Blair Cunynghame. Wyllie played his part nobly both in the extramural school and in the university, and did not fall behind any of his companions of the Table Round in the honour he brought to Alma Mater.

Born in Midlothian between Ratho and Gogar in 1844, sprung from a line of farmers, spending his early years at Bolton in East Lothian, educated at Edinburgh University in the early Sixties, and increasing his medical knowledge at Paris under Trousseau in 1866, Wyllie settled in Edinburgh in 1868. He had already made his mark with a gold medal for his M.D. thesis, with a double residentship (surgical and medical in the Edinburgh Royal Infirmary), with the senior presidentship of the Royal Medical Society (that sure index of the esteem and admiration of contemporaries in Edinburgh), and with two years as house-physician to the General Hospital, Birmingham; he had further fitted himself for the understanding of the view-point of the country practitioner by acting as a locumtenent once at least for Dr. Anderson of Selkirk. He was elected to the Fellowship of the Royal College of Physicians in 1870, and from that year he continued to teach until his retirement from the chair of medicine in the close of 1914. At first his subject was pathology (1870-78), then medicine (1878-82), then clinical medicine in the extramural wards of the Royal Infirmary (during his fifteen years' tenure of office there, 1882-97), then fevers at the Colinton City Hospital (1897-99), then clinical medicine in the university wards (in place of Professor Fraser, absent in India on the Plague Commission) in 1898-99; and, finally, on the death of Professor Sir Thomas Grainger Stewart, practice of physic in the university for fifteen years (1900-14).

But there was much more packed into these years than teaching, although it is perhaps as a teacher—a clear, concise, fully equipped, and stimulating teacher—that Professor Wyllie will be best remembered; and it was a fortunate thing that through his appointment as professor in the university he had again the wards of the Royal Infirmary thrown open to him for clinical teaching also. Yet there were important duties performed by Professor Wyllie outside of the hours devoted to teaching. Thus, for two years (1875-77) he acted as pathologist to the Royal Infirmary, and was succeeded in that office by the

late Professor D. J. Hamilton. For some six years he was a physician to the New Town Dispensary. For ten years (1878-88) he was honorary secretary to the Royal College of Physicians, and he discharged the duties of examiner in clinical medicine and in medicine for the university for a considerable number of years. Then there was the literary side of his achievement. Of the direction which this was to take an early indication was found in the subject he chose for his graduation thesis—namely, the physiology of the larynx—and he was never unfaithful to his first love. It is not surprising, therefore, to find him supplementing his winter series of lectures on practice of medicine by a summer course of instruction in laryngology and allied practical matters. Then, as time went on, he accumulated a vast amount of material bearing on the subject of the voice and its disorders and anomalies; and, finally, he began in 1891 to publish a long series of papers on the disorders of speech, a series which under that name appeared as a separate volume in 1894. These articles ran through three volumes of the *Edinburgh Medical Journal*, one being printed in almost every monthly part, and up to the very last one Dr. Wyllie retained the keen interest of his readers. It has sometimes been said that he was a man of one book; and whilst in a sense this is true (for his other contributions to medical literature had not the high note of distinction which his papers on the disorders of speech possessed), yet it must be added that it was a very great book, and left unsaid very little that was worth saying on the subject of the voice.

Professor Wyllie was emphatically a kindly man—kindly to his colleagues, to his students, to his patients, and to the younger doctors who used to consult him so often. The thoroughness he always exhibited with patients will be remembered; the notebook, the detailed questioning as to symptoms, the painstaking physical examination, the reasoned diagnosis and the sane prognosis, and the suggestive and rich therapeutics, were all of them incidents and features of consultations which were never without real and lasting benefit. The kindness was mixed with a trace of shyness and reserve, but when once this was broken down, as was always possible, by a well-chosen reference to his favourite study in medicine or to photography (his absorbing hobby) or to fishing (his loved recreation), no one spoke more brightly and attractively. He was perhaps at his best conversationally when he was led to describe his rambles through little-known parts of Europe with his camera and his fishing-rod. Yet it was not given to all who knew him to know him intimately, and to his shyness must in all probability be ascribed the degree of surprise which some of the profession felt when his election to the chair of medicine in the university was announced. Professor Wyllie never married.

The funeral, from Charlotte Square, Edinburgh, to Bolton in East Lothian (where Wyllie spent his childhood), took place on January 28th, and was largely attended by representatives of the University, of the Royal Infirmary, of the Royal Colleges of Physicians and Surgeons, and by many personal friends.

Sir JAMES AFFLECK, an old friend, writes: The death of Professor Wyllie means to many, and especially to those of his friends who have gone through professional life with him, a great cutting off. Dr. Wyllie's was a life devoted throughout with singleness of purpose to the cultivation of the science and art of medicine, with the view of making his acquirements available to those brought under his influence. For it was largely upon his work as a teacher that Dr. Wyllie's reputation rested. Gifted with the power of lucid exposition, happy expression, and apt illustration, his teaching, alike in the lecture room and the hospital wards, was of the kind to impress in an especial manner junior students, and to lay a sound foundation upon which their subsequent knowledge might be built. A large part of his time and strength was devoted to clinical teaching in the wards. An earnest student and worker himself, he demanded a high standard of diligent effort from his pupils, and slackness or irregularity in attendance would not be tolerated. As an examiner he was eminently fair and kindly, yet none knew better than he how to detect the man who had "ground up" for the occasion, and to deal with him accordingly. Living through a period which embraced the views and methods

of what might be termed the older and the newer medicine, he was able to appreciate and to utilize the good in both. It was a matter of regret among his friends that Dr. Wyllie did not write more, since few were better qualified than he to have enriched the literature of medicine; but he had an almost morbid shrinking from anything like display. His masterly work on the *Disorders of Speech* proved his high capacity as a thinker and writer, and will remain a worthy memorial of his powers. But it was not alone to the field of medicine that Dr. Wyllie's mental energies were restricted. He was truly one who "seeketh and intermeddeth with all wisdom." An omnivorous reader in history and in general literature, there were at the same time few branches of science that had not an interest for him. Big-brained and big-hearted, Dr. Wyllie had a wide outlook and a large human sympathy. His bright smile and genial and manly bearing were but the expression of qualities which won the affection of all who knew him. Those of the inner circle of his intimates and colleagues who sorrow most of all that they shall see his face no more will ever retain a sweet memory of his many virtues, and will rejoice and be thankful for the privilege of having been numbered among the friends of so singularly gifted and estimable a personality as John Wyllie.

Professor HUNTER STEWART writes: It was with sorrowfulness—not sadness—that the many friends of Professor John Wyllie paid the last tribute of respect to his memory on Friday last—sorrow, deep and poignant, that the influence of a spirit so lofty, so unselfish, so helpful to others had been withdrawn, and that they should see his face no more; but not sadness when they thought of the long life so worthily lived. Indeed, to his medical brethren who knew him well there was a feeling of honest pride that here was a man who had nobly continued the best traditions of the profession. John Wyllie's character and mental outlook was devoid of angularities; it rather seemed a rounded whole, developed symmetrically from within. Firm of purpose, he tested all new opinions by his robust common sense, and readily assimilated what his trained judgement approved. In social intercourse, perhaps specially at his own home, one saw him in other lights, and the sweetness of "Mary Morison" and the gentle flow of "Sweet Afton" were never sweeter or gentler than when sung by him. How delightful were the quiet evenings at his home when he talked on general literature which he knew so well! Nature in all its moods appealed to him, and keen fisher as he was, he has been known to stop for an hour on a beautiful stream, quite forgetful of the trout, "listening to the birds." As we laid his body to rest in the old churchyard of Bolton where his kindred sleep, within hearing of the murmur of the stream he loved so well, the sun broke from a wintry cloud, as if confirming the promise, "At evening time there shall be light."

Professor G. LOVELL GULLAND writes: One feels that in Professor Wyllie one has lost one of those personalities who cannot be replaced. He was a man of strong character and great individual force, with a definite conviction of his duty and mission, and a clear conception of the way in which he should perform them. His teaching was of prime importance in his life, and he took great pains with it, keeping in view the necessity of holding the balance between the presentation of recent thought and discovery, and the insistence on the unchanging principles which underlie the study and treatment of disease. He will never be surpassed as a teacher of junior students because of his power of giving a broad view, and at the same time insisting on the unvarying study of detail. As a physician he was sound, of ripe judgement, careful, and clear-sighted, while his kindness of thought and manner endeared him to patients and doctors. His old students all over the world will feel themselves the poorer for his loss, and his friends in Scotland will miss his help, his wisdom, and his thoughtfulness for others.

Dr. H. G. LANGWILL (Leith) writes: As a pupil in a very special sense of the late John Wyllie, and one who will remain a lifelong debtor to him, I should like to pay a small tribute of affectionate regard and esteem to my late teacher for his work in the treatment of stammering. It was in the early Eighties, on leaving school, where my

stammer had become steadily worse (doubtless as a result of the competitive viva voce conjugation of Greek verbs with their reduplications!) that I was brought to the notice of Wyllie, who was at that time working at the subject of stammering. The kindness, interest, and patience that he uniformly bestowed, not only on myself, but (as I saw later when a student in his wards) on any stammerer, made a deep and lasting impression. Stammering was then—and, alas! is yet—so little considered to be within the sphere of medicine that any one afflicted with it (and only those who have gone through it know in how wide a sense it is an affliction) could not fail to feel most deeply grateful to such a master in medicine, who lent his powerful aid to extricate the victim from a veritable "slough of despond." Looking back, the most striking feature, perhaps, was his extraordinary patience in trying to get his pupil to *understand and carry into practice* the lessons of his physiological alphabet. Our speaking is such an automatic performance that very few have any idea how difficult it is to get a pupil to *think* about the method of producing his words. Wyllie's patience was inexhaustible, and the characteristic little laugh with which he would greet the oft-repeated failures not only put the nervous patient at his ease (which is half the battle in treatment), but gave him the feeling that here was a teacher whom no stupidity would anger. His satisfaction, too—one might almost say personal delight—in devising effective illustrative sentences as exercises upon the various consonants was another characteristic trait, and one can almost still hear the rippling laugh which followed some favourite exercise, like "Tip-toe Tommy turned a Turk for tuppence."

SIR FRANCIS LOVELL, C.M.G.

We regret to announce the death of Sir Francis Henry Lovell, Dean of the London School of Tropical Medicine, which occurred at his house in Hampstead on January 28th. He was the eldest son of Henry Hill Lovell, D.C.L., of Apsley in Bedfordshire, and was born in 1844. He received his professional education at St. Bartholomew's Hospital, and obtained the diploma of M.R.C.S. in 1865 and that of L.S.A. in 1867. In 1873 he was appointed Colonial surgeon at Sierra Leone, and in 1878 was transferred to Mauritius where he became chief medical officer, president of the General Board of Health and a member of the Legislative Council. In 1893 he was appointed surgeon-general of Trinidad and Tobago and was a member of the Executive and Legislative Councils. He retired from the Colonial Service in 1901.

On his return to England he showed a keen interest in the work of the London School of Tropical Medicine, where his long official experience made him very useful. In 1901, when the number of students began to exceed the accommodation available for them, and it became evident that funds were urgently needed for the development of the school, Sir Francis Lovell offered to go on a mission to tropical centres for the purpose of enlisting the practical sympathy of public bodies and residents in the work. In pursuit of this object he visited Bombay, Calcutta, Ceylon, Singapore, the Straits Settlements, the Federated Malay States, Penang, Hong Kong, Japan, and Canada. Everywhere he received a sympathetic welcome from the administrative authorities, the leading members of the medical profession, and the principal merchants, native as well as British. He brought back with him a sum of nearly £10,000 and many promises of support in the form of subscriptions and further donations. He also obtained for the school the right in perpetuity of appointment to the office of Director of the Research Institute, then recently established by the Government of the Federated Malay States at Kuala Lumpur. In recognition of his services he was elected dean of the school. In 1909 he went on a second mission, again going to Ceylon and also to the West Indies. He visited Barbados, the Windward Islands, the Leeward Islands, Jamaica, Trinidad, and British Guiana. Once more he succeeded in making a large addition to the funds of the school whose interests he had so much at heart.

In 1893 he was made a C.M.G., and his name was included in the list of new knights in the New Year's honours of 1900. This was, we believe, the first instance in which a knighthood has been bestowed on a member of

the Colonial Service during his tenure of office. The event was regarded as unique in the medical history of Trinidad, and therefore as being a fit subject for special congratulation. An illuminated address, signed by representatives of the Medical Board of Trinidad and of the Trinidad and Tobago Branch of the British Medical Association, was presented to Sir Francis Lovell. It stated that the signatories recognized that the dignity had been worthily conferred as a reward of long and honourable service.

He was a representative of the Trinidad Branch from 1903 to 1905 and a member of the Colonial Committee.

In 1903 he became a Fellow of the Royal College of Surgeons of England. He was also an honorary LL.D.

Sir Francis Lovell, though modest and retiring, was a man of considerable force of character, and his influence on the work of the School of Tropical Medicine, though quietly and unobtrusively exerted, was none the less active and beneficial. His courtesy and kindness of manner made him everywhere popular, and, while endearing him to those who knew him well, contributed greatly to the success of his missions.

SIR GEORGE AUGUSTUS PILKINGTON, who died at Southport on January 28th in his 68th year, was the son of Mr. R. G. Coombe, surgeon, of Burnham, Essex. He received his medical education at Guy's Hospital, and took the diplomas of M.R.C.S. and L.S.A. in 1870. He was the first house-surgeon of the Southport Infirmary, being appointed in 1871, and retaining the position until 1875, when he engaged in private practice in the town. In that year he married the daughter of Mr. Pilkington of Blackburn, and at his father-in-law's request took that name. He continued to practise in Southport until 1885, in which year he was elected to represent the newly constituted Southport division in Parliament. He was defeated by the present Lord Curzon in 1886 and was re-elected in 1899, but not in the following year; his parliamentary career was thus short. He was twice mayor of Southport, and had been high sheriff of Lancashire. He received the honour of knighthood in 1893.

SIR HUGH OWEN, G.C.B., who was Secretary of the Local Government Board from 1882 to 1898, died at his residence at Highgate on January 28th at the age of 82. He joined the staff of the Board in 1876, so that he served through a period of transition in public health and Poor Law administration, on the course of which he exerted no little influence.

THE profession in Nottingham has sustained a serious loss by the sudden death of Dr. C. H. BROMHALL, at the early age of 36. While opening an abscess, on January 7th, he accidentally pricked his finger. This was followed by cellulitis of the arm and septicaemia. He died of heart failure on January 16th. He was educated at the Royal Lancaster Grammar School, and studied medicine at the Manchester University, where he took the degrees of M.B., Ch.B. in 1903. After serving as resident medical officer at the Birmingham Poor Law Infirmary, he held the posts of assistant house-surgeon at the Birmingham General Hospital, resident officer at the Birmingham Dispensary, and finally resident surgical officer at the Birmingham General Hospital for six months' temporary duty. In 1907 he was appointed resident medical officer to the Nottingham General Dispensary (Hyson Green Branch). Two and a half years later he commenced practice in the City of Nottingham. Being a man of great energy and considerable natural ability, he rapidly acquired a large practice. Living in the heart of a great industrial district, he had a very long list of insurance patients. He was also one of the district medical officers under the Nottingham Union. He was a shrewd and capable practitioner, and, although very hard-worked, did not lose touch with the more scientific aspects of progressive medicine. He was of military age and willing to do his duty, for he is known to have said that if selected for service by the local War Emergency Committee he should go.

By the death of Mr. JOHN HUMPHREY, M.R.C.S., which took place in London on January 27th, at the advanced age of 91, the medical profession loses one of its oldest

members. Mr. Humphry received his medical training at University College Hospital, and qualified in 1849. Thereafter he spent two years in the London Fever Hospital under Sir William Jenner, and was for five years medical officer at the Birmingham Union Infirmary. In 1855, during the Crimean war, he acted as civil surgeon, and was attached to the British Army Hospital at Renkioi, Asiatic Turkey, organized by the late Dr. Parkes, at whose special request he was sent out. In 1856 he was appointed medical superintendent of the Bucks County Asylum, Stone, Aylesbury, which had then been opened about four years; and here he spent the remainder of his long professional career, retiring about eight years ago. Throughout his connexion with the Bucks Asylum Mr. Humphry retained the confidence of successive visiting committees, and to mark his completion of fifty years as medical superintendent, in 1906, he received from the Visiting Committee, County Council, and residents in Buckinghamshire an illuminated address and service of plate. Mr. Humphry's administration of the Bucks Asylum was characterized by kindly consideration for the patients and staff, by all of whom he was beloved. At the same time he was always keenly interested in every advance in the treatment and care of the insane, and in his own institution carried out a policy marked by liberal ideas, and encouraged every effort to improve the nursing and treatment of the patients. He was a member of the Medico-Psychological Association for over fifty years, and also of the British Medical Association.

DR. SAMUEL ROBERT DUDLEY, who died recently at the age of 54, received his medical education at St. Bartholomew's Hospital and became L.S.A. in 1901 and L.M.S.S.A. six years later. He was gazetted a temporary lieutenant R.A.M.C. on November 23rd, 1915, and went to Canterbury on December 1st. He subsequently became ill and returned home to Ilford on December 18th and died on December 21st.

LIEUTENANT WALTER HALLIBURTON MACDONALD, R.A.M.C., died of appendicitis in Craigleith Hospital, Edinburgh, on January 22nd, aged 57. He was educated in the medical school of the Royal College of Surgeons, Edinburgh, where he took medals in chemistry and in medical jurisprudence, and also honours in anatomy, surgery, and midwifery; he obtained the Scottish triple qualification in 1889. He was appointed principal medical officer to the Imperial British East Africa Company in 1889, and when that chartered company's territories became a protectorate in 1895 continued to hold the same post. During his service in East Africa he gained the African war medal and clasp for Witu in 1890, a clasp for Mwele in 1895, the East and Central Africa Queen's medal with clasp for Uganda in 1897-98, the Africa general service King's medal with clasp for Uganda in 1900, and the Imperial British East Africa service medal in 1902. He received a letter of thanks from the Admiralty for service in the Mazumi rebellion in 1895, was present at the bombardment of Zanzibar, and received a sword of honour with the thanks of H.H. Sultan Hamoud in 1896, and the order of the Brilliant Star of Zanzibar in 1895. He was in medical charge of the Anglo-German Boundary Delimitation Commission of 1898, and was a corresponding member of the Royal Scottish Geographical Society. On the outbreak of the war he took a temporary commission in the R.A.M.C., was for some time stationed at Redford, and then, till his death, medical officer in charge of the troops of the Forth defences.

LIEUTENANT-COLONEL NICHOLAS LEADER, R.A.M.C.(ret.), died at Brentwood, Essex, on January 22nd, aged 63. He was born on April 15th, 1852, took the diplomas of L.R.C.P. and L.R.C.S. at Edinburgh in 1874, and that of F.R.C.S. Edin. in 1887. He entered the Royal Army Medical Corps as surgeon on February 3rd, 1878, becoming surgeon-major on February 3rd, 1890, and lieutenant-colonel on February 3rd, 1896. He retired on November 23rd, 1898, and joined the Reserve of Officers; he rejoined in the present war, and served until his health failed. He had seen much war service: Egypt, 1882, medal and Khedive's bronze star; Soudan, 1885, reconnaissance to Hasheen, actions at Hasheen and Tofrek, attack on convoy

on March 26th, and destruction of Tamai, two clasps; Chitral, 1895, with the relief force, medal with clasp; and the Nile expedition of 1898, when he was mentioned in dispatches, *London Gazette*, December 9th, 1898, and received both the British and the Khedive's medals.

DR. JAMES CLARKE WHITE, one of the most distinguished physicians of Boston, who died on January 6th, was born at Belfast, Maine, in 1833. He was educated at Harvard. After graduating M.D. in 1856 he studied dermatology at Vienna, and on his return to America acquired a great reputation as a dermatologist. From 1863 to 1866 he was editor of the *Boston Medical and Surgical Journal*, to which he continued to contribute till within a few weeks of his death. He was a man of considerable literary gifts and of the highest integrity.

MRS. GRANT, who with her husband, the Rev. A. C. Grant, went down in the *Persia*, was a daughter of Ex-Lord Provost Maitland of Aberdeen. As Miss Christian Davidson Maitland she graduated B.Sc. at Aberdeen in 1908, afterwards proceeding to Edinburgh, where she took the degrees of M.B., Ch.B. in 1911. After serving for a time on the staff of the Aberdeen Hospital for Sick Children, she went to India in 1912 as a medical missionary of the United Free Church, and worked in Rajputana, where she rendered valuable service. There she met Mr. Grant, a missionary, to whom she was married in Aberdeen last November. The young couple were returning to their sphere of duty in India when they met their tragic fate.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Meslier, formerly a representative of the Seine department in the Chamber of Deputies, aged 47; Dr. A. Millard, physician to the Beaujon Hospital, and for many years one of the leading clinical teachers in Paris, aged 85; and Dr. Thomas Miller, lecturer on anatomy and diseases of children in Howard University, Washington, aged 58.

Public Health

AND

POOR LAW MEDICAL SERVICES.

SCOTTISH POOR LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual meeting of the Scottish Poor Law Medical Officers' Association was held at St. Enoch's Hotel, Glasgow, on January 28th. The report for 1915 showed that during that year the number of vacant appointments was greater than usual owing to the fact that so many medical officers had accepted commissions in the Royal Army Medical Corps. Many of these vacancies had not been filled up owing to the scarcity of medical men eligible for civilian practice. It was pointed out that if many more medical officers were withdrawn from country districts a very serious question would arise as to how the medical necessities of the people were to be met. During the year serious friction took place between one parish council and its medical officer; ultimately the matter was settled by the resignation of the medical officer. In no case did the secretary require to warn applicants, as each one of the vacancies was quite legitimate. The Insurance Act appeared generally to have been of considerable benefit to the medical officers in outlying districts, particularly in the Highlands and Islands. The regulations of the Medical Service Board (Highlands and Islands), under which the medical officers would in future have to work, were issued in August last. A considerable amount of irritation was caused amongst some of the medical officers by certain of the regulations, which were considered to be too onerous, requiring a great deal of book-keeping, etc. The Board had tried to meet any reasonable objections, and it was hoped that the working of the regulations would not be so troublesome as some medical officers feared. The opinion was expressed that the Act must result in great benefit, not only to the general public, but also to the medical officers, in that portion of Scotland to which it applied. The death of Dr. Gilbert Campbell, who presided over the association for many years, was announced with deep regret. The financial statement presented by the treasurer, Dr. F. Stewart Campbell, 19, Westercraigs, Glasgow, showed a balance in hand. It was decided that this should be put into an Exchequer bond. The report was adopted. Dr. S. Prince Clark, Glasgow, was elected president.

Medical News.

PROFESSOR SHERRINGTON has been elected a foreign member of the Imperial Academy of Sciences, Petrograd.

At the meeting of the Liverpool Institution on January 27th a resolution was adopted congratulating Captain Noel G. Chavasse, R.A.M.C.(T.), 10th (Scottish) Battalion, King's Liverpool Regiment, on having received the Military Cross.

ON January 8th Surgeon-General William C. Gorgas was presented with the gold medal of the Geographical Society of Chicago. After the presentation he delivered an address on sanitation in its relation to geography.

ALDERMAN W. E. ST. L. FINNY, M.D., M.Ch., J.P., of Kingston-upon-Thames, has been called to the Bar at the Inner Temple.

THE many friends and old pupils of Sir Thomas Fraser will have seen with regret the announcement of the death of his son, Mr. H. C. Fraser, B.Sc., who was acting as a civil engineer at the Rosyth naval base. Sir Thomas Fraser lost another son in the navy earlier in the war.

SOME idea of the decrease in the production of medical books caused by the war may be gathered from the annual report of the library committee of the New York Academy of Medicine issued on January 1st. It is there stated that whereas 704 French and German publications were received during 1913, the number in 1915 was only 435.

ACCORDING to a telegram from Berne in the *Morning Post*, an appeal, signed by 246 German and Austrian scientists, has been made to the public not to cease to subscribe to scientific periodicals. Such periodicals, the memorialists state, are indispensable to scientific progress. Medical periodicals from Germany and Austria appear to have ceased to reach this country.

THE museum of the Royal College of Surgeons of England has been closed since June last, the motive being the desire to safeguard the collection from destruction during air raids. All spirit preparations and some of the more valuable of the others are now stowed in the basement, but those who desire to study any particular specimen will be permitted to do so. The conservator, Dr. Keith, is still in attendance, and anatomical and other scientific work is carried on in the workrooms of the college.

THE National Food Reform Association (178, St. Stephen's House, Westminster) held 450 demonstration-lectures and meetings for practical instructions in housekeeping during 1915. It is now arranging for about twenty demonstrations a week, and the experience of last year leads to the confident anticipation that they will be well attended by women of all classes—wage-earners, mistresses of small households, and social workers—who are anxious for lessons in economy with increased efficiency. An appeal for funds to carry on the work, both by way of demonstrations and leaflets, is signed by, among others, Sir Lauder Brunton, Dr. Robert Hutchison, and Professor Sims Woodhead.

AT the monthly meeting of the Medical Sickness and Accident Society on January 21st it was reported that the sickness claims for December were up to the expectation, though for the whole year they were below, notwithstanding the large sum paid to members invalidated home from active service. The proposals for increased sickness benefit from existing members continued to show good returns. The society still accepts officers of the R.A.M.C. for limited amounts in sickness benefit and life assurance without extra premium. It was resolved to form an investment reserve fund to meet the depreciation in stock values. Full particulars and forms of application can be obtained from the secretary, Medical Sickness and Accident Society, 300, High Holborn, London, W.C.

DR. SUZUKI, Fleet Surgeon in the Imperial Japanese Navy, after careful anatomical and microscopical researches, states (*Surgery, Gynaecology, and Obstetrics*, December, 1915) that the oxyuris may be harboured in the lumen and also in the mucosa and submucosa of the appendix without causing any symptoms or producing any noteworthy anatomical changes, but contends at the same time that there is a genuine appendicitis oxyurica. It is developed when the parasites have penetrated the wall of the appendix in large numbers, leaving a breach of tissue offering a portal of entry to the infecting agent. He met with one such case among 103 appendices removed by operation. In three other cases a non-inflammatory yet painful morbid condition of the appendix, accompanied by traumatic destruction of the tissue and evidence of hæmorrhage, were observed.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

PETROL DUTY.

G. R. P. has been informed that the local authorities have no instructions as to allowing a rebate in respect of the additional duty imposed by the Finance (No. 2) Act, 1915.

*. Section 10 (3) of the Act provides in clear terms that the old rebate shall be extended to the additional duty, and on due proof that the motor spirit used by "G. R. P." has been subjected to the full—that is, the present—rate of duty, his claim to a full rebate appears to be indisputable.

INCOME TAX.

PARTNERSHIP TAX inquires as to the effect of a dissolution of partnership on September 30th last.

*. Apart from any complication as to allowances by way of "abatement" or for life assurance, etc., the outgoing partner should pay one-quarter of the tax assessed for the year, and the remaining partner the balance, being one-half of the tax for the first half year and the tax for the second half year. The dissolution constitutes what the Income Tax Acts refer to as a "succession," and if the profits of the practice fall short for the second half year from any specific cause, such as the payment of an assistant or a diminution in the receipts, since or by reason of the succession, our correspondent will be entitled to an adjustment of the liability for the period from September 30th to April 5th.

INCOMPATIBILITY.

M., who has been in the habit of prescribing a mixture containing sodii salicyl. 3ij, potass. bicarb. 3iij, tinct. ferri mur. 3ij, aq. chlorof. 3viiij, asks whether the ingredients are, as he is told, incompatible.

*. The ingredients of the prescription are chemically incompatible, the iron reacting with both the salicylate and the potassium bicarbonate, and being precipitated as a substance consisting chiefly of ferric hydroxide. It seems probable, however, that the mixture is not affected very much physiologically by the chemical incompatibility, since the iron would be redissolved in the hydrochloric acid of the stomach contents, and would have as much effect as if it were administered in a soluble form in the first place. A little of the bicarbonate, and possibly of the salicylate, would be lost, but not a very large proportion of the quantities given in the prescription.

LETTERS, NOTES, ETC.

TEMPERATURE NECESSARY FOR THE DESTRUCTION OF LICE AND THEIR EGGS.

DR. J. PARLANE KINLOCH (University of Aberdeen) writes: I have read with much interest Mr. Bacot's paper, "The Temperature Necessary for the Destruction of Lice and their Eggs," which appeared in the JOURNAL of January 29th.

There does not seem to me to be any substantial difference between his results and mine when full account is taken of the different conditions under which the different sets of experiments were made.

I hope to be able to send you, in the course of a few weeks, a further contribution on the subject of insecticides, and perhaps it may be well that I should reserve till then such explanations as I may wish to offer regarding the apparent difference between Mr. Bacot's results and mine.

FOREIGN BODY IN THE RECTUM.

C. P. G. WAKELEY, M.R.C.S.Eng., I.R.C.P.Lond. (House-Surgeon, King's College Hospital), writes: A man, aged 43, came into hospital with the story that he had placed an egg-cup in his rectum to cure constipation, and was unable to dislodge it; he had taken 2oz. of castor oil the day before. The cup, concavity downward, could be felt on rectal examination tightly wedged between the tuberosities of the ischium. Part of the cup was broken, and the side walls of the rectum were slightly lacerated and bleeding, and there was a constant flow of liquid faeces. The egg-cup was acting as a ball-valve, and as soon as it was pushed up a little higher into the rectum

faeces escaped. Under an anaesthetic the external sphincter was dilated with the finger, but it was found impossible to remove the egg-cup as the lower part of the rectum and anal canal could not be dilated enough; an incision was made posteriorly dividing the external sphincter, when, with a little manipulation, the egg-cup was removed. The wound was packed with iodoform gauze, and a morphine suppository (½ grain) was placed in the rectum. The bowels were confined for four days, when they were opened by a dose of castor oil. The wound healed well, and the patient was discharged seven days after operation. I have seen the patient since; the wound has healed perfectly, and he states that he has complete control over his motions.

PHYSICIAN VERSUS SURGEON.

DR. JOHN HADDON (Hawick) writes: Since I published my book proving that food is the chief cause of disease, I watch with interest the contents of the medical papers, hoping to see that the physician is awakening to recognize the need there is to study the physiological action of our common foods. The ignorance upon that subject seems to me, since my eyes were opened, unpardonable; and the medical students of Scotland, at an inter-university congress, having unanimously passed a resolution that their teachers should be asked to teach them dietetics, have left the responsibility upon the medical authorities. All that is required is to make dietetics a compulsory subject for every licence to practise medicine, and it is to be hoped that the General Medical Council, which is responsible for the character of the education of medical students, will so far gratify the expressed desire of the medical students in Scotland. If I am right in my contention that food is the chief cause of disease, it is only by the study of the physiological action of foods that the physician can save his patients from falling a prey to the knife of the surgeon and having many of his organs removed which, through neglect, have become a danger to life. In this connexion I was pleased to notice T. A. R. Aiyar's experience as related in the JOURNAL of December 25th, 1915. He tells us of nine typical cases of appendicitis occurring in the natives of India, who object to submit to the surgeon's knife; and of the nine only one died, and it was a child, in whose perforated appendix an orange pip was found *post mortem*. There may be cases which only the surgeon can save, but there can be no doubt that appendicitis is a diet-produced disease, and from my experiments and observations on foods I believe it will be found that vegetables, by distending the caecum, lead to what is called appendicitis, although many perfectly healthy appendices are being removed by our leading surgeons.

Another communication, on epilepsy, by Dr. Pereira, in the JOURNAL of January 1st deserves special attention, for epilepsy, like appendicitis, is a diet-produced disease. Dr. Pereira has noticed that epileptic attacks depend upon meteorological states of the atmosphere as secondary causes. Hippocrates paid more attention to meteorology in connexion with disease than we do, but there can be no doubt that all who are in a plethoric state and suffering from anasarca, which the profession cannot yet recognize, are in danger of dying suddenly, as it is called, through some indiscretion in diet, or a sudden change in the weather. That accounts for certain diseases, and even abortion, occurring in runs, and being looked upon as epidemic.

A DOMINIONS YEAR BOOK.

THE *British Dominions Year Book* for 1916, issued by the general insurance company of that name, contains a series of articles bearing on the war in its various aspects. Thus there are articles by Sir L. Chiozza Money on a business-like empire; on the navy, by Mr. Jane; on finance, by Mr. Crammond and Mr. Keegan; and on the motor vehicle by Mr. Massac Buist. The last named has a very large subject, but endeavours, with much success, to deal with the general principles involved. One or two statements he makes are worthy of reproduction. He says that in the course of a single afternoon a batch of motor lorries may take forward 125 tons of shell and a million rounds of small arms ammunition. Speaking of the commissariat department, he says that motor meat safes, motor filters, and motor field kitchens are among the special varieties of vehicles furnished. Of the motor ambulance services, he says that the British is out and away the best. The book has a number of coloured illustrations which will help the civilian to understand the various badges and ribbons used by the navy and army.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

"TRENCH FEVER":

A RELAPSING FEVER OCCURRING WITH THE
BRITISH FORCES IN FRANCE.

BY

CAPTAIN J. W. MCNEE, M.D., R.A.M.C.,

AND

LIEUTENANT ARNOLD RENSHAW, M.D., R.A.M.C.

With the Clinical Assistance of

CAPTAIN E. H. BRUNT, M.B., R.A.M.C.

[Note by COLONEL SIR WILMOT HERKINGHAM.

DURING the whole time that the army has been in Flanders cases of short fever have continually occurred.

In a comparatively small number there has been a little bronchitis, or some diarrhoea, or tenderness of the muscles or nerves in limited situations. These have been called bronchitis, or influenza, enteritis, colitis, myalgia, and neuritis. But, as a rule, the symptoms have not included more than the general aches and pains which are the common denominator of all fevers. The patients have been very slightly ill, and except in a small number of cases have quickly returned to duty.

It has been very difficult to know what to call these cases. They have been sent in as influenza, myalgia, neuritis, pyrexia of unknown origin, and even as rheumatic fever. Of genuine rheumatic fever I have seen only five instances. Its absence has been one of the most striking things in the campaign, and effectually disposes of any connexion between this fever and wet or cold.

These undetermined fevers have from the first been the hunting ground of the bacteriologists, who with their laboratories are disposed in a line along the front, together with a few in special places further back. The bases have, of course, their own bacteriologists, and are not now under consideration.

The diagnosis of the enteric group of fevers is of such consequence to an army that the first task of the bacteriologist is always to exclude them. In consequence these cases of pyrexia have throughout been examined from that point of view. As they were usually seen quite early in the disease cultivation of the blood has been practised regularly, but cultivation of the excreta and agglutination tests have also been carried out in many hundreds of cases. In any case where either abdominal symptoms, or a dry tongue, or an enlarged spleen, or suspicious spots, gave clinical grounds for suspecting an enteric fever, the patient was sent down as "suspected typhoid" even if the bacteriological evidence was absent. But after all this had been done we were left with a large mass of cases in which neither the clinical nor the bacteriological evidence afforded any ground for this diagnosis.

In the early part of the summer Major J. H. P. Graham called my attention to a type of fever characterized by two bouts of pyrexia separated by a normal interval. He afterwards published two cases of the kind.¹ About the same time Captain Wells reported several similar cases. Colonel Sir William Leishman came round with me to see these cases. Their resemblance to sandfly fever and also to dengue struck those who had had experience in these fevers, but there were several points which effectually disproved identity. Other officers were good enough to look out for similar cases. I should like especially to thank Captain Stirling and Captain Bolus for their help. In the *Lancet* of November 20th, 1915, appeared a paper by Captain G. H. Hunt and Major A. C. Rankin, describing 30 cases and mentioning for the first time the name "trench fever," which by this time has come into common use. From these papers and from the paper now published I think we can say that from the mass of cases of obscure fevers one type has been isolated in which the clinical symptoms, the course, and to a certain extent the pathology, have been established. We are, however, still ignorant both of the nature of the infection and of the way in which it is introduced into the human system. It is still occurring, and this renders the agency of a flying insect improbable, though I was shown *A. maculipennis* only two days ago (January 29th).

The present paper needs no praise of mine, but I may

say that I have followed the work throughout with the deepest interest.]

The cases of the type to be described first began to be recognized in this laboratory area about the beginning of July, 1915, although, on considering the matter later, it was certain that a small number of men seen during the previous month had suffered from the same disease.

It will be of interest to give an account of how our attention was drawn to the condition in the first place. In the first few days of July a number of men, about twenty in all, were sent in to an isolation hospital labelled "suspected enteric." These men all belonged to a division which had recently arrived in the area, and all had headache and varying degrees of pyrexia, in addition to other symptoms to which less attention was paid at the time. Since it was known that during the previous two months cases of paratyphoid B had occurred both in the civilian population and in the division then in occupation of the area, it was at first thought that these new cases might be of the same nature. Blood cultures were made in bile salt broth in the usual way, and thereafter the cases were immediately transferred to a stationary hospital further from the front. These blood cultures proved one and all sterile. The men reached the stationary hospital within a week of the onset of the febrile symptoms, but, on admission there, their temperatures were either found normal or fell to normal within a day or two, leaving the patients apparently quite well. As the cases did not resemble clinically any of the enteric group, an inquiry was at once addressed to this laboratory to find out the results of the blood examinations. The bacteriological and clinical findings seemed to exclude the enteric group, although the possibility of previous inoculation modifying the course of genuine enteric had still to be considered at the time.

Cases of the same kind occurred immediately afterwards, and on these being watched it was found that the fever ceased after five to eight days. These men were examined carefully, and other symptoms recognized, which will be described in full later on. None of these early cases, however, remained under observation for long after the temperature fell to normal, so that their subsequent history is unknown. The point of this remark will be seen when the course of cases watched over a long period is considered.

As has been already indicated, all the early cases remained under suspicion of belonging in some sort of way to the enteric group. As more and more cases were observed, however, each with a similar and constant group of symptoms, the disease soon became recognizable as a definite clinical entity, and early became known to officers and men under the name "trench fever."

Since attention was attracted to the condition, great numbers of cases have come under our observation. During the months of July, August, and September, in fact, it was impossible to visit three or four field ambulances on any day without seeing at least half a dozen fresh cases.

During August and September arrangements were made, especially at one casualty clearing station, to keep a series of cases under constant observation for some weeks, and it is as a result of this that we have been able to carry out most of the clinical, pathological, and experimental work detailed below.

DISTRIBUTION OF THE DISEASE.

The cases have been met with, curiously enough, only among two classes of men—namely, those direct from the trenches, or at least from near the trench zone (artillerymen, etc.), and men of the Royal Army Medical Corps. On looking into our records no real exception can be found to the above generalization. Thus in our experience only those who have actually lived in or near the trenches and those who by reason of their work are constantly in contact with sick and wounded men from the firing line, have suffered from this disease. This seems important in searching for the means of transmission of the malady, and shows, at any rate, that the name "trench fever" is not without some justification.

No case has been met with in units such as ammunition columns, ordnance, head quarter troops, etc., which, although in the army area, are situated at some distance

from the lines. Of the Royal Army Medical Corps units, the personnel of both field ambulances and casualty clearing stations have suffered. No stationary or general hospitals being in the zone of the laboratory, we are unable to speak of them.

Age and service, foreign or otherwise, have had no influence, both old soldiers and newly joined men being

differ in their course, and that in a very curious and interesting way.

CLASS A.

The patient as a rule feels suddenly ill—headache, dizziness, and pain in the lower limbs being the most constant initial symptoms. Some men give a history of having been so suddenly overcome by headache and dizzi-

CHART 1.

CHART 2.

CHART 3.

CHART 1: This man was admitted on the fourth day of illness; a typical single relapse is shown. CHART 2 shows in part the tendency to remission often seen about the third day; the relapse is more gradual and prolonged than in the first chart.

equally involved. Officers and men too have apparently been affected in the same proportion.

It is important to observe also that in a casualty clearing station, where a room was specially set apart for the observation of such cases, four of the orderlies developed typical attacks of the disease. Other men affected in the same unit included the attendant of the incinerator, the man in charge of the Thresh disinfectant, an officer's cook, as well as other men on ordinary duty.

The question of the occurrence during the past summer of a similar disease among the civilian population has been gone into, and although it is difficult to get sufficient accurate information, it seems highly probable that such cases have existed.

In the course of inquiry some interesting particulars of the types of fevers found in the Flanders area have emerged, but no help has been gained with regard to a past history of this disease.

CHART 4. This chart shows a more irregular type of fever. The patient was admitted on the second day of illness. The symptoms continued until the eighth day, after which a relapse occurred on the twelfth day.

CHART 5.—This man had been slightly wounded in the shoulder, and came to the convalescent hospital with a normal temperature. The chart therefore begins on the first day of the attack. He had not been, when the illness commenced, in the ward where the other febrile cases were kept.

seated in the limb. It often gives rise to an intense feeling of restlessness, so that the patient is unable to keep his legs still for any length of time.

No diarrhoea is ever present, but, on the contrary, a tendency to constipation is frequently observed.

The fever varies in intensity, ranging up to 103° F. or 104° F. in the first day or two. The face is flushed, the

be confined to the "shins," but is often present in the thighs and behind the knees. It is difficult to say whether the pain is periosteal, or muscular, or both, but all the men state that it feels deep-

CHART 6.—It will be noticed that only a slight relapse occurred nine days after the temperature fell to normal on the eighth day.

CHARTS 7 and 8 are given as well-marked examples of the remission which may occur about the third and fourth days. Such a remission is well shown in two of the experimental cases.

TYPES OF FEVER.

Two types of fever will be described, and at first it was quite impossible to be sure whether both were varieties of the same disease or were two distinct entities. When the experimental work comes to be dealt with, however, evidence will be given which to our mind makes it practically certain that one disease alone is under consideration. Both types have identical symptoms, and the initial history of both is essentially the same. The cases only

eyes generally clear and bright, and free perspiration occurs. The tongue is furred, and there is great loss of appetite. No signs of catarrh are ever present in the chest. The pulse rate is only slightly raised, a common figure being about 100. Often about the third day there is a sudden drop of the temperature to normal or even subnormal, without abatement of the symptoms. Thereafter, however, the temperature rises at once, to fall again, in our experience, about the sixth to the eighth day. In

other cases, however, there is no such intermission, the temperature remaining continuously elevated for a week. When the temperature drops at the end of this period

• CHART 9.

not in all, is complicated by a single relapse. This is in contrast to the second type of case to be described, where the initial period of fever is not so long and relapses frequent. It seems as if, granting that the same disease is under discussion, a longer initial attack may give rise to only a single relapse, whereas a shorter period of fever at the beginning may be followed by several relapses. Enough evidence has not yet been accumulated to render this supposition certain, but we wish to suggest as additional evidence in favour of the disease being a single one that the duration of the malady with its relapses may be inversely proportional to the severity and duration of the initial attack.

The relapse is met with as a rule within four days of the temperature falling to normal. The fever is never very high, reaching perhaps 100° F. to 101° F. The duration is one or even two days, and during this period all the previous symptoms return, although with lessened severity.

CHART 10.—The above chart, from the case of an infantry officer, was the first case of the kind met with. Hence a great deal of attention was paid to it, and until subsequent similar charts became available, the nature of the illness remained a puzzle. Many examinations of the blood were made during and just before the attacks to see if any parasite could be found, but all proved negative. In the intervals between the pyrexial periods the patient was so well that he was out of doors all day; hence the interruptions in the chart shown by the dotted lines.

A series of nine charts, all from cases of the type described, are reproduced. It seems superfluous to give a clinical account of each example, so only points of special interest will be alluded to in the text.

CLASS B.

The chief distinction between this type and the first is the number and periodicity of the relapses, so that the disease takes on the characters of a true relapsing fever. This variety is less common than the first, only about twenty characteristic cases having been observed. Apparently, however, more have been seen so far in this than in any other zone of the British front.

This type of case begins with symptoms indistinguishable from the shorter illness already described. The headache, dizziness, pain in the legs, and tendency to

constipation, all are there, and there is high fever. In short, it is at this stage impossible to foretell into which class the case will fall. A point of importance, however, is that the initial fever does not last so long as in Class A. The duration of the initial rise of temperature is naturally the most difficult part of the disease about which to obtain accurate information, most of the cases having already passed through a field ambulance before coming under our observation. In cases seen from the very beginning, however (for example, two of the personnel of a field ambulance), the duration of the initial attack was about three days, and this bears out the story of other men who only came under observation later.

After the primary rise and fall of temperature the patient feels perfectly well, so well, indeed, that in several instances he has returned to his ordinary duties. Then, suddenly, after a varying number of days, the man is again aware that he is unwell. Headache is, as a rule, again the initial symptom, and is often accompanied by a sensation of cold, although no actual rigor has ever been observed. Pain in the legs and small of the back return with great

CHART 11.—This case was observed from the onset, the man affected being one of the personnel of a field ambulance. Note the short duration of the first febrile period, the temperature being subnormal on the morning of the third day.

severity, and on taking the temperature it is found to be high, often reaching 103.8° F. As a rule the onset of the attack is some time in the afternoon, and the height of the fever is reached the same evening. This relapse differs from that described under Class A in the following particulars:

(1) It is the first of a series of similar attacks; (2) it is sharper, the temperature is higher, and the symptoms are just as severe as in the initial attack.

The duration is short, the temperature rising quickly one day, to fall to normal, or almost normal, within the next thirty-six hours. Occasionally, however, the rise is not so rapid nor the fall so sudden, so that the relapse from start to finish covers a period of about three days (see Chart 13). The interval between the end of the initial attack and the onset of the first relapse is most frequently about four days, and once the relapse is over the patient returns again to a period of well-being.

With regard to subsequent relapses the periodicity varies, as is shown in the charts, the intervals never being exactly regular even in individual cases.

CHART 12.—This case was admitted to hospital suffering from scabies, and only fell ill after some days. The chart thus dates from the first day of the disease. On the twentieth day, when the third relapse was calculated to be due, the patient was given 20 grains of quinine. The effect was interesting, as, although the symptoms developed in marked degree, the temperature did not rise above 99° F. Q = Quinine sulph 20 grains.

The symptoms during the second and third relapses are, as has been already indicated for the first, of considerable severity, constant in character, and just as severe as in the

first days of the disease. In subsequent relapses, however, the symptoms are not so severe, nor does the temperature rise so high. It is the headache, however,

(c) there are the periodic short relapses—the most distinctive feature of all.

(5) *Malaria* and (6) *Relapsing Fever*.—These were both excluded by the absence of any parasite in the blood films or of any splenic enlargement.

PATHOLOGY OF THE DISEASE.

Work in connexion with the types of fever described has been carried on from various standpoints, and divides itself into bacteriological, pathological, and experimental. It may be said at once that the first two lines of investigation have yielded little information, but a brief account even of purely negative results must be given to complete as far as possible our knowledge

of the disease. From the experimental work, on the other hand, much important information has been gained.

Blood cultures have been made in a variety of ways. At first many of the cultures were made in the ordinary bile salt peptone broth used for the cultivation of the typhoid

which is chiefly mitigated, the pain in the shins remaining very troublesome.

It was interesting in these cases how often the men could accurately foretell the onset of a relapse, even before the temperature was raised. They "felt something coming on" in an indefinite sort of way, and later complained of slight headache. Thus sufficient time was often given to warn us at the laboratory that a case was relapsing, in order that various blood examinations could be made during the pyrexia.

DIFFERENTIAL DIAGNOSIS.

The chief diseases coming under consideration in this respect appear to be:

(1) *The Enteric Group*.—

This was excluded by (a) the numerous negative blood cultures; (b) the negative examinations of stools and urine; (c) the negative Widal reactions in the case of paratyphoid A and B; and (d) the periodicity of the relapses.

(2) *Malta Fever*.—This was excluded by the negative agglutination tests.

(3) *Dengue*.—The absence of any rash seems to rule this out.

(4) *Influenza*.—The differentiation from this disease is very important, because probably the majority of the cases came into hospital with a diagnosis of influenza. It is quite certain that a great

CHART 14.—This case is included as it shows a rather irregular type of chart. The man had taken ill a week prior to admission, with characteristic symptoms, and was presumably, when first seen by us, in his second period of fever.

group of organisms. This was done because at first, as has been indicated, nearly all the cases were suspected of being enteric fever owing to the pyrexia. It is sufficient to say here that at least 100 such blood cultures have been examined, all with negative result. All these cultures were made in the first few days of the disease, and this set of observations alone seems amply sufficient to exclude the idea first mooted that the disease might be enteric in reality, much modified by inoculation. The Widal reaction, so far as *B. typhosus* was concerned, gave no assistance,

CHART 15.—N = Normal.

CHART 16.

CHART 17.

CHARTS 15, 16, and 17.—These three charts all show the well-marked relapsing character of the fever. In each case the first attack had occurred before the case was admitted, the men only coming under observation on the seventh, fourth, and sixth days after the onset of the illness.

many will go down permanently into army records under that name. Influenza is excluded by the following points: (a) Absence of all catarrhal symptoms in the chest; (b) there is not the same prostration, cases often being found walking about with high temperatures;

owing to the high rate of inoculation. At one period a search was made for a case of the disease in an uninoculated man, but no such case on which to make agglutination tests could be found. Agglutination tests with *B. paratyphosus* A and B, and with *Micrococcus melitensis* and

paramelitensis, were made towards the end of some cases both of long and short type, but being always found negative were not persisted with.

A considerable number of blood cultures were also made using ordinary bouillon as the culture medium, again with negative results even when the culture was left for a week or longer at 37° C. More recently anaerobic shake cultures of the blood in a large volume of glucose agar have been tried, without success.

The faeces and urine have been searched culturally in a number of cases, both during and at the end of the pyrexia, but no abnormal organisms were found.

Blood films have been thoroughly searched, both in the short and especially in the relapsing cases, for the presence of any parasite, whether intracellular or extracellular. In a few instances the blood has been examined daily during the fever and between the febrile attacks, but nothing resembling a parasite has so far been discovered. Various stains have been employed, but especially Leishman, Jenner, and Giemsa, films being even left in the last stain for a period of several days. Fresh films of blood from some typical cases have been searched under dark-ground illumination, but no unusual appearance was detected.

The morphological changes seen in films are of some interest. As regards the red cells, only one pathological feature occurred with any degree of frequency. This was the presence of polychromatophil cells above the normal in size; and also, especially in the relapsing cases, of well-marked punctate basophilia. In several cases this latter change was so well marked that very careful examinations were made to make sure the appearance was not really due to an intracellular parasite. An explanation of these morphological changes was found when blood counts came to be made, as all the men examined showed a definite defect in the percentage of haemoglobin, the average colour index of a series of cases being 0.8.

Although the defect in the percentage of haemoglobin was constant, there was no loss in the number of red corpuscles, as will be seen from the table.

The leucocytes showed no morphological changes, and differential counts only indicated a slight relative increase in lymphocytes (large and small), with a rather low figure of hyaline cells. The details are given in full in the table.

EXPERIMENTAL WORK.

The experimental work was undertaken to satisfy any or all of the following questions:

1. Is the disease transmissible by the blood (a) to animals, (b) to man? If so,
2. What part of the blood is infective—the fluid or the cellular elements?

CHART 18.

CHART 19.

CHARTS 18 and 19.—The above two charts show types of fever different in their course from any of the others described. The clinical symptoms were, however, typical enough.

3. Can the disease be transmitted by any or all of the following: (a) Whole blood, (b) plasma, (c) serum, (d) corpuscles?

4. If the virus is transmissible, is it a "filter passer" or not?

5. If ultramicroscopic, is the virus in the fluid part or only in the cellular elements of the blood?

6. If a virus be proved, what is the method of transmission in nature?

Following out this scheme, experiments were first made by injecting the separated serum from marked cases into animals, rats and rabbits being used. Later whole blood (citrate) was tried, but none of the animal experiments bore any fruit.

Thereafter, with the approval of the authorities, it was resolved to extend the experiments to men who would

CHART 21.—Private W.

volunteer for inoculation. The experiments made in this way have been carried out in a casualty clearing station which by reason of its special situation has, during the past summer, acted as a convalescent station. Until special arrangements were made, however, no case could by rule be kept in this hospital for longer than a week, a fact which, as subsequent events proved, militated against the success of the first experiments. The men from whom volunteers were selected were almost all cases of minor injuries (sprained ankles, etc.), that is, men who although unfit to return to the trenches for some weeks were otherwise healthy.

The cases from which blood was taken for transmission were carefully chosen, only those in which no sign or history of past disease could be found being used. A number of typical cases were passed over at the time for this reason.

The experiments were begun on August 11th, 1915, when 5 c.cm. of blood were taken from each of two typical cases, and transferred immediately into the veins of two other men. Nothing occurred during the week these men remained under observation, and the men were then evacuated to the base and lost sight of. Positive results began to be obtained when permission was received to keep the cases, and the men inoculated from them, for a longer time under observation.

An account will now be given in detail of the first case in which the transmission was accomplished:

Transmission by Whole Blood.

On September 2nd an R.A.M.C. orderly, Private S., who had been on duty in the ward in which the "trench fever" cases were being kept, was in the middle of a brisk and typical attack of the disease. His temperature chart is given below (Chart 20).

CHART 20.—Private S.

the inoculation. On the evenings of the third and fourth days his temperature reached 99° F., but he felt perfectly well at the time.

On the morning of September 11th he awoke at day break, feeling unwell. He had a slight headache, and his temperature at 6.45 a.m. was 99.2° F. He got up, but could not remain out of bed for longer than an hour, as the headache became more and more severe, and he felt cold and "shivery." He returned to bed at 9 a.m. and soon after was attacked by pain, chiefly in the thighs and small of the back. Unlike other cases, he had no pain below the knees. By evening he felt very ill, and at 6.30 p.m. his temperature was 103.8° F. and pulse 88. Next morning he was rather better, the pain being easier, although the headache remained severe. His temperature, too, had fallen, being 99.8° F. in the morning and 100° F. at night. On the third morning his temperature was normal, but the headache remained, and the pain did not entirely pass off. The same evening, however, he was perspiring profusely, and felt just as ill as on the first day of the attack. His temperature on this occasion was 100.8° F. The following morning there was again a slight remission, but only for a short time, and during the next few days he was

very ill, until the temperature reached normal once more on the seventh day after the onset (Chart 21).

Immediately the temperature became normal he felt comparatively well, and was able to sit up for a short time. His headache was completely relieved, but he still had slight pain in the thighs. Thereafter two definite relapses occurred, the one reaching its acme on September 19th and the other on September 23rd. During these relapses headache and pain in the thighs and back returned with considerable severity, without being, however, quite so severe as at the beginning. It will be observed from the chart that one relapse was at its height about four days after the temperature fell to normal on the seventh day, and that the other followed after a precisely similar interval.

Various symptoms, etc., of lesser bearing have been purposely omitted in the account of this case, so as to bring those of importance into prominence. It is sufficient merely to mention that anorexia and a definite tendency to constipation—both symptoms common to many febrile diseases—were present to a considerable degree.

The subsequent course of the case was towards complete recovery, but it is a noteworthy fact that whenever the temperature rose in the least degree above normal (as, for example, on October 15th, thirty-five days after the initial fever), the pain in the thighs returned with severity. This has been observed in other cases, the patients being able to tell that their temperature was a little high by the return of the pain.

Fairly numerous blood examinations, made on Private W. during his illness, are shown in the table already given.

It was resolved to try to carry on Private S.'s infection through Private W. to a third generation, but no opportunity for doing so occurred until September 19th, nine days after the beginning of Private W.'s attack.

Transmission by Whole Blood.

On this day 10 c.cm. of blood were taken from Private W. into a syringe previously washed out with citrate solution, and injected intravenously at once into Private D.

This man kept well until September 24th, five days after the inoculation, when a typical attack of the disease was again reproduced (Chart 22).

He took ill in the evening, feeling "shivery" and out of sorts. His temperature was found to be 99.8° F., and during the night intense headache and pain in the thighs developed. Next morning when seen he was very ill, complaining especially of pain behind the knee-joints, and at noon his temperature stood at 102.4° F. The following day his temperature was normal, and all the symptoms practically abated, so that he wished to get up. Thereafter, although a slight rise of temperature occurred on three successive evenings, he kept perfectly well until October 4th. During this interval of ten days he was able to go out of doors every day, and felt quite in his usual health. A relapse then occurred, all the original symptoms returning with even more severity than in the first attack. His temperature reached 103° F. on the 5th, and then fell, all symptoms and fever having passed off by October 7th. A period of well-being again followed, lasting until October 15th, when a further

CHART 22.—Private D.

relapse developed with the usual set of symptoms. These were not severe, the temperature only rising to 100° F., and next day the patient was better again.

It is important to observe that the highest temperatures recorded in the three attacks occurred on the seventh, seventeenth, and twenty-seventh days after the inoculation—that is, the interval between the height of each illness was exactly ten days. The periodicity in this case has, we also consider, a further importance in helping to establish the unity of the "short" and "long" types of disease described in the earlier part of this paper. The first case, Private S., represents in our original description a fairly typical "short" type. The second, Private W., seems merging into the other or "long" type; and the third, Private D., if the case had occurred naturally, would have been put without hesitation into the latter group. The results of the experiments just described, taken along with the identity of the clinical symptoms in every case, seem to constitute very strong links in the chain of evidence supporting the view that all are simply varieties of one and the same disease.

The next experiment to be referred to had its origin also in an R.A.M.C. orderly, who had also been in contact with a number of cases.

Transmission by Whole Blood.

This man, Private C., took ill on September 15th, with the by this time well-recognized symptoms. His chart is appended, and shows a fairly typical curve (Chart 23).

On September 19th, when his temperature was 102.4° F., 10 c.cm. of blood were transferred immediately into the veins of Sapper M. This man kept well until October 2nd, thirteen

CHART 23.—Private C.

days after the inoculation, when he suddenly felt dizzy, cold, and shivery while going down the long hospital stairs. He had no headache until the evening, when his temperature had risen to 102.6° F. (see Chart 24). Pain in the legs had come on previously (at 4 p.m.), and was at first worst round the hips. During the night the pain became more localized to the back of the knees and to both ankles, and felt, so he said, deep down in the bones. The symptoms continued until October 7th without remission, when they passed off quickly. A relapse occurred on October 10th, four days after the end of the first pyrexial period, and a second on October 13th, after a similar interval of four days. On neither occasion were the symptoms severe, the temperatures only reaching 99.2° F. and 99.8° respectively.

CHART 24.—Sapper M.

Having shown in these three men—Private W., Private D., and Sapper M.—that the disease in typical form could be transmitted from cases by immediate inoculation with "whole blood," it remained to continue work on the scheme outlined at the beginning of this section.

Filtered Serum.

Serum experiments had been begun early, as the blood from typical and suitable cases could be collected at different field ambulances, the serum separated in the laboratory, and thereafter injected into volunteers. The first experiment with the blood serum, made on August 20th, was a failure, but the two men were only under observation for about a week. The serum was in this experiment

passed through a Doulton filter candle without dilution before being injected. On August 22nd the pooled serum from four typical cases was, after the addition of an equal bulk of saline, passed through a Doulton filter, and injected

CHART 25.—Private B.

into two men. Nothing happened, although the men were kept for a fair time under observation. This attempt to prove whether the virus was a "filter passer," before the infectivity of the unfiltered serum was tried, seems to indicate rather a cart-before-the-horse procedure, but it was adopted at the time for the following reasons: It was thought from analogy, in the first place, that the virus might be somewhat of the same nature as those of yellow fever or sandfly fever, etc.; and also, the blood being at the time collected, often under difficult conditions, from field ambulances, the sterility of some of the samples might be in question. We felt safe, however, in injecting the serums after they had passed through the porcelain filter candle.

Two other men were again, on August 25th, inoculated with the pooled serum of three typical cases, the serum being previously filtered through a Doulton candle. A negative result was obtained. The same type of experiment was carried out on August 27th, the pooled serum of four typical cases being filtered as before. A negative result was again obtained.

It was then suggested to us by Sir William Leislman that our failure to get the virus through the filter was possibly due to the serum not being sufficiently diluted with saline, in none of the experiments so far described more than an equal volume of saline having been employed. In our subsequent filtration experiments, therefore, the serum was always diluted with ten volumes of saline.

These experiments now to be detailed were conducted under the best conditions in the casualty clearing station where so much of the work has been done, and were designed to satisfy several questions at once. They must, therefore, be described as separate experiences, leaving the conclusions to be drawn at the end.

On October 7th blood was withdrawn from Private B., on the day before his fifth attack of fever, and in the fourth week of his illness. 5 c.cm. of blood were taken into a syringe washed with citrate solution, and injected at once into Private D.—m. The remainder was allowed to clot, the serum separated, and divided into two parts, each of 3 c.cm. One of these parts was diluted with ten volumes of saline and rapidly filtered through a Berkefeld "V" filter. Thereafter the 3 c.cm. unfiltered serum were injected into Private T., and the filtered and diluted serum (now 30 c.cm. of fluid) was transferred intravenously to Private M. These two injections were made about four hours after the blood was withdrawn.

The chart of Private B. (Chart 25), from whom the blood was withdrawn, is reproduced. When admitted he gave a history of two previous attacks of fever, and four relapses, shown on Chart 25, occurred in hospital.

Private D.—m (Chart 26), into whose veins the "whole blood" was injected, began at once to run an irregular temperature, but without obvious symptoms until the evening of the eighth day. Then the usual symptoms of headache, pain in the back and legs, etc., appeared, and continued until the temperature fell to normal three days later. Thereafter three relapses occurred, each reaching its acme, as shown by the highest temperature recorded, five days after the previous one.

Private T. and Private M., who received respectively serum and serum after dilution and passage through a

filter kept perfectly well for four weeks under observation, their temperature charts not showing any deviation from the normal.

In this experiment, therefore, only the "whole blood"

CHART 26.—Private D—m.

was infective, no result being obtained with serum, filtered and unfiltered.

The next experiment had as its basis the case of Private D—m (Chart 26), just described, whose attack followed the injection of the blood of Private B. The blood was withdrawn on October 15th, when the temperature was 100.8° F., and the symptoms well marked. Private W—x was injected at once with 5 c.cm. of blood, taken into a syringe washed with citrate solution. The remainder of the blood was taken to the laboratory in two parts, one being citrated to prevent clotting and the other being allowed to coagulate. The citrated blood was centrifugalized at once, 8.5 c.cm. of plasma being thus obtained. The other part of the blood yielded after coagulation 10 c.cm. of serum. This was divided into two, 5 c.cm. being set aside, while the other portion was diluted with ten volumes of saline and filtered as before through a Berkefeld V candle. The total bulk of the diluted fluid was thus 50 c.cm. It must be pointed out

CHART 28.—Private O.

times with normal saline solution to completely free them from traces of plasma. The washed corpuscles corresponding to 5 c.cm. of blood were then taken, suspended in sufficient saline to make up to 5 c.cm., and injected intramuscularly into Lance-Corporal B—x. The remaining washed corpuscles (equivalent also to about 5 c.cm. of blood), were mixed in a bottle with fine sand and glass

beads, and shaken thoroughly so as to break up the corpuscles as far as possible. The mixture was then extracted with saline and the bright red haemoglobin tinted fluid passed through a Berkefeld V filter. The filtrate (16 c.cm. in bulk) was injected intramuscularly into Gunner S. This last part of the experiment, in which an attempt was made to break up as much as possible the corpuscular elements, was undertaken to see if possibly (a thing hitherto unheard of) the virus might be ultramicroscopic and a filter passer confined to the cellular elements of the blood.

Of the three men injected in this experiment, only one developed the disease—namely, Private A., into whom the citrated whole blood was injected intramuscularly. The incubation period was twenty-one days, and the attack, which was typical, is shown on the accompanying chart (Chart 31).

The other two men were watched for over a month, and they remained perfectly well.

CHART 29.—Private N.

The only positive result obtained from this experiment was, therefore, the fact that citrated whole blood is infective when inoculated intramuscularly as well as intravenously.

Plasma: Corpuscles.

The last experiment of our series had as its basis Private A. (Chart 31), who had been infected with the

here that when ready for injection, owing evidently to some fault in technique, both the plasma and the serum were considerably haemoglobin-tinted, that is, some red corpuscles had been damaged and the haemoglobin liberated. The importance of drawing attention to this will be realized when the results of the experiment are noted.

Private W—x (Chart 27), into whom the "whole blood" was transferred, developed, as is shown in the chart, an extremely typical attack, with the usual relapse and the customary symptoms. The incubation period was in his case seven days.

In the case of Private O. (Chart 28), into whom 8.5 c.cm. of plasma were injected, a quite characteristic positive result was obtained after a period of thirteen days, as is shown in the chart.

A positive inoculation also resulted on the ninth day after the introduction of 5 c.cm. of serum into the veins of Private N. (Chart 29), whose chart is also given.

Clinically, the illness caused by the introduction of the "whole blood" was much more severe than that brought about by inoculation with either serum or filtered serum, a fact well shown by comparing the three temperature charts.

The man, Private R., into whom the filtered serum was introduced, remained absolutely without symptoms, even when watched carefully for over a month, and his temperature taken night and morning.

sitrated whole blood of Private P., injected intramuscularly. On November 10th, when Private A. was in his first day of illness, and his temperature 102° F., some of his blood was withdrawn into sterile citrate solution. All of the citrated blood was taken back to the laboratory for the following reason: It will have been observed that in all the previous experiments the citrated whole blood was injected at once, whereas the remainder of the blood had to be taken to the laboratory for preparation. Thus two or three hours generally elapsed before the remaining injections could be made. It was resolved on this occasion to make all the inoculations at the same time, so as to exclude the possibility of the virus dying out in the intervening two or three hours. All the injections in this experiment were thus made at the

final washing the corpuscles were made up to 10 c.cm. with saline before injection.

For the remaining part of the experiment the corpuscles corresponding to about 10 c.cm. of blood were obtained by the centrifuge, and washed, as before, five times with normal saline. The solid corpuscles were then mixed with fine sand and pounded up thoroughly in a mortar. The mixture was extracted with saline, and the product filtered through a Berkefeld V filter as usual, the result being 22 c.cm. of a clear, deep crimson fluid.

The results of the inoculations in this experiment may now be given.

Private R., into whom the citrated whole blood was injected, took ill thirteen days after inoculation, and his chart is given. (Chart 32.)

CHART 30.—Private P.

CHART 31.—Private A.

same time, about three and a half hours after the blood was obtained.

In this, our last, experiment the following tests were made, all the inoculations being intramuscular:

1. Citrated whole blood, both as a control and for the reason referred to in the preceding paragraph.

Private P.—d, into whom the washed corpuscles of 5 c.cm. of blood were injected, took ill with the usual symptoms sixteen days after inoculation. (Chart 33.)

Neither of the other two men, into whom, respectively, 4.5 c.cm. of plasma after passage through a Berkefeld filter, and 22 c.cm. of haemoglobin-tinted fluid (obtained by breaking up corpuscles and filtering as described) were injected, fell ill in any way during the full month they were observed.

All the men who were voluntarily inoculated with the disease have returned to normal health. Communication has been maintained

CHART 32.—Private R.

2. Corpuscles freed from plasma by washing with saline.

3. Plasma filtered through a Berkefeld filter candle.

4. The filtered product of broken-up corpuscles previously washed with saline.

The technique of the preparation for the last three parts of the experiment must be briefly recounted. The plasma was obtained readily enough by prolonged centrifugalization, and was quite clear and free from haemolysis. After separating the plasma, the corpuscles corresponding to 5 c.cm. of blood were taken, and washed five times in saline. The corpuscles were always thoroughly mixed with the saline before centrifuging, and 10 c.cm. of normal saline were used for each washing. After the

with some of them, and the only complaint has been a slight return of pain in the legs when fatigued in a few cases.

Other experiments throwing some further light on the illness could have been attempted, but it had always to be

CHART 33.—Private P.—d.

remembered that soldiers were the subjects of the tests. An important point to settle, for instance, would have been the question of whether one attack of the disease conferred immunity or not against a second inoculation.

SUMMARY AND CONCLUSIONS.

1. The disease is a definite entity, and of infective nature, as is proved by its ready transmission from one person to another by the blood.

2. There are two clinical types of the disease: (a) A short fever of about a week's duration, followed frequently after a few days by a short single relapse; (b) a longer illness characterized above all by the number, sharpness, and periodicity of the relapses.

3. The symptoms of both types are clinically identical, the most constant and characteristic being headache, and pain in the legs and small of the back.

4. The two types described are, in our opinion, merely varieties of one and the same disease. In addition to the identity of symptoms, the experimental evidence for this is strong, a typical "short" variety having been shown capable of giving rise to a typical "long" one.

5. The incubation period varies, possibly with the dose of the infective virus introduced. The shortest incubation period in our experimental transmissions was six days, and the longest twenty-two days.

6. The disease is transmissible in every case by the whole blood, whether injected intravenously or intramuscularly.

7. The disease is not transmissible by the serum. In the one instance in which the serum proved infective, haemolysis of corpuscles had occurred before injection.

8. It follows as a corollary to the preceding statement that the virus is not a "filter passer" in the serum, as we thought from analogy that it might be. All our experiments with filtered serum were negative.

9. The plasma was infective in one experiment, but haemolysis of red cells had occurred, so that the plasma was haemoglobin-tinted. The filtered plasma in another test was not infective.

10. The above results seemed to point to the virus being contained within the blood corpuscles themselves, whether leucocytes or red cells.

11. Blood corpuscles, after washing five times in saline to remove the plasma, were still found to be infective. This further supports our view that the virus is intracorporeal.

12. Very many blood films at all stages of the disease have been examined without a parasite being detected. The blood has been examined fresh, under dark-ground illumination, and dried films have been stained in varying ways, without result.

13. Blood corpuscles were broken down, and the haemoglobin-tinted fluid passed through a filter in an attempt to prove the virus an ultra-microscopic one confined to the corpuscles. The fluid when injected, however, was not found to be infective.

14. The only constant morphological change in the blood is the presence of punctate basophilia. This was so marked in some cases as to require very careful investigation to differentiate it from an intracellular parasite. The blood counts, differential and ordinary, did not yield any important results.

15. As regards the means by which the disease is transmitted in nature we have as yet no evidence to offer. The fact that only two classes of men are affected—those from the trench zone and men of the Royal Army Medical Corps—is, however, suggestive. The disease is either contagious from man to man or, what seems much more likely, is carried by one of the common flies or parasites found in the trenches. During the past summer lice, mosquitos, midges, and flies of other kinds have all been common in the Flanders war zone.

We wish to express our thanks to all officers of the Royal Army Medical Corps who have helped so much in this investigation, and especially to Surgeon-General Porter, Colonel Sir William Leishman, Colonel Sir Wilmot Herringham, Lieutenant-Colonel W. P. Peake, Captain G. W. M. Andrew, and Captain Vick.

ANTENATAL CLINICS AND PREMATERNITY PRACTICE AT THE EDINBURGH ROYAL MATERNITY HOSPITAL IN THE YEARS 1909-1915.

By J. W. BALLANTYNE, M.D., F.R.C.P.E.,

PHYSICIAN, EDINBURGH ROYAL MATERNITY HOSPITAL; LECTURER ON MIDWIFERY AND GYNAECOLOGY, SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH, ETC.

(Continued from p. 192.)

Autumn Quarter, 1912.

THE prematernity cases in the autumn quarter of 1912 were more than usually interesting. In all, 36 women, of whom 7 were unmarried and the rest married, passed through the ward. In two instances only did the mothers leave the hospital undelivered, and in both of these cases the conditions for which they were admitted (vomiting and pyelitis) were relieved. One or two of the other patients went out for a time, but returned for their confinements. As in the preceding autumn (1911), and as in that of 1909, there was one maternal death (from acidosis in early pregnancy); the remaining 35 mothers all did well, although some of them were very ill at the time when they were admitted. The fate of the fetuses and infants was more varied; 17 were born alive, and were living at the time they left the hospital; 2 were alive but still *in utero* when their mothers went out; and 20 perished at different ages, 2 dying a few days after birth, 1 succumbing in labour, and 17 having died antenatally. Seventeen is a large number, but it was swollen to that size by the occurrence of a triplet abortion and by the incidence of at least seven other abortions.

As usual, the indications for the admission to the ward of these expectant mothers varied within wide limits. There were seven cases in which abortion occurred, but the premature termination of pregnancy differed as to its causation. In one of the seven the woman had had repeated miscarriages, and in this her twelfth pregnancy she aborted once more; she had twice given birth to twins. There was no evidence of specific disease in her. Another woman was admitted as probably suffering from tubal pregnancy, but an ordinary abortion occurred; two others aborted because of retroversion of the gravid uterus, and another because of hydramnios. In one case of inevitable abortion no cause at all could be assigned. The seventh case was the triplet pregnancy.

The patient was 35 years of age, and had had four full-time confinements, and a miscarriage at the third month in March of the same year (1912). Her last period was in June. About a week before her admission to the Maternity Hospital (September 17th) she began to bleed and had pain in the lower part of the abdomen, and the day before her admission these symptoms returned. (A puzzling fact about her condition was that the fundus uteri reached almost to the umbilicus, and yet her amenorrhoea was only about two and a half months' duration.) Three months later she expelled a macerated three months fetus; since the membranes were not expelled she was given chloroform and the uterus was explored, when two more fetuses were extracted, along with a commencing placenta and what appeared to be one chorion and one amnion. One of the three umbilical cords was inserted into the placental mass in a velamentous fashion.

Three patients were admitted on account of albuminuria and three because they had had eclamptic fits. One of the albuminuric patients gave birth to twins, one of whom was still born and could not be resuscitated; another expelled a fetus weighing 8 lb. 10 oz., which had been dead *in utero* for some days; and the third delivered herself of a premature infant weighing only 3 lb. 12 oz., which nevertheless survived and did well. In all these three patients the usual dietetic and medicinal treatment was administered, and none of them developed eclampsia. The other three patients all had fits before their admission, and they were all somewhat serious cases; but they got treatment in the prematernity ward for at least two days before labour came on. They all had the stomach washed out, and a large dose of solution of magnesium sulphate was left in it; and two of them had venesection and the intravenous transfusion of a solution of calcium chloride (30 grains to a pint in one and 15 grains in the other). The three mothers all recovered, but one of the infants

was dead-born and one of the other two died a few days after birth.

The other prematernity patients were admitted for the following conditions: Hyperemesis and sickness (3), pyelitis (2), accidents in pregnancy (2), contracted pelvis (2), convenience, for example, poverty (3), acidosis (1), chorea (1), recurrent fetal death in previous pregnancies (1), phthisis (1), myxoedema and dilated heart (1), pernicious anaemia (1), haemorrhage from placenta praevia (1), nervous breakdown (1), spurious pains (1), venereal disease (1), and expected difficult labour from large size of child (1). Two of these cases may be referred to more in detail on account of their special interest, for in one there was marked acidosis which proved fatal, and in the other there was grave chorea which was completely cured by calcium chloride.

Acidosis with Choreic Movements.

The patient was an unmarried girl, 17 years of age, who was about three and a half months advanced in her first pregnancy. The twitching movements had been noticed for two months and bilious vomiting had first occurred a month before her admission. For a fortnight she had been under medical observation, and during that time she had been taking arsenic and chloral hydrate and potassium bromide, but without appreciable effect. There was no past history of chorea, of urticaria, or of erythema circinatum. When admitted to hospital she was found to be suffering from choreic twitchings which affected both sides of the body; she vomited everything taken by the mouth, and she retched frequently, bringing up bile-stained fluid. With an enema a good action of the bowels was obtained. The stomach was washed out with sodium bicarbonate solution and a large dose of magnesium sulphate was left in. Since I had found that calcium chloride had a good effect upon another case of simple chorea gravidarum, I tried it in this case, but it had no apparent effect. The urine had a specific gravity of 1025, was acid in reaction, contained a trace of albumin, showed 5 grains of urea to the ounce, and revealed the presence of both acetone and diacetic acid in considerable amount. The choreic movements ceased, but the bilious vomiting continued. The stomach was washed out on several occasions with the soda solution, some of which was always left in, and an intravenous transfusion of one pint of sodium bicarbonate solution (60 grains to the pint) was given into the median basilic vein. Her pulse began to fail notwithstanding the injection of strychnine and other means of stimulation, and she died six days after admission to the ward.

Chorea Gravidarum.

The patient was an unmarried girl, 20 years old, about the fifth month of her first pregnancy. When 7 years old she had an attack of chorea following upon a fall, and lasting for ten months. It was a severe attack, and a second, also severe, came on with no apparent cause when she was 14; the latter lasted for three months. For three weeks before admission she had noticed twitching movements, but two weeks later these became worse; she had something resembling a fit, and immediately the chorea came to be of a most pronounced and aggravated type. The movements were most violent, her clothes being torn, and her body tossed about in all directions; she was unable to articulate, she bit her tongue when she tried to swallow, and she bruised herself in various places. On her admission to the Maternity Hospital it was found necessary to lay her on a mattress on the floor, as she rolled out of bed on account of the uncontrollable nature of her movements. She had only had a few minutes' sleep for some days. She was given a dose of chloral hydrate and potassium bromide by the rectum, but without effect. On the evening of her admission she was given chloroform, and the following procedures were carried out: 10 oz. of blood were drawn off by venesection; 12 oz. of a solution of calcium chloride (60 grains to the pint) were run into the vein; the stomach was washed out; and a large enema was given. This was followed up by rectal injections of calcium chloride (20 grains in 6 oz. of water) every four hours during the night. No other means of treatment were used. During the first part of the night she was restless, but during the second part she slept continuously for the first time for a week. The movements on the following day were not so uncontrollable; and the rectal injections were continued. On the next day she was able to swallow, the movements were much better, the bowels had moved well, and the calcium chloride was now given (in 15-grain doses) by the mouth every four hours. She was able to take nourishment. A day later she was found lying quite quietly on her mattress, but she became excited a little if looked at by strangers; soon after this she was put into a bed, there being no longer any risk of her falling out. From this point onwards her progress was steady and remarkable. She remained in the hospital for six weeks, partly because her circumstances there were better and partly that she might be under medical observation. An interesting series of observations were made during the time upon her tendon reflexes, and in the later part of her stay the calcium chloride was reduced to 15 grains thrice daily. She then returned to her home, where she remained for a little over two months, returning to the hospital for her confinement. She delivered herself easily of a healthy male child weighing 8½ lb., and both she and her

infant did well. There was not the slightest return of the chorea. The case was particularly interesting on account of the immediate and very satisfactory effect of the calcium chloride, for practically no other medicine (save an occasional dose of castor oil) was given.

This was just the kind of case in which in earlier years I should almost unhesitatingly have induced abortion. The stomach-washing may, of course, have had some good effect; but I can hardly doubt that the calcium chloride was the chief agent.

Several of the other patients treated in the prematernity ward in 1912 were of more than passing interest—for example, the cases of myxoedema, pernicious anaemia, pyelitis, and phthisis; but considerations of space forbid their presentation in detail. Suffice it to say that in each instance the mother did well, but one of the infants, that of the woman suffering from pernicious anaemia, was dead-born.

Autumn Quarter, 1913.

Thirty-two patients passed through the prematernity ward during the autumn quarter of 1913. As usual, there was a striking diversity amongst the causes for which they were sent into hospital. Four came in on account of false pains, and two for convenience (poverty, distance from home); to these no further reference need be made. Two patients came in suffering from hydramnios; in one the distension pain was extreme, but labour was not much delayed, there was no *post-partum* haemorrhage, and both mother and child (weight 8 lb. 2 oz.) did well; in the other labour came on at five and a half months, there were uniovular twins, the hydramnios (about two gallons) affected only the second twin, and the mother made a good recovery. There were two cases of threatened abortion, staved off by appropriate treatment, and there was a third case in which a retroversion of the gravid uterus was detected, the uterus was replaced and kept in place with a Hodge-Smith pessary, and the gestation continued. There was one inevitable abortion (due to a recent infection with syphilis). There were three instances of albuminuria; in all three cases, under dietetic and medicinal and other treatment (stomach washing in one), the mothers did well and the children survived. There was a striking difference in the weight of the infants, one weighing 5 lb. 4 oz., another 5 lb. 5 oz., and the other 8 lb. 6 oz. Another patient with albuminuria had gone on into eclampsia (six fits) before her admission to the prematernity ward; she was treated there for a fortnight, had no more fits, and then gave birth to a dead and macerated fetus; her recovery was complete. There were two cases (first pregnancies) in which it was feared that apical disease (Pott's disease) would seriously interfere with labour. In one of them the spinal disease was accompanied by sinuses, excision of the left hip had been performed, and the adduction of the thigh was very marked; but delivery was accomplished with less difficulty than had been anticipated (forceps being used). In the other case there was very marked kyphosis, but the outlet of the pelvis was not contracted, and with the help of forceps the labour was completed. In both cases the baby survived and did well; the infant's weight in the first was 8 lb. 4 oz., and 6 lb. 8 oz. in the second. There were two interesting cases in which labour was induced before term, not because of contraction of the pelvis, but because in former labours the child had perished on account of its large size. In each case the medical attendant sent the woman into hospital.

In the one woman, a 4-para, the three previous infants had perished; she was already eight months pregnant, and when I tried to push the head into the brim I failed, and had made up my mind to recommend Caesarean section at the full term. On the following day, however, I found the fetal head lying in the brim. Acting on Nature's hint, I induced labour, and succeeded in getting a living child born (weight 8 lb. 10 oz.). Mother and child both did well. The other woman was a 10-para, who had had several miscarriages, and seven full-time labours, all made extremely difficult by reason of the great size of the infant. On the present occasion labour was induced, and a living infant, weighing 8 lb. 10 oz., was born without instrumental aid.

Another patient, a 1-para, came in on account of pendulous abdomen; she rested in the prematernity ward for a few days, during which it was discovered that she also had a large child. Labour would probably have been induced, but her pains came on, and with great difficulty a living male child, weighing 9 lb. 7 oz., was extracted by forceps. Yet another case may be named here:

it was one in which a medical man sent in a woman who had had two difficult labours, in one of which the child perished during its extraction, and severe *post-partum* haemorrhage occurred; the cervix was torn, and the doctor thought that septic infection could be better safeguarded against in the hospital. At any rate, the result was satisfactory for both mother and infant. She was given calcium chloride during her stay.

There was also a woman admitted who was thus able to get several days' rest in the ward between the initial bleeding from placenta praevia and the labour. Both mother and infant did well.

It was certainly an advantage to have this patient under medical supervision, and aseptic precautions were thus facilitated. A patient with cystocele and another with prolapsus uteri were both benefited by a fortnight's rest in the ward before they went into labour. There was also a patient who was sent in supposed to be suffering from hyperemesis, but four days' stay in the ward served to show that it was a passing dyspepsia, and she went out well.

The remaining six patients all suffered from medical disorders—one from icterus gravidarum, one from gastric ulcer, one from chlorosis, one from marked anaemia, one from thromboses of the femoral veins, and one from sarcoma of the thigh. To take the last named first—the woman, whose age was 34, a 7-para, was sent in from Leith Hospital, where it was intended that she should have the left leg amputated for a large and rapidly growing sarcoma. Since the child was viable labour was induced and a living child born, and ten days later the mother was removed to Leith Hospital, where the amputation was carried out. The patient suffering from catarrhal jaundice also came from Leith Hospital. It was her fifth pregnancy. After a few days under appropriate treatment in the ward she went into labour and was delivered of a living child, weighing, however, only 4 lb. 3 oz. The fetal surface of the placenta and the umbilical cord were deeply bile-stained. On the fifth day of the puerperium the last trace of jaundice had disappeared, and the patient was able to go home on the tenth.

Chlorosis.

Another patient, 34 years of age, showed chlorosis in a marked form. She had had five previous pregnancies, and in the fifth she had suffered from anaemia, which caused pallor, dyspepsia, oedema of the feet, and breathlessness, and there had been albuminuria. She was now pregnant for the sixth time, and had arrived at the eighth month; she had the same symptoms as in the previous gestation; and the examination of blood films revealed the characters of chlorosis. There were anemic bruits and a considerable degree of cardiac dilatation, with pulsation in the neck. On the third day after admission she went into labour prematurely and gave birth to twins, the one weighing about 4 lb. and the other about 3 lb.; the smaller twin died three days later, but the other survived. The mother was kept in hospital for a month, and was given iron and arsenic in large doses; she was much better when she left the hospital.

Acute Anaemia.

Another patient suffered from a somewhat similar group of symptoms, due to acute anaemia (haemoglobin 40 per cent.), with breathlessness, and oedema of the whole body; she was in her ninth pregnancy, and had not suffered so seriously in any of the previous ones. She was put on digitalis and diuretin, and 13 oz. of fluid were withdrawn from the left pleural sac. Nine days after admission she gave birth prematurely to a male child weighing 5 lb., who lived for five days. During the puerperium strong measures had to be taken to keep her alive, and they were so far successful that at the end of fourteen days she went home, although I was willing and indeed anxious she should have stayed longer.

The two remaining cases—that of gastric ulcer and that of femoral thrombosis—both proved fatal, the latter during my term of service and the former under Sir Halliday Croom's care, towards the end of October.

Gastric Ulcer.

I need not enter into details regarding the patient suffering from the gastric ulcer, save to state that she had a number of very severe haematemeses both before and after her admission; she was much benefited by her stay in hospital and by the treatment she received (rectal feeding, etc.), and left, contrary to my advice, after a five weeks' stay. She returned in four days in a very serious state, having had vomiting and haematemesis following upon gross dietetic indiscretions. Slowly she was again brought back into a fair condition, and at the end of my quarter I left her almost as well as when she first went out. For a fortnight, as Sir Halliday Croom informed me, she continued satisfactory; and then the old symptoms returned, vomiting was continuous, making all feeding by the mouth impossible, and persisting even when rectal nourishment alone

was given. Consequently, as she was now near the full term, labour was induced. The uterus from the first acted very poorly, and the fetal heart ceased to beat; in the second stage she was much collapsed, so forceps was used to extract, but without success, and finally she was delivered by craniotomy, but she was then moribund.

Of the other fatal case a few details may be given:

Extensive Thrombosis.

The patient, an unmarried woman aged 36, was pregnant for the first time. She was admitted on account of pain in the left leg, and she was found to be suffering from thrombosis of the left femoral vein. Contrary to what one usually finds, rest in bed, supporting the limb in cotton-wool, the use of sedative lotions, and careful regulation of the bowels, failed to improve matters, and in a few days thrombotic changes began in the right leg also. She then rapidly became seriously ill, suffering markedly from abdominal distension and from pain lower in the legs. Induction of labour was begun by means of packing the cervix; but her pulse rapidly mounted to 120 and then to 136, and I decided to open the abdomen as a last resort and deliver by that route. With the co-operation of Dr. Fordyce I opened the abdomen, finding a greatly distended intestine, a thrombosed condition of all the pelvic veins and of some of those of the inferior mesenteric system, and a small perforation of the ileum. I opened the uterus and extracted a dead child (nearly 5 lb. in weight); then hysterectomy was performed, but the patient died before the abdomen was completely closed. I had never before seen so far advanced a case of thrombosis in pregnancy or in the puerperium.

The two cases just described were the only ones in which a maternal death had to be recorded, and the remaining 30 mothers all left the hospital well or much improved. Of the 34 babies (for twins occurred twice), the after-history of 4 is not known, for the mothers left the hospital before delivery; 21 survived and left the hospital well, and 9 died, 4 post-natally and 5 ante-natally or intranatally.

(To be continued.)

BRILLIANT-GREEN AS AN ANTISEPTIC.

BY

ARCHIBALD LEITCH, M.B.,

PATHOLOGIST TO THE CANCER HOSPITAL, LONDON;
CAPTAIN R.A.M.C.T.

Much doubt has been cast on the efficacy of the more commonly known antiseptics in the treatment of septic wounds in war surgery. Indeed, the doubt has gone so far that some surgeons have given up the use of antiseptics altogether in these circumstances and rely on physical measures entirely, partly because most antiseptics restrain the reparative action of tissues, and partly owing to an enthusiastic, if somewhat tardy, appreciation of the fact that the phenomena of inflammation are not wholly baleful. No one with any experience of the shell wounds with which we have to deal would rely solely on antiseptics for their treatment, neglecting the means of assisting the natural processes of defence against bacteria, nor, on the other hand, should one blind himself to the fact that these natural defences, even at the best, are defective. In the use of the older antiseptics, their good effect, as regards the bacteria that could be directly affected, had to be balanced against the harm they might do to the tissue cells and fluids concerned with the bacteria not susceptible to their localized action. Recognizing these drawbacks, the surgeon demands an antiseptic that is without harmful effect on tissue cells, that is an adjuvant and not a hindrance to the processes of repair. Certain endeavours, notably by the use of preparations of hypochlorous acid, have recently been made to this end, but much remains to be done before we attain the ideal antiseptic.

I have been pressed by several people who have become aware of my employment of a new antiseptic in France to give an account of our experiences with it. As the method is still in a more or less experimental stage, I can only speak in a general way about it, trusting that others who may be interested will assist towards its improvement.

A brief note by Drs. C. H. Browning and W. Gilmour¹ on the bactericidal properties of various aniline dyes first attracted attention to the possible use of such substances in clinical practice. One of the triphenylmethane compounds used by these workers in test-tube experiments—namely, brilliant-green—was shown to have a very marked bactericidal value; in such excessively weak concentra-

tions as 1 in 5 millions it inhibited the growth of staphylococci, whereas concentrations of 1 in 250,000 of mercury perchloride were required to effect the same result under identical conditions. I have repeated some of their test-tube experiments. No two sets of experiments by different workers, especially in such a matter as this, can be expected wholly to coincide, but the conclusions are in practical agreement. I found that brilliant-green in concentrations of 1 in 500,000 inhibited the growth of staphylococci and streptococci under conditions in which concentrations of mercury perchloride of 1 in 50,000 were required. With colon bacilli stronger concentrations were needed, but the proportion between the two bactericidal substances still held. The method used for the test—Professor Delépine's, I believe—is, of course, only one of several means of estimating the bactericidal properties of chemical substances, and different methods might give different, though not conflicting, results, but still one would be safe in saying that brilliant-green is five to ten times as powerful as mercury perchloride for our purposes.

Browning and Gilmour pointed out that the presence of serum greatly diminishes the bactericidal potency of perchloride solutions, but to a much less extent that of brilliant-green. This effect of serum holds with regard to many antiseptics, and is a most important point in practice, seeing that all wounds are serum-soaked. The potency of an antiseptic in the treatment of wounds is not therefore to be measured by the ordinary test-tube experiments. The practical results alone can give us an estimate of its value, and so many factors enter in that even a very lengthy experience can provide us only with a rough approximate of the relative values of different antiseptics. Fortunately, with brilliant-green we have evidences of its outstanding merit as compared with older antiseptics. Several other aniline dyes have undoubtedly high bactericidal values, and some of them are innocuous to tissue cells, and when it comes to trying them in clinical practice, as almost certainly will be the case, we shall then have the difficulties to face in assigning them their relative values.

I had the opportunity of trying brilliant-green in certain septic conditions previous to the outbreak of war, and was convinced that, in addition to its marked antiseptic property, it had no apparent harmful action on tissue cells; on the contrary, it seemed to stimulate strongly the formation of granulation tissue. These first impressions have been amply borne out by the experience gained in the treatment of wounds at one of the base hospitals by my colleagues and myself. They are probably more enthusiastic than I am myself about its virtues. What the proper strength of solutions should be can only be settled after many trials, but we have used it mostly in solutions of 1 in 1,000. Very often the ordinary tap water gives a precipitate, but this is certainly avoided by the use of distilled water. I have been accustomed to make the solutions in sterile distilled water, but this precaution is probably unnecessary. Generally we used normal saline solution, and the brilliant-green can be dissolved in hypertonic salt solution without fear of precipitation. The solution is a very dark green, slightly turbid sometimes when freshly prepared, but clearing up on standing. It stains the skin very readily, but the stains can be removed by spirit, and should be avoided altogether by the use of rubber gloves, and care has to be taken to avoid staining the bedclothes, though, as a matter of fact, the colour comes out in the washing.

The wound is cleaned out as far as possible by dry swabs and well syringed with saline solution, any foreign material, of course, being removed. With a syringe, then, we apply a small quantity of the brilliant-green solution, perhaps an ounce or so. The stain diffuses quickly over the whole surface of the wound, temporarily colouring everything a dark green. The wound is packed lightly with gauze swabs dipped in the solution, and covered with jaconet to prevent the dye spreading to the patient's clothing. I have not hesitated to plug deep wounds tightly with gauze so saturated, and experience under such circumstances has shown that free drainage is not so necessary as we have been taught to believe. I have removed foreign bodies, such as pieces of clothing, from recesses of wounds after the temperature and sepsis had subsided. Hitherto I have not tried the introduction of brilliant-green into closed septic cavities, such as wounds

of the knee-joint, owing to lack of opportunity and perhaps excess of caution. Once we had the opportunity of using it in a case of gonorrhoea, much to the patient's satisfaction.

Ordinary wounds were dressed once a day; very septic wounds twice daily for the first day or two, and then only once afterwards. The results, even after the first dressing, are very striking. The first thing we mark is the cessation of the foul smell. Almost invariably this is achieved as the result of one dressing. It is a very strong antiseptic so far as anaërobic organisms are concerned, and though the rôle of the anaërobic, that contaminate practically all the wounds we see, may not be very deadly, yet their subordinate effects are not negligible. When the first dressing is removed we see that only the skin and necrotic tissues are stained. Living tissues in the wound retain their normal colour. The fact that dead tissue is stained an intense green is a great advantage, as it enables us without any trouble to identify and remove it. Before the wound was first dressed it might be that there was a thin serous discharge with no really healthy reaction of the tissues—the tissues were stunned, as it were—but after one or two dressings the repair is evident. It may seem a strange thing to be glad to welcome, but the brilliant-green does at first encourage the formation of pus in such wounds, and we have learnt to appreciate what in our youthful ignorance we scoffed at, the desideratum of our grandfathers, "laudable pus." But this evidence of the natural defensive powers of the body, welcome though it is, does not outstay its strictly necessary time. It fairly quickly diminishes, and is at no time copious.

Another very striking feature is the rapidity with which good red granulations appear and progress. Undoubtedly the impression is accentuated by the contrast in colours between the adjacent skin and the granulation tissue—the green and the red; but, allowing for that, the tissue reaction is indeed well marked. It sometimes happens that after a few days the diminution of sepsis ceases to be progressive, and the granulations are paler and flabby. It seems, then, as if the brilliant-green had lost its virtue. Our enthusiasm is tempered. What is the cause of this arrest I have not yet determined; whether it be that the tissues are over-stimulated, or there has remained a strain of bacteria that have learnt to be resistant to the action of the dye, or the concentration of the substance is not suitable. In a few cases in which I made cultivations I found practically pure cultures of long-chained streptococci that grew very sparsely, whereas previously the growth had been very mixed and very abundant. When we came across such a condition of arrest we found that if we changed our treatment the healing process was resumed, and our main stand-by was iodine water. Doubtless many other antiseptics would get over the difficulty. Other aniline dyes such as crystal violet have been shown to be strongly bactericidal, and are probably innocuous to tissue cells, and might usefully be employed to supplement the action of brilliant-green.

The results though striking are not marvellous. Some cases are disappointing in that we have not to evacuate them to England with the sepsis still going on, but these cases have resisted all other modes of treatment, and are allied with a general low condition that the associations of home and freedom from anxiety may be expected to cure.

The manufacture of brilliant-green as well as most of the other aniline dyes was confined to Germany, and probably the available stock in Britain is very small, but any one who has seen the results of its use in septic wounds would not hesitate to press on the newly started industry the advisability of preparing this substance for a more extended clinical test of its utility. Fortunately a little goes a long way.

THE PHYSICS OF A SURGICAL DRESSING, WITH SPECIAL REFERENCE TO THE HARMFUL EFFECT OF USING IMPERMEABLE MATERIAL OVER SEPTIC WOUNDS.

BY

LIEUT.-COLONEL A. PRIMROSE, M.B., C.M.EDIN.,
M.R.C.S.ENG.,

CANADIAN GENERAL HOSPITAL.

A NUMBER of most interesting papers by Sir Almroth Wright have recently appeared in the BRITISH MEDICAL JOURNAL, in which he demonstrates by a most complete series of ingenious laboratory experiments a method of securing the drainage of septic wounds received in war. He further gives an account of the practical value of these methods as employed in the treatment of men wounded in France during the present war. In his last communication, Part III of his lecture on "Wound infections and their treatment," he gives his scheme for the practical treatment of wound infections "from the first-aid post back through the whole system of hospitals." In the field ambulance he applies a wet dressing of 5 per cent. solution of sodium chloride and 0.5 per cent. sodium citrate, and he states, "over the top of all ought to come a layer of *impermeable protective tissue*" (the italics are mine). I wish to suggest that as a scheme for "drainage," the effectiveness of the dressing is entirely upset by the "impermeable protective." It should be noted, too, that in the same paragraph he definitely states that his object is "the procuring of drainage."

My attention was first called to the harmful use of impermeable material such as protective, oil-silk, rubber adhesive, etc., by a paper on the physics of a surgical dressing published about ten or fifteen years ago in the *Annales de l'Institut Pasteur*. Since reading it I have had many opportunities of observing clinically, in my hospital wards in Toronto, the deleterious effects of impermeable dressings.

The experiments, so far as I can recall them, were of the following character: An animal was prepared by shaving a portion of the skin surface and then an area was excoriated sufficiently to draw blood. This area was covered with powdered strychnine and a piece of oil-silk was secured over it, so that evaporation from the surface was prevented. The animal died of strychnine poisoning. Another similar experiment was done, save that the oil-silk was replaced by an absorbent dressing, allowing of evaporation from the surface and absorption of secretions into the dressing. These animals showed no symptoms of poisoning. Similar experiments were done with some virulent bacteria, with similar results: under impermeable oil-silk septic absorption occurred, and under a simple absorbent dressing no sepsis resulted. There were, too, a series of laboratory experiments conducted to show the value of absorption into the dressings and the method of securing it by free evaporation from the surface. A flask was filled to half its capacity with water, and a wick of absorbent gauze saturated with water was placed so that one end of the wick lay in the water and the other projected beyond the mouth of the flask so as to form a tuft. A fragment of some aniline dye was placed in the gauze level with the neck of the flask, and very soon the gauze tuft projecting beyond the mouth of the flask was stained with the dye. A similar experiment was carried out with, however, the addition of a bell jar placed over the flask to prevent evaporation; the addition of the bell jar not only prevented the aniline dye from rising into the projecting tuft, but the dye actually descended to some extent towards the water in the flask. I will not vouch for the accuracy of detail, but I attempted to repeat one of these experiments in the laboratory tent in our hospital here. I took two small flasks, each about one-third filled with water; I saturated wicks of gauze in water, and immersing one end of the wick in the water in the flask, the other end was allowed to project as a tuft beyond the mouth of each flask. I inserted a fragment of crystal violet in the gauze at the level of the neck of the flask; I then tied a piece of oil-silk as a cap over the top of one of the flasks, allowing the gauze tuft to project within this protective cap. After some hours the dye had risen into the tuft of gauze projecting from the unprotected flask; on the other hand, in the flask covered by oil-silk

the dye had failed to rise in the tuft, and had descended somewhat in the wick. This last flask was left overnight, and next morning the oil-silk was removed. Within an hour the dye mounted to the top of the tuft.

I have made many clinical observations as to the effect of impermeable dressings. I may cite one example: A woman was desperately ill with subphrenic abscess. I succeeded in establishing drainage, and her condition improved. Some ten days afterwards I was disappointed to find her temperature rising; the frequency of the pulse increased, and there was every evidence of a recrudescence of serious symptoms. I had not seen the dressing for a few days, and I found that the nurse had placed a large piece of oil-silk over my dressing in order to protect the bedclothes from getting soiled. I at once suspected the impermeable covering as responsible for the trouble, and therefore continued to apply the same type of dressing, with, however, the omission of the oil-silk. The patient improved promptly, and all symptoms of absorption disappeared. The sister in charge of the case, on my explaining what had occurred, made a somewhat shrewd observation. The sister told me that she had observed, when a moist piece of alembroth gauze (charged with aniline dye) was applied under oil-silk to the unbroken skin, the dye stained the skin deeply so that it could not be removed by washing; on the other hand, moist alembroth gauze without oil-silk never produced staining. This, indeed, is a good demonstration of the effect of impermeable coverings over the dressing.

The hospital with which I am at present connected has only been in operation some six weeks, and hardly a day passes but patients are admitted with impermeable coverings over septic wounds. In one a septic thumb had been opened two days previously, and when the patient came to me a piece of oil-silk formed a cap over the entire thumb; outside that was some wool and a bandage. Another man had a septic wound of the leg dressed with moist gauze held in place by a patch of adhesive plaster, which overlapped the gauze in all directions. We have already seen dozens of similar cases in our short experience here of the employment of impermeable coverings over moist dressings. We have been able to note, too, the prompt improvement on the omission of that covering in our dressings; frost bites with broken skin, shrapnel and bullet wounds—I am within the mark when I say that by far the majority of all septic wounds admitted have had an impermeable covering. The custom is unquestionably widespread.

What has tempted me most to write this note is the fact that so high an authority as Sir Almroth Wright advocates the use of impermeable protective over his dressing. This covering, I fancy, is added for some specific purpose, but its object is not stated and there has been nothing of similar character used in his laboratory experiments. It is true it increases the penetrating power of an antiseptic, but Sir Almroth Wright's avowed object is drainage, and beyond all doubt it is infinitely better to depend upon drainage into the dressing than attempt to render a wound aseptic by confining the discharges and driving the antiseptic in.

Impermeable coverings used for the purpose of preventing evaporation are, indeed, sometimes useful. Thus, in a healing ulcer one finds the healing process will proceed well under a moist piece of lint entirely covered by protective; so, too, one uses it in skin grafting. Such dressings are removed easily, they do not stick, and the delicate epithelium is not disturbed on taking off the dressing. The impermeable covering is often a favourite dressing, too, for the very reason that "it does not stick," and particularly in children one is tempted to use it because the dressing can be changed without pain. The cases, however, in which its use is justifiable are only those which are either aseptic or have a very small degree of infection—cases, in fact, comparable to those Sir Almroth Wright speaks of as capable of being closed by secondary suture. Even in these cases, however, we sometimes fail to secure success, and when employed we should carefully watch the results.

In my opinion the best dressing for septic wounds is a moist dressing, and we found the hypochlorous acid solution wonderfully effective. The moist dressing is applied directly to the wound, and over this dry gauze. Everything should be done to favour free evaporation from

the surface and absorption into the dressing, which should be frequently changed. I am convinced it would be greatly to the advantage of the wounded if impermeable protective and oil-silk were entirely removed from the surgical armamentarium of the army. Their use in surgery is very restricted, and as they are employed in military surgery at present they do far more harm than good.

FULHAM MILITARY HOSPITAL.

SEPTIC COMPOUND FRACTURES.

At the fourth clinical meeting of the staff of this hospital, on January 11th, Dr. BELFRAGE opened a discussion on septic compound fractures due to gunshot wounds. He outlined the chief indications as follows: (1) Vigorous treatment of the sepsis; (2) the securing of comfort to the patient and ease of nursing; (3) early movement of the joints; (4) correction of deformity. He had found the ordinary splints of little use, and anticipated much help from Mr. Hey Groves's modification of Hodgen. He emphasized the desirability of paying more attention to obtaining a useful limb than to accurate apposition of the fragments. It was doubtful whether extension could be usefully employed in the early stages; later on the fragments could be adjusted under an anaesthetic.

Mr. CHAPPEL thought that in the arm the exact position of the fragments was often not of vital importance in securing a useful limb; but in the leg the necessity of parallelism for walking dictated the greatest care as to their position. He advocated operation where the disturbance of the fragments rendered it necessary, but in septic cases it was essential to wait until the sepsis had been dealt with before attempting plating. He also referred to a great truth established by Sir Arbuthnot Lane—that in dealing with a much comminuted fracture it was not necessary to get the whole circumference of the ends approximated. If a small portion were put in apposition the gap would be filled by new bone laid down if the after-treatment were suitable.

Mr. LEE said that generally there was too much haste to remove sequestra. They should be left till complete separation occurred, for frequently an apparent sequestrum proved to be a focus of new bone formation. He emphasized the importance in the treatment of sepsis of leaving, or if need be making, a very widely open wound; the surgeon should not meantime be too anxious about the displacement of the fragments.

Dr. CARNEGIE DICKSON, pathologist, referred to the extreme rapidity with which cancellous tissue might be absorbed to make room for active marrow in acute general diseases, and with regard to the duration of a septic focus, referred to a case in which a projectile had been removed six months after complete healing, and at the operation pus was found containing organisms of feeble vitality but still capable of growth.

Dr. KINNIE WILSON expressed the opinion that in some cases the late disability of muscular movement was greater than could be explained by mere disuse. Some cases were explicable on the theory that a defect was present in the reflex arc through the spinal cord. Possibly the constant afferent impulses from the diseased focus produced a dynamic functional change in the anterior horn cells and consequent muscular atrophy. Electrical treatment in such cases was more important than massage. Repeated efforts on the part of the patient sometimes sufficed to reawake innervation through the reflex arc.

The chairman, Major PARSONS, O.C., advocated putting up fractures under x-ray illumination. The prevention of movement in the injured tissues was of great value in limiting sepsis. The joint involved in a septic process required immobilization, while the other joints required to be moved. Continuous extension was valuable; often the weight applied was too small; attempts should be made from the first to rectify deformities. In treating sepsis

transverse incisions, which tended to remain gaping, were very important. The introduction of solid sodium chloride, which had given good results in France, should be tried, as also the introduction of solid urea, on which Professor Symmers of Belfast had reported favourably. He had obtained good results in septic conditions by Bier's treatment before the war and thought greater use might be made of it.

Reports of Societies.

THE DAILY FOOD RATION OF GREAT BRITAIN.

At the meeting of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland on January 14th, Professor W. H. THOMPSON made a communication on the daily food ration of Great Britain. He said that from a survey of the total food supply of Great Britain for the year of the first census of production (1908), the only year for which it was so far possible to make anything like an accurate computation, the daily food supply per man of the population, as calculated from the returns, came out to be as follows:

Flour and meal ...	14½ oz.	Cheese ...	¼ oz.
Flesh meat ...	8 oz.	Condensed milk ...	3 oz.
Fish ...	2 oz.	Less than half an egg.	
Potatoes ...	15½ oz.	Fresh fruit ...	3½ oz.
Other vegetables ...	4½ oz.	Dried fruits and nuts ...	½ oz.
Milk ...	4 pint.	Cocoa and choco ato ...	1½ oz.
Butter ...	1 oz.	Salad oil ...	160 oz.

This ration provided the following:

Protein ...	101.49 gm.	Fat ...	136.36 gm.
Carbohydrate ...	587.12 gm.	Energy value ...	4,127 calories.

The returns did not, however, include all the home supply of cheese, eggs, poultry, or rabbit meat. The estimate of green vegetables consumed as human food, particularly of cabbage, was probably also too low. Making additions to cover these omissions, would bring the ration up to:

Protein ...	104.26 gm.	Fat ...	138.83 gm.
Carbohydrate ...	587.84 gm.	Energy value ...	4,167 calories.

As a fair estimate it would be safe to say that the British food ration per man per day does not exceed:

Protein ...	105 gm.	Fat ...	140 gm.
Carbohydrate ...	590 gm.	Energy value ...	4,190 calories.

Making deductions for loss in distribution, the value of the ration, as purchased, would approximately be:

Protein ...	97 gm.	Fat ...	129.5 gm.
Carbohydrate ...	546 gm.	Energy value ...	3,875 calories.

This did not provide more than enough for moderately hard muscular work. Dr. Langworthy placed the energy value of the ration, as purchased, for moderate work at 3,800 calories. The ration was remarkable in the relatively large amount of fat it contained, but in this respect it corresponded closely with the estimate of the German food supply before the war, as published by the Eltzbacher Committee. Professor Thompson drew two conclusions: (1) That the tendency in urban and industrial populations is to increase the consumption of fat at the expense of the protein; and (2) that the ration could not well be reduced without endangering the efficiency of the working man. Economy could, however, be introduced by substituting protein from vegetable sources for a further part of the more costly meat supply.

THE *Journal of the American Medical Association* states that 2,451 members of the medical profession in the United States and Canada died during 1915. The average annual mortality for the period from 1902 to 1915 inclusive was 15.71 per 1,000. The chief causes of death in order of frequency were senility, heart disease, cerebral haemorrhage, pneumonia, accident, and nephritis. The age at death varied from 21 to 102, with an average of a little over 59 years. The number of years of practice varied from 1 to 79, the average being 32 years 4 months and 26 days. There were 104 deaths from accident and 44 cases of suicide. Of those who died, 1 had been a member of Congress; 2 governors of States; 4 United States consuls; 11 members of State senates; 39 members of the lower houses of legislatures; 35 had been mayors; 33 aldermen, and 62 had served as justices of the peace, as clerks in the Government service, or in various other civil positions.

Rebielus.

NERVE STRUCTURE AND THE MIND.

PROFESSOR LLOYD MORGAN has defined instinctive behaviour as "that which is on its first occurrence independent of prior experience; which tends to the well-being of the individual and the preservation of the race; which is similarly performed by all the members of the same more or less restricted groups of animals; and which may be subject to subsequent modification under the guidance of experience." He regards it as a more or less complex response to a more or less complex internal or external stimulation, dependent upon inherited nerve structure. This is as much as to say that instinctive action is action based primarily upon organized racial experience, whereas, of course, intelligent action, properly so called, is based upon individual knowledge and experience. Taking this definition as his point of departure, Mr. N. C. MACNAMARA, in his manual on *Instinct and Intelligence*,¹ traces the parallel developments of the physical structure and the psycho-physiological functions of the nervous system from its rudimentary dawn in the nucleus of the protozoa and the palpoils of certain hydro-medusae, through the circumoral and radial nerves of the starfish, the gangliated chains of the earthworms, the primitive brain of the crustacea and of insects, and through the various grades of vertebrate animals up to its consummation in man. He shows how side by side with increasing complexity of structure there appears a corresponding power of self-adaptation on the part of each new organism to a wider range and more intricate quality of demands in response to stimuli from within and from without. He shows, too, how the power of modifying instinctive response by the results of individual experience and of ultimately controlling the former by the latter to a considerable extent is conditioned by the development of those pallial or cortical elements which culminate in the sensori-motor and association areas of the human brain. Broadly speaking, it may be taken as proved that the ratio of development of the cerebral cortex to that of the basal ganglia is that of the transcendence of instinctive by intelligent behaviour. The functional ideal is not, however, a tyrannous domination, still less a suppression of the one set of activities by the other, but a harmonious co-operation between them, in so far as that is compatible with the due supremacy of the higher and later evolved.

In Mr. Macnamara's opinion the prevailing methods of education tend to ignore the just claims of instinctive capacities, which, as he justly remarks, can be modified but not eradicated. In his last chapter he has given some suggestions as to the means of remedying this defect, which are worthy of careful attention by those concerned. But, apart from this practical purpose, the book is well worth reading as a singularly clear and concise account of an important and interesting subject.

PATHOLOGY.

In the preparation of the sixth edition of his *Textbook of Pathology*² Dr. ALFRED STENGEL has associated himself with Dr. HERBERT FOX, Director of the Pepper Laboratory of Clinical Medicine, University of Pennsylvania. Dr. Stengel states in his preface that several sections of the book have been very largely recast or almost wholly rewritten. New sections on transmissible diseases and on the pathology of diseases of the eye, ear, and skin, "brief and general in scope," have been added, and the chapter on "technic" has been omitted. It seems doubtful whether the new sections have done much, if anything, to enhance the value of the work as a textbook for students. Twenty pages, several with illustrations, are made to suffice for the pathology of diseases of the eye, with the result that this chapter is little more than a glorified dictionary of medical terms. Unfortunately in this chapter, as well as in other parts of the book, sufficient care has not been taken to bring

statements made elsewhere in the work into line. Thus on page 964 we read that "the body of the cornea is composed of lamellated epithelium," a statement which cannot be accepted, whereas on p. 119 we are told that the cornea is composed of "layers of parallel fibres." On p. 953, under the heading "The Lids," is the following paragraph: "Edema may be traumatic or accompany ocular inflammation. It occurs in angio-neurotic edema and exophthalmic goiter." Brevity of this kind is misleading. The claim that the book has been subjected to extensive revision to bring it up to date is undoubtedly justified, but the process might have been carried further. For instance, in discussing fat embolism, the statement that sudden death may occur when a large number of pulmonary vessels are obstructed by oil-drops still stands unqualified. Experience has shown that death, certainly due to this cause, may not ensue for many hours or even days, and that a train of symptoms is set up which are sufficiently characteristic to be of real diagnostic value. In the section on "Edema" on p. 73 the authors state that increased blood pressure alone is a sufficient cause, and make no mention of Starling's well-known work controverting this view. Yet on the next page they say that increased permeability of the capillary walls "probably plays a part in every case of edema." The sections in the chapter on retrogressive processes suffer from want of a clearer arrangement of the subject matter. The section on fatty degeneration is a case in point. Under pneumonokoniosis we are told that inhaled substances probably do not reach the alveoli, but are caught up by the "bronchial cellular cilia"; and yet, in dealing with pulmonary tuberculosis, it is said that "the tubercle bacillus is carried directly to the lungs in the inspired air, or more rarely it may lodge in the pharynx," etc.

No attempt is made to classify tumours. The term "lymphadenoma" is used for any tumour of a lymph gland, such as lymphosarcoma, and the terms "destructive adenoma" and "malignant adenoma" are retained; the student may find them misleading. Splenic anaemia is dismissed in nine lines; Gaucher's disease is mentioned in the text, but not in the index. In the latter anaemia of the spleen and splenic anaemia are twice grouped together under the same heading, as though synonymous terms. The section on congenital diseases of the heart is inadequate, and although full discussion of such a subject is not possible in a general textbook of pathology, it was to be expected that some reference to Keith's work on the bulbus cordis and its bearing on pulmonary atresia would have appeared. In the etiology of haemoptysis (p. 541) no mention is made of infarction, whilst elsewhere occlusion of a bronchiole is given as a possible cause of the latter lesion. The statement on p. 627 that "herniae occasionally are congenital, more often they are acquired," seems to be an inversion of the fact. Under "Diseases of the bones," on p. 837, is a paragraph headed "Congenital rickets, or chondrodystrophia foetalis or achondroplasia, etc." The essential difference between rickets and chondrodystrophia, and also osteogenesis imperfecta, has now been made sufficiently clear, from the point of view of morbid histology, for the term "congenital rickets" to be deleted in this connexion. Its retention obscures the pathology of these diseases. The essential underlying change in rickets—namely, the excessive production of uncalcified osteoid tissue in the bones affected—is not brought out.

ZOOLOGY.

THE fact that SHIPLEY'S and MACBRIDE'S elementary textbook of *Zoology*³ has now passed into a third edition is sufficient testimony to its merits and popularity. Written primarily for students of zoology, it is in only a slightly less degree valuable and helpful to the student of medicine. The growth of our knowledge of such subjects as embryology, cytology, parasitology, and tropical medicine has shown how important to medical men is a knowledge of zoology. The book is comprehensive, dealing in turn with all the orders of invertebrata and vertebrata. The method adopted is to deal in some detail with a typical representative of the order, and then to add a short account of those

which have undergone special variation. The detail in which these types are considered naturally varies, and a special effort has been made in the cases of the cockroach, the garden spider, and the crayfish to give the student a conception of insects, arachnida, and crustacea as "going machines." All through the book, moreover, as the authors claim in their preface, they have endeavoured—and we think successfully—to associate the description of structure with an account of its purpose and function. If we have any complaint to make it is that so meagre an account is given of the theromorphs, a group of animals of special interest because they have thrown a flood of light on the evolution of the mammalia. The authors would have been well advised to have spared some few pages and illustrations for this particular group. The book is written in an easy, interesting style, and forms an admirable introduction to such larger works as *The Cambridge Natural History* or *The Treatise of Zoology*, edited by Sir Ray Lankester.

NOTES ON BOOKS.

PROFESSOR E. B. POULTON, in his Romanes Lecture¹ delivered at Oxford in December, anticipated a good deal of what is contained in the memorandum put out by a committee of men of science to which we referred at some length last week (p. 209). He gives chapter and verse for the glycerine story, tracing it to a statement made in the Prize Court by the Solicitor-General, Sir F. E. Smith, on July 20th, when, according to the report in the *Times*, he said "it had been discovered recently that glycerine could be made from lard." The oddest thing about the incident is, perhaps, that the Solicitor-General was appearing for the Treasury, which, one might have supposed, must have had the assistance of the Board of Trade in framing his instructions. In a debate in the House of Commons a few days afterwards (July 26th), the Parliamentary Secretary to the Foreign Office grew very angry with Major Hunt because he had said that the Government was saying to men, "Come and defend your country; you are badly wanted; your country is in the greatest danger," and at the same time said to the most inhuman nation that probably any nation has ever had to face in modern times, "We will allow you, although we could prevent it, to be provided with the ammunition to kill our soldiers, whom we are begging to defend us and our country." Lord Robert Cecil exclaimed that Major Hunt seemed really to believe what some of the more ignorant and more venomous public prints were not ashamed to say. The discussion was about cotton, but it might equally have been about glycerine and the lard or other fats from which it can be made. The main object of the lecture was to show what the country had lost by the national neglect of science, and in repelling the suggestion that improvement in this respect would foster the callous materialism and brutality which have been such a shock to the world, Professor Poulton said: "It is not German science which is responsible for the horror, but the German spirit, which has used science, as it has used everything else except a sane psychology, for its own ends."

The *Medical Clinics of Chicago*² is a bi-monthly periodical started by its publishers to satisfy a demand of the medical practitioners in and about that great city. Its matter is furnished by clinical teachers in Chicago, and covers the field of internal medicine. It consists of transcripts of expositions and discussions of cases held at the bedside or in the lecture theatres of the Chicago hospitals. Among the cases dealt with in the first number of the periodical are instances of lung abscess, nephritis, gout, infantile tuberculosis, leukaemia, heart failure, aortitis, aneurysm, and the like. There is a natural directness about these transcripts that makes them easy reading. This feature, perhaps, militates against the attainment of the completeness and exactitude of statement met with in carefully composed papers as contrasted with speeches and orations. The reader will find cases of greater and of lesser interest described in these pages. He will not learn much that is new as to their symptoms, signs, or etiology, and no great calls will be made upon his intelligence. The periodical should be of interest to medical men who wish to furnish up a somewhat casual and out-of-date acquaintance with practical medicine.

MATERNITY AND CHILD WELFARE.

DURING the last few years the focussing of attention on the loss to the community caused by excessive infant mortality has resulted in many voluntary efforts for dealing with some of the causes of the evil. Numerous mission stations of a modern order have been opened in the poorer quarters of our cities under such names as "The Baby's Welcome," "Babies' Clinics," "Infant Consultations," "Mothers' Kitchens," "Schools for Mothers," and the like. When in the hands of ordinarily capable workers these centres have had a degree of success that has speedily called for the extension of their work, and with that the demand for more money and State support. The State, in the guise of certain Government departments, has lent a considerable measure of support, and from the early tentative efforts at baby culture there has now sprung a full-fledged State scheme which is urged for adoption by the country as a whole.

In several circulars issued by the Local Government Board during the years 1914 and 1915 the scope and intention of this organized scheme of baby culture is set forth. The following is a summary of that scheme.

It is intended that the work of each local authority should be directed along two main lines of endeavour—first, the visiting of all mothers *in fact*, and, in so far as may be possible, of all mothers *in expectation*; secondly, the establishment in every area of centres where the examination of mothers, babies, and children under school age should be undertaken at regular intervals. The purpose of these visits and examinations is stated to be in the main to give advice, in general on domestic hygiene, and in particular on the difficulties of the individual mothers and children. But the possibility of some sort of simple medical treatment is held out as one of the advantages of the centres.

The scheme crystallizes round the Notification of Births (Extension) Act, 1915. With the extension of compulsory notification of birth to the whole country, each medical officer of health has immediate information of the birth of a child. From that notification radiates the health visitation as part of the normal public health work of the district. Within two or three days of the notification an official visitor is sent by the medical officer of health to such homes as he judges advisable. The visitor sees the mother and baby, gives advice on the care of the infant, takes a general survey of the home, the cleanliness and sanitation thereof, and in particular urges the mother to take her baby as soon as possible to the "centre," and to consider that centre as in some sort the place for the standardization of her infant; there she will know how it fares, if its height, its weight, and its health are as good as may be, and there she will receive advice on all the difficulties that occur in the upbringing of the little one, and all this right on until the child is entered on the books of the local elementary school, when the record will be handed on to the school doctor. When the little one comes to learn of all this it will be able to echo in truth the words of the psalmist: "In thy book all my members were written." But the work of the centres will not be limited to the oversight of the mothers *in fact* and their infants. It is intended that the work should have a very definite extension to the mothers *in expectation*. There is no legal notification of pregnancy, so that the medical officer of health has to trust to the willing co-operation of the medical men and midwives of the district for information concerning the mothers in expectation, or to such chance knowledge as may come to him through voluntary agencies or his own health visitors. The object of obtaining this information is that the expectant mothers should be urged to attend the centres for medical examination and that the health visitors should visit them at their homes.

The Health Visitors and Their Work.

Up to the present the nature of the qualifications of the visitors has not been fixed on definite lines. It is suggested by the Department that the three most useful qualifications for non-medical health visitors are those of: (1) A trained nurse, (2) a certified midwife, and (3) a certified sanitary inspector. The first training will enable the visitor to give important instruction in the hygiene of child life; the second will enable her to supplement the work of the

midwife even to acting as an inspector of midwives; and the knowledge of sanitary work will enable the visitor to appreciate the state of a house and its sanitary arrangements, and bring her into intimate relation to the regular sanitary officers of the district.

The nature of the advice to be given to the mother *in fact* is not outlined: it may be presumed to depend on the individual case of mother and child. But on the visitation of the expectant mother there is an indication in some notes prepared by Dr. Janet Lane-Claypon. The feeding and clothing of the woman are subjects for suggestion, the improvement of her health, and in particular the state of her teeth, the care of the breasts, the best methods of combating constipation and the recommendation of aperients are to be dealt with. The state of the house is to be looked into. The provision of clothing for the expected infant is to be a matter of kindly inquiry and suggestion. Much stress is laid on the necessity for impressing on the woman the advantages of breast feeding, the best means for securing a good supply of milk, and the best times for feeding. The scope and character of the advice suggested is excellent, and if that given to the mother *in fact* is as good as that proposed for the mother *in expectation*, many women and many infants will be the better for the advice.

With regard to the number and frequency of the visits, the official suggestion is that the health visitor should go first within two or three days of the notification of birth, and that eight visits should be made during the first year of the child's life. Thereafter only sufficient are to be made to keep in touch with the child, so as to encourage attendance at the Child Welfare Centre for purposes of medical inspection at such intervals as will enable a record to be kept of health and sickness up to the time when school attendance begins.

The Centres.

It will be evident from the foregoing that the main work of the centres will be with the mothers and the children. But the circulars show that a very strenuous effort is to be made to increase to the greatest possible extent their work in relation to the expectant mothers.

The actual scope of work of the centres is best given in the official terms: "The chief object of the centre is to secure the medical supervision of the expectant and nursing mother and of her child. This supervision takes the form of a medical consultation, followed by the giving of hygienic advice, and by treatment, especially for minor complaints, when local circumstances indicate the need for this."

It would appear that the expectant mother, when persuaded to attend the clinic centre, will only be seen once in the ordinary course of events. She would be examined, the urine may be tested, and advice on the care of her general health, with particular instructions on any obvious difficulties, given. A supply of abdominal belts and bandages for varicose veins would be available for sale at cost price. Patients found to have serious symptoms would be referred to a private practitioner; "no responsibility should be undertaken at the centre for the continuous treatment of serious illness."

Three sets of records are to be kept, thus:

A. Mother.

Name.....	Age.....	Address.....
Patient of		
Date of first attendance.....		
Date of expected birth		
Occupation (Present		
Occupation (Before marriage		
Occupation of husband		
Former pregnancies	1st	4th.....
(including miscarriages)	2nd	5th.....
	3rd	6th.....
(State in each case whether the child is still living, and if not, cause of death.)		
Previous medical history of patient.....		
Present health (teeth, constipation, digestion, obstetrical, etc.)		
Adequacy of food		
Arrangements for confinement:		
Present condition (doctor's note)		
Treatment recommended		
General notes		
Dates and notes of subsequent attendances (on back page).		

When the baby's turn comes to attend the centre it is natural that it should be the chief focus of attention. "Commonly, it will be desirable to secure that each infant attending the centre is seen by the doctor at least every

four or six weeks. These consultations should be arranged more frequently, if the health visitor in the intervals finds that the infant is not progressing favourably. After the early months of life less frequent attendance will be needed, but the consultations should suffice to secure early recognition of rickets, etc. After the child has reached the age of 2 or 3 years, efforts should be made to secure a medical examination at quarterly or half-yearly intervals, until the child is entered on a school register." Record of the state of the infant is to be kept, thus:

B. Infant.

Name.....	Date of first attendance.....
Address	
Date of birth.....	Maturity.....
Weight at birth	
Health prior to attendance	
Method of feeding.....	
Digestion and bowels	
Sleeping	
Clothing	
Bathing	
Open air	
Present state and weight	
Doctor's notes (including nutrition)	
Dates and notes of subsequent attendances (on back page).	

Besides these records of the mother and child there is to be a record kept of the visits to the home, thus:

C. Home Conditions.

Occupants of house.....	Adults.....	Under 15.....
Number of rooms and size		
Sanitary conditions		
Ventilation		
Light		
Repair		
Dampness, etc.		
Cleanliness		
Refuse receptacles.....		
Social conditions and habits		
Dates and notes of revisits (on back page).		

So much for the general scope of the work. There remains to discover the medical arrangements.

At the end of Dr. Newsholme's report we find the following:

The value of a centre depends chiefly on the medical advice given in it. The late Professor Budin, the distinguished founder of infant consultations, said: "An infant consultation is worth precisely as much as the presiding physician." This is even more true for the antenatal work of the centre.

The medical arrangements for the centres are left entirely in the hands of the local authority:

Each local authority opening a centre will decide the best arrangement for medical service. An officer of the local authority may undertake this. The arrangement made should, so far as practicable, be one which will receive the general approval of local medical practitioners. This may sometimes be secured by appointing a practitioner not practising in the district. It is less satisfactory to have a rota of doctors. The last-named arrangement should not be entertained unless it is provided that the same doctor will attend at consecutive consultations for not less than six months.

With regard to the cost, the memorandum assumes that the health visitors will be officers of the sanitary authority, so that their salaries need not be reckoned as part of the working expenses of the centre, which would comprise "the doctor's salary, rent, rates, taxes, lighting, heating, caretaking, and a few minor items, including drugs and medical appliances." The Local Government Board will pay 50 per cent. of the amount spent on approved expenditure for the above purposes, but it is thought that in many instances the centre can be conducted on premises used for other purposes, so that no rent need be paid.

(To be continued.)

SOME years ago the New York Department of Health established a number of clinics for school children suffering from diseased tonsils and adenoids. Nearly one-third of all the operations on school children for these conditions in the city during the past three years have been performed in them. It is now considered that the dispensaries and hospitals should take this work in hand. The Associated Out-patient Clinics have, we learn from the *New York Medical Journal*, recently called attention to the need of suitable provision for dealing with children suffering from these affections, and the State Charities Aid Association and the Public Health Committee of the New York Academy of Medicine have expressed the opinion that all adenoid and tonsil operations on children should be done under general anaesthesia, and that hospitals where such operations are performed should be equipped to keep their patients in the wards for at least eighteen to twenty-four hours after operation.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

EXPERIENCE OF THE NEW LIGHTING REGULATIONS.

THE restrictions introduced in January by the Home Office Order concerning lights on motor cars form the subject of complaints by many doctors, on the ground that these new regulations make it impossible for them to drive on dark country roads, with their lighting equipment masked in accordance with the new regulations. It will be recalled that the Medical Secretary of the British Medical Association wrote, on December 31st, 1915, to the Home Office stating that a number of letters had been received by the Association from practitioners in rural areas pointing out the inconveniences and dangers which might arise from the new Order that has come into force this year, and asking for some relaxation of it to be made as regards the cars of doctors when in use for professional purposes. The official reply claimed that in the framing of the new regulations the needs of medical practitioners who had to travel by road at night had been specially had in mind, that the new Order permits the use on country roads of sidelights giving a brighter light than has been allowed in many areas under the existing orders, and will be found to allow sufficient light for driving at ordinary speeds, even on narrow and winding roads; and concluded with an expression of the Secretary of State's regret that he could not authorize any general exceptions from the provisions of the Order. This correspondence was published in the SUPPLEMENT to the JOURNAL on January 15th. Subsequently a question was asked by Mr. Perkins in the House of Commons on January 19th. In commenting on it editorially in the JOURNAL it was remarked that it was understood that experiments had shown that, by suitable alteration of sidelamps, the full amount of light allowed by the Order could be obtained.

FALSE PREMISES AND REAL DIFFICULTIES.

Now there come complaints from many doctors concerning the new regulations. These objections differ from former medical comment on the subject in this important particular, that they are the result of actual individual experiences of the working of the new regulations. Inasmuch as the sum of the whole is the allegation that the new restrictions are frankly impracticable in many cases, and as there appears to be some doubt as to the manner in which the degree of restriction imposed was arrived at, I ought to make it clear that the authorities did not confine their preliminary experiments to the experience of a single make of very powerful and considerably expensive electric lighting equipment, as appears to be rather widely assumed. Not only was advice, criticism, and suggestion sought from the Royal Automobile Club and the Automobile Association, which is the largest organization of motorists in the world, but the leading lamp makers, including those not concerned with the electric variety, were besides called on to assist. Each placed its technical experts at the disposal of the authorities.

It is necessary to point this out because, if the Order were the result of an experiment with only one variety of an expensive electric lamp, it would be practically equivalent to compelling medical men, in common with other motorists, to scrap their car lighting equipments, and, at heavy expense, to fit something at least as costly as the electric plant wrongly assumed to be the only type tested.

The real difficulty appears to be that medical men in general, like other motorists, have relied hitherto mainly on their headlights for night driving. It is only of recent years that the power of sidelights has been sufficiently increased to render them really serviceable, especially when equipped with discs in accordance with the new regulations affecting wide areas. The oil lamp is admittedly lacking in sufficient power. It is therefore in any case a choice between the acetylene variety and the electrical. Acetylene is the cheaper sort if the car is not already fitted with accumulators, if not a dynamo.

COST AND AVAILABILITY OF ACETYLENE LAMPS.

But the acetylene variety is perhaps not so absolutely steady as the electrical sort on more or less indifferent road surfaces, such as the medical practitioner has to reckon

on traversing in these days. The cost to the medical man who has hitherto had only oil lamps is, for example, £5 17s. 6d. for the English-made Lucas "King of the Road" acetylene side lamp, specially designed to comply with the new lighting order, this price including generator and tubing, but not new brackets should the dimensions of the existing ones be unsuitable. Without the generator the cost is £4, the aim of the design being to meet the requirements of motorists whose cars are not electrically lighted. These lamps are fitted with Mangin lens mirror-reflectors and provide a light sufficient for careful night driving. They fit standard flat brackets, can be supplied with frosted glass if so desired, and have a glass diameter of 5 in. That there is a considerable demand for this acetylene lighting is evident by the fact that immediate delivery cannot be given, though sets can be supplied at about a week's notice.

Admittedly the cost involved is a serious item to the country doctor; but it is scarcely comparable in importance to him with the rise of 4d. a gallon for petrol that has occurred this week. Discarded acetylene side lamps of unsuitable patterns are, of course, of no realizable value; but discarded oil lamps are in more demand now than they have been for many years. This is evident by the rush there has been on some of the secondhand dealers for oil lamps for service on the most luxurious types of town cars off which the electric lights have been taken temporarily because of the lighting regulations that are in force in the metropolis itself. For my part, I could not recommend the medical practitioner having oil lamps adapted to acetylene; at least, I have not yet come across anyone who has had absolutely satisfactory experience from this method of procedure. The best thing to do is to sell unsuitable oil lamps to dealers in the metropolis, where there is some use for them.

THE POSITION TO DATE.

As far as the position goes to date it does not appear to be gainsaid that, if suitable electric or acetylene sidelamps are installed, the new regulations are practicable, though not desirable, from the individual driver's point of view. In point of fact, no restriction of lighting could be desirable when considered from the sole aspect of driving as driving. The practical point, from which there can be no getting away, is that during this war, in face of the advent of aerial navigation and of the enemy's enterprise in that connexion, we must all make shift with lighting that is frankly inadequate. The contention that all this insistence on darkness at night is mere "fussiness" and quite unnecessary fails in face of the fact that Paris, hitherto illuminated at night, is henceforth to be kept dark, like London. This has been found necessary in the light of experience of the last Zeppelin raid on the French capital. Likewise, during the last raid on the midlands, through distribution of authorities, one important manufacturing centre was illuminated as usual in a manner that could be seen by aerial navigators for more than thirty miles away, and which gave them exact bearings for attacks on neighbouring centres. Hence the measures subsequently taken to ensure uniformity of town darkness. Therefore the vital question is, How inadequate can we have car lighting? From the military aspect, there ought to be no lighting of vehicles at all; from the civilian one, there ought to be no restriction on the average amount of lighting employed in peace time; from the point of view of the medical man, in common with other motorists who have need to drive at nights in the areas where the new regulations obtain and whose present sidelights are not sufficiently powerful when employed according to regulations, those regulations are equivalent to a cash levy on him of anything from £4 upwards. It is harsh, but there are worse things in war time. Further, unquestionably the new regulations have not been in force sufficiently long to establish evidence of a sufficiently strong and general character to call for any remodelling of them yet. We may have to do so at a later date, but this thing must be given a fair trial. The authorities cannot be blamed justly as imposing a hardship on individual motorists because they refuse to allow them to use old and less powerful lamps in other ways than are laid down for lamps in general in the areas in question.

MAKING EXCEPTIONS SPELLS CONFUSION.

To attempt to make exceptions would only lead to hopeless confusion. Proof of this is furnished by the fact that

there appears to be some variation on the part of local authorities as to points of detail in the interpretation of the new regulations. The first thing to do, therefore, is to collect evidence concerning given points that a case may be made for the Home Office to issue instructions that shall ensure uniformity of interpretation.

In regard to discs, on application most of the lamp makers supply their customers with these gratis, while the Automobile Association and the Motor Union supply specially prepared lamp-dimming discs alike to members and to non-members on application—a fact that may be of some service to medical men whether members or not. These discs are equally suitable for use with electric or gas lamps. I know of no means of increasing the power of inadequate oil or acetylene lamps not up to the standard of power allowed by the Home Office regulations; nor do I know of anything material yet being done by the industry towards evolving means of so improving inadequate sets in current use.

It has been alleged, apart altogether from the matter of cost, that new acetylene lights, specially designed in the light of the regulations, cannot be obtained in any case; but I have given above an example of a type that could be got at a week's notice at the time I inquired concerning the point, which was Tuesday of this week. Thus the unavoidable delay cannot be described as of unreasonable or impracticable duration.

THE RISE IN THE PRICE OF PETROL.

The sudden and practically all-round rise of 4d. a gallon in the price of petrol is a very serious thing for the medical profession, because it is an increase of a character on which the doctor can get no rebate on professional grounds such as he receives in respect of the Government duty on motor spirit. Moreover, even in cases where supplies are contracted over a period of a year or more the contracts that have been made recently all stipulate that the price of the fuel shall vary according to the price obtaining at the time at which each delivery of it is given.

It will be recalled that last autumn, when Mr. McKenna introduced his supplementary Budget embracing increased petrol dues, the wholesale firms thereupon advanced the retail price of fuel twopence a gallon more than the total amount of the increased duties, an act which called forth much criticism. A fortnight ago the proprietors of Shell spirit—who have imported somewhat less fuel this year than before because of the temporary cutting off of their supplies from Roumania, and passing difficulties with such of their supplies as derived from Mexico—issued a warning as to the need of every one to economize the use of petrol to the utmost, and hinted that there might be a shortage. The chief rival concern—the proprietors of Pratt's spirit—thereupon announced that there was no shortage as far as they were concerned. Yet a week ago the first intimation of the rise of fourpence in the retail price of fuel came from the group which announced there was no shortage, and the week-end passed without any announcement as to a corresponding advance in price on the part of the firm which had first issued a warning as to possible shortage, and had thereupon been accused of being panicky! Of course, the price of all petrol is going up in accordance with this fresh advance. It is an open secret that the tank steamers in which it is brought to these shores are needed more than ever to convey supplies of fuel for use in the various theatres of war, which are increasing in number so appreciably. Further, the big reduction in the amount of so-called pleasure motoring in these islands and the very appreciable percentage of cars that have been laid aside altogether this year means that the retail trade in petrol will tend to shrink all the time.

AN ANTICIPATORY MEASURE.

It has been alleged that it does not pay the wholesale distributors to sell petrol through the retail trade in this country nowadays. It should be pointed out, incidentally, that after the rise in the price of fuel last autumn the retail distributors, who were then receiving no more profit per gallon than in the days when petrol cost half as much, made an organized protest and received a concession, which also acknowledged a principle to the effect that the higher the price of petrol the more was to be their profit per gallon. Thus every time the Government increases the duty on petrol we are to look for the wholesaler to put on an increase of his own under some excuse

or other, and for the retailer also to have his proportion of the increase—three increases for and in one. Where is it to end? Obviously the future use of petrol appears as a competition in which all but the very rich will fail to continue. The few will be paying prices which will presumably yield as much profit to the trade as was derivable for the much greater quantities of petrol sold when professional men and the public were collectively consuming much more than they are to-day.

Another Budget is due in a month or six weeks, and it will certainly concern the question of imports. In its own interests the Government should see to it that the price of fuel is no longer raised to the consumer, especially of the professional class, other than by Government duty. Thanks to the British fleet, during the war the seas have been open. We have received better motor fuel supplies even than the good ones we had before the campaign commenced. The number of tank steamers in the world has been increased, and the maximum extra duty the Government has imposed in respect of petrol is 3d. a gallon, yet the price of that commodity to the general public has risen 9d. a gallon, which is an additional 6d., and it does not find its way into the Exchequer! The Government should take steps to protect itself and the public, for the importation of petrol yields a substantial revenue. Possibly the present increase in price may be due in measure to an anticipation that the Government may fix a limit of the extent to which the price can be advanced. The present figure, of course, constitutes a record in the story of the motor movement. The amount of the advance made this week in the price to the consumer can scarcely cost a medical man less than £5 a year. It will cost the majority at least twice as much.

As we go to press the Asiatic Petroleum Company, Ltd., has issued a circular to its clients, in the course of which it is pointed out that of the motor spirit requirements of His Majesty's forces the company is supplying five times as much as the whole of its competitors put together. In spite of the great and constantly increasing claims upon the firm's resources, it has determined to maintain unchanged the prices at which it has been selling Shell motor spirit to the public. It will be its constant endeavour to secure that garages shall receive at least one-third of the quantity of spirit which they have been accustomed to receive from the firm and at the old prices, which enables the retailer to sell to consumers Shell I at 2s. 2d. a gallon, Shell II at 2s. 1d. a gallon, and Crown spirit at 2s. a gallon. Obviously, however, these curtailed supplies cannot suffice for all the requirements of medical men and the public, and therefore the majority of motorists will undoubtedly have to pay the higher prices which have already been instituted in the case of other brands of motor spirit.

APPLICATION BY THE ASSOCIATION TO THE BOARD OF TRADE.

In view of the seriousness to many members of the medical profession, especially those in country districts who have to make long journeys, of the rapid increase in the price of petrol, the following letter has been addressed to the Board of Trade:

February 3rd.

Sir,—On January 22nd last I wrote asking whether the medical profession could have some assurance that no obstruction would be put in the way of their buying petrol. To that letter I have up to the present merely received an acknowledgement. A new development has occurred. I am informed this morning that petrol has gone up 4d. per gallon. This is an extremely serious thing for members of the medical profession, most of whom are engaged on work which may accurately be described as national work, for probably more than half of them are now helping to carry on the practices of men who have accepted military service, while in addition many of them are engaged on part time military service. To these men, and particularly men in country practices, an additional 4d. per gallon is a very serious tax, and I am instructed to ask whether some arrangement could not be made whereby medical men could be allowed to obtain petrol on cheaper terms.

The Association is emboldened to make this request because it believes that the recent rapid increase in the price of petrol is due, not to ordinary commercial reasons but to the fact that the Government is anxious to restrict the use of petrol for purposes other than necessary work. If this is so, the Association feels that the medical profession has a claim which is only less justifiable than that of the military authorities. The Association would be very grateful if you could give it at an early date some assurance that members of the medical profession will be given special facilities to obtain petrol for the purposes of carrying on their practices at a special price, and thus relieve the minds of the profession on a point which is causing them considerable anxiety.

I am, yours faithfully,

ALFRED COX,

Medical Secretary

The Secretary, Board of Trade.

British Medical Journal.

SATURDAY, FEBRUARY 12TH, 1916.

TRENCH FEVER.

INCAPABLE of learning by experience, the opponents of antityphoid inoculation are still carrying on their agitation against that invaluable method of protecting our troops abroad. One of their less creditable methods of attack has been to insinuate that perhaps the military medical authorities hide cases of enteric fever by falsely returning them under other names. This, at any rate, was the interpretation placed by the Under Secretary of State for War upon a question asked in Parliament on January 20th by Mr. Will Thorne, who wished to know whether "cases bearing the name of paratyphoid fever, trench fever, pyrexia, and other pseudonyms of enteric fever were included in the totals" given for enteric fever.

It is, perhaps, too much to expect that members of Parliament should follow closely the rapid progress of scientific medicine, but they ought surely to be on their guard against falling into such a trap as this and being made a means of not only diffusing information manifestly incorrect but of spreading an odious insinuation. The great value of antityphoid inoculation has been shown again and again—most recently in a reply by Mr. Tennant to Mr. Thorne in the House of Commons on January 10th—and the fact is so firmly established in this and in other countries as to require no further emphasizing here. Moreover, any one who has taken an intelligent interest in the statistics of sickness in the British army in Flanders, not to mention India, ought surely to have been aware that the disease called paratyphoid fever is distinct from typhoid fever, and that an attack of one does not protect from the other, so that inoculation for the one could not be expected to prevent the other.

With regard to trench fever, however, the belief that it is a form of typhoid has been until quite lately more difficult to combat, because it is only now that the identity of trench fever as a separate disease has been established. By a coincidence, at the very time when Mr. Thorne was asking his question the paper published in this issue by McNee, Renshaw, and Brunt, officers serving in the R.A.M.C. in France, was on its way to us, for it came into our hands on January 25th. Their investigation shows that trench fever is a distinct specific fever of relapsing type not due to any virus previously known. The relapses may be one or several in number; in either case the characteristic symptoms are headache and pain in the legs and the small of the back.

Trench fever, they find, may be transmitted to others by intravenous or intramuscular injections of the blood as a whole, but not by the plasma or serum alone, whether this be filtered or not. These observations, taken together, prove that the virus is not a "filter passer," and also that it is probably contained within the leucocytes or red blood cells themselves. Not being a "filter passer," it seemed reasonable to expect that the germ, whatever it might be, would be of sufficient size to be detected microscopically, but, though the authors have examined many blood films at all stages of the disease; no

parasite of any sort has so far been detected. Punctate basophilia in the red cells is the only abnormal change that has been noted in the cases. The present position with regard to trench fever is, then, in some respects analogous to that with regard to typhus, as recent researches have shown that the virus in this instance also is not a filter passer, and that the injection of blood will produce the disease in monkeys. From time to time different bacilli have been claimed to be the cause of typhus, but so far none has been generally accepted. It is interesting, however, to note that both typhus and relapsing fever are spread by lice, and it is possible that trench fever is another louse-borne disease. The fact that the disease has occurred only among men who have actually lived in or near the trenches or men constantly in contact with sick and wounded men from the firing line—that is to say, men of the Royal Army Medical Corps—is suggestive.

It is difficult to see how the virus of the disease can get from the blood of one man to another unless it is carried by an insect. Further research might include the possibility of the germ existing in the saliva, urine, and other excretions, and we have no doubt that in the course of the investigation other means of trying to cultivate it than those apparently hitherto employed will be tried; it is possible that it may be an organism that does not grow in bile salt broth. Some protozoa will live and thrive in the water of condensation of haemoglobin agar, and delicate bacteria will grow and multiply on its surface readily as well.

It is clear that the study of this interesting disease has been very difficult, as has been the case with others in which no definite organism can be found by ordinary bacteriological methods, and great credit is due to Captain McNee and his colleague for the great amount of light they have thrown upon an intricate problem. It is a great advance that, as is pointed out by Colonel Sir Wilmot Herringham in a note prefacing the article, trench fever can now be defined and isolated from a mass of cases of obscure fevers.

No doubt until clinical suspicions were aroused cases were confounded, not wholly without reason, with such protean disorders or symptoms as influenza, neuritis, myalgia, or even rheumatic fever. It is wholly distinct from enteric fever, though naturally, as Sir Wilmot Herringham justly says, that disease should be suspected until its presence has been disproved where armies in the field are concerned. The fever is still occurring among the British forces in France; and as it is a fruitful source of invaliding, the results of further investigations into its cause and mode of transmission will be awaited with interest.

"PATENT MEDICINES."

THE Medico-Political Committee reported to the meeting of the Council of the British Medical Association on January 26th that it had addressed a communication to Sir Henry Norman, M.P., Chairman of the Select Committee on Patent Medicines, conveying the resolution by which the Annual Representative Meeting, 1915, placed on record its satisfaction with the recommendations of his committee, and instructed the Council, as soon as it considered the time opportune, to take all necessary steps to press for legislation on the lines of the report. The letter went on to express the hope that when normal times returned the Association might have his support and influence in urging on

the attention of Parliament the very serious evils which the report disclosed, and the necessity for dealing with them drastically on the lines suggested therein. Sir Henry Norman, in his reply, said that when a return to normal times arrived he would be wholly at the service of the Association for any further help it was in his power to give. The Council of the British Medical Association, in its annual report¹ last year to the Representative Meeting, expressed the opinion that a report so radical in its scope and so satisfactory in its nature, coming from such a source as a Select Committee of the House of Commons, thoroughly justified the action the Association had taken in regard to secret remedies, but added that the present was obviously not the time at which the Government could be pressed in regard to the matter. It considered that the first favourable opportunity should be taken, and the Medico-Political Committee is anxious that medical practitioners should obtain the report and study it carefully, as the question will require energetic treatment at the earliest opportunity. Reports of the evidence, taken by the Committee during its thirty-three public sittings, were published regularly in the *BRITISH MEDICAL JOURNAL*, beginning on May 18th, 1912 (p. 1140), and terminating on June 21st, 1913 (p. 328), the Committee having closed its public sessions on June 12th, 1913. The report itself costs 3d.; the large blue book containing both the report and the full text of the evidence costs 6s. 7d. Either can be obtained through any bookseller.²

The findings of the Committee and its recommendations were published in full in the *BRITISH MEDICAL JOURNAL* of August 29th, 1914 (p. 404), and have been discussed on several occasions since.³ The general effect of the findings was expressed in two of them, where it is said that "the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of impropriety, is practically uncontrolled in this country," and it is added that this is an intolerable state of things, to remedy which new legislation is urgently needed in the public interest. The Committee outlined the legislation it considered necessary. One of its recommendations was that in the case of every medicated wine and every proprietary remedy containing more alcohol than that required for pharmaceutical purposes, the law should require the proportion of alcohol contained in it to be stated on the label.

Another was that the advertisement and sale (except by a doctor's order) of medicines purporting to cure certain diseases should be prohibited. Among the diseases to which it was considered this should apply were cancer, consumption, diabetes, paralysis, locomotor ataxy, epilepsy, Bright's disease, and rupture (without operation or appliance). The Committee recommended that Parliament should make it illegal to change the composition of a remedy without notifying the Government department proposed to be set up of the proposed change, and that fancy names for recognized drugs should be subjected to regulation. It also suggested legislation which would make the practice of what is called "following-up" illegal. Under this system, which we believe originated in America, when once the vendor gets into communication with some person, he or she is plied with a series

of letters inviting correspondence, and probably, eventually, recommending other remedies for other disorders from which the person addressed may be induced to think he or she is suffering. Many instances of this plan will be found in the two volumes, *Secret Remedies* and *More Secret Remedies*, published by the Association.⁴

The Committee also recommended that it should be made illegal to use the name of a fictitious person or a fictitious testimonial in connexion with a remedy, or to publish a recommendation of a secret remedy by a medical practitioner unless his or her full name, address, and qualifications were given.

The State department for dealing with secret remedies proposed to be set up should, the Committee thought, be controlled in the meanwhile by the Local Government Board. One of its duties, it was recommended, should be to keep a register of manufacturers, proprietors and importers of patent, secret, and proprietary remedies, who should be required to obtain a certificate. Before granting this certificate the department would require the applicant to supply it, among other information, with a complete statement of the ingredients and proportions of the same in every such remedy. The Committee also recommended the establishment of a special court or commission to be set in motion by the President of the Local Government Board, which would have power to permit or prohibit in the public interest, or on the ground of non-compliance with the law, the sale and advertisement of any patent, secret, or proprietary remedy or appliance.

With regard to the amendment of existing legislation the Committee recommended that the Indecent Advertisements Act should be amended on the lines of Lord Braye's bill, and that the Stamp Acts should be consolidated and amended to remove the numerous existing anomalies and unreasonable exceptions. It did not recommend the abolition of the patent medicine stamp duty, and this seems to be the only part of the report which has hitherto had any effect on the Treasury. It will be remembered that in the Budget introduced on September 21st last the Chancellor of the Exchequer proposed to double the patent medicine duty of 1½d. in the shilling, and expected an addition to the revenue from this source in a full year of £250,000. The suggestion greatly amused the House of Commons, but as we observed on October 2nd last, it may well be asked whether it is statesmanlike to palter in this way with an evil which must cost the country in loss of health and life tens of millions a year.

There can be no doubt that the recommendations of the report are worthy of the very serious consideration of the profession, so that it may be prepared to express definite opinions upon all of them when the time comes for Parliament to deal with any proposals for legislation which it may be thought proper to put forward. The proceedings of the Select Committee themselves afford ample proof that restrictive legislation will be met by strong opposition from certain quarters—certainly from the proprietors of secret remedies, possibly also from the owners of some newspapers. It is conceivable that the proprietors might not have any strong objection to the establishment of a Government department to which they would be required to disclose the ingredients of their preparations, and from which they might hope to receive a certificate permitting them to trade. We could even imagine that they would welcome legislation which might seem to give to their trade

¹ SUPPLEMENT to the *BRITISH MEDICAL JOURNAL*, May 8th, 1915, p. 185.

² Report from the Select Committee on Patent Medicines (ordered by the House of Commons to be printed, August 4th, 1914). Price 3d. Report from the Select Committee on Patent Medicines, together with the Proceedings of the Committee, Minutes of Evidence, and Appendices. (Price 6s. 7d.) Either can be purchased, directly or through any bookseller, from Wyman and Sons (London), H.M. Stationery Office (Edinburgh), E. Ponsonby (Dublin).

more definite public recognition than through the operation of the Stamp Acts it already enjoys. It is very questionable indeed whether such legislation would be of any value unless the same Act contained a clause on the lines outlined by the Committee forbidding the advertisement and sale of secret medicines purporting to cure such diseases as cancer, consumption, and the others enumerated. We should also regard the provisions suggested as to the regulation of the trade in medicated wines as of great importance from several points of view, but it will be observed that the Committee does not go beyond recommending a provision requiring the proportion of alcohol contained in any such wine to be stated on the label. Legislation prohibiting the publication of advertisements likely to suggest that the medicine sold is an abortifacient, would, if enforced, put an end to a public scandal. The suggestion that the publication of a recommendation of a secret remedy by a medical practitioner should be forbidden by law unless his or her full name, qualifications, and address are given would no doubt have a deterrent effect, but should be extended by making it penal to publish testimonials purporting to be given by medical practitioners long since dead. These are some of the provisions urgently needed, and the Select Committee considered that none of them would inflict injustice upon any patent or proprietary medicine or appliance.

THE INTRODUCTION OF CINCHONA TREES INTO INDIA.

SIR CLEMENTS MARKHAM, who died on January 30th in his 68th year as the result of accidental burns, succeeded in introducing cinchona trees into India after several other attempts had failed. In 1852, the year in which he retired from the Royal Navy, he paid a two years' visit to Peru, and published a book on his travels in 1856. A few years later he again went to Peru at the request of the Secretary of State for India, to superintend arrangements for the collection of cinchona plants to be introduced into India, and we are very glad to have the opportunity of publishing the following interesting note by Sir George Birdwood, M.D., K.C.I.E., relating the story of the arrival of the plants in India and the early stage of the introduction of the cultivation of cinchona into that country. "I have," he writes, "none of the official documents by me for the verification of the following particulars of the introduction by Sir Clements Markham of the cinchona trees of South America into India, but you may rely on their accuracy as a general statement, as I happened to be the official who, under the direction of Sir George Russell Clerk—'George Clerk of Umballa'—received Sir Clements, and his large nursery of young cinchonas, on his arrival in Bombay in 1860, and assisted him in taking them on to the Nilghiri Hills in Southern India, where he placed them in charge of Mr. MacIvor, one of the most skilful arboriculturists then in India, to whom Sir Clements also entrusted the subsequent supplies of young cinchonas collected under his instructions in South America by Messrs. Spruce and Pritchett. They all flourished wonderfully under MacIvor, who was able within a few weeks to send out stocks and seeds for cultivation in Ceylon and Sikkim. Earlier attempts had been made by Boyle and Weddell and Falconer to naturalize the cinchonas in India, but all had failed; and it was Sir Clements Markham's choice of the species of cinchonas (in the which he was advised by Sir Joseph Hooker) and of the Nilghiris for their new habitation (in which he was encouraged by Sir George Clerk while still Permanent Under Secretary of State for India, 1858-60) that secured the success of his arduous adventure—one of the greatest of the blessings conferred by 'the British

Raj' on the malaria-stricken peoples of India. The cinchonas grown by MacIvor were *Cinchona Calisaya*, *C. micrantha*, *C. lancifolia*, *C. nitida*, *C. officinalis*, *C. Pahudiana*, *C. peruviana*, and *C. succirubra*. *C. Calisaya* has, I believe, proved the most successful on the Nilghiris."

ALCOHOL AND THE SOLDIER.

THE Academy of Medicine in Paris has drawn up an appeal to soldiers warning them with regard to alcoholic beverages. The preamble and the first three paragraphs were adopted without discussion, but the fourth paragraph, in which a distinction is drawn between distilled and fermented beverages, was discussed at some length. As originally proposed, the paragraph contained after "aids digestion" the words "This is true"; these were struck out. The original draft did not contain the words in the second part of this paragraph as to the *petit verre* after meals, and originally stated that fermented beverages might be useful. The following is a translation of the text of the leaflet:

Soldiers—Beware of Alcohol.

Those who, like you, are exposed to exhausting labour, to perilous enterprises, and to strong emotions, are ever inclined to look to alcohol as a stimulant and a comforter, and to seek for it in the tavern as a distraction from the monotony of cantonment and garrison life.

It is therefore well that you should know what use you may make of alcohol without impairing your health.

Certain errors about alcohol are widespread.

1. It is said to *give strength*. This is not exact. The truth is, it gives a false spurt of short duration, but a grave diminution of strength never fails to follow this excitement. Thus alcohol takes away more strength than it gives.

2. It is also said that alcohol *gives warmth*. This is true for a few minutes, but the feeling of warmth which spreads over the limbs after a nip of brandy is delusive and is soon followed by a lessening of warmth and strength. Men who take nips are far more subject to chills and to diseases to which men at the front are liable.

3. It is further asserted that in the form of a "*pick-me-up*" alcohol stimulates the appetite. This is quite wrong. It would be difficult to produce any man whose appetite had ever been really stimulated by a "*pick-me-up*." These *apéritifs*, habitually taken, lead without fail to disease of the stomach, liver, and mind.

4. Lastly, it is maintained that alcohol *taken during meals* as wine, beer, or cider *aids digestion*. An important distinction must be drawn between "*distilled*" liquors like brandy and "*fermented*" liquors such as wine, cider, and beer. Alcohol is altogether noxious. The *petit verre* after meals should only be taken on rare occasions. Fermented liquors, on the other hand, may be drunk subject to two conditions. They must be consumed in great moderation, which, as regards wine, should never exceed 1 litre (a pint and three-quarters) in twenty-four hours and *only at meals*.

THERAPEUTICS OF RADIUM.

THE first report of the Manchester and District Radium Institute, dealing with the cases treated during 1915, is marked by great moderation. The Institute has its head quarters in a series of rooms in the basement of one of the buildings of the Royal Infirmary, and is admirably adapted for the work it has to do. It is a complete department, with all the usual waiting, dressing, and consulting rooms, and separate cubicles for the actual treatment. At present the physical laboratory is small, but it is probable that a more suitable laboratory, more adequately equipped, will be added. A large quantity of radium is at the disposal of the staff, and as many of the cases have to be treated at other hospitals than the infirmary, a considerable part is used for the purpose of collecting and using the emanation. The director, Dr. Burrows, points out that the treatment of cancer in its various forms has been so far the chief work of the department, and he wisely warns the general public not to take an exaggerated view of what radium can accomplish in this direction. In dealing with this aspect of the work it is worth while to lay stress upon the point that only inoperable cases of malignant disease are accepted for this treatment. When we consider and criticize the treatment from this

limited point of view, it is obvious that cures must of necessity be few and far between. The time may come when it will be justifiable to undertake the radium treatment of malignant disease in its earlier stages, that is, before it has become inoperable, but this time has not come yet. This may possibly be due to the facts that exact methods of application, exact dosage, etc., are as yet imperfectly understood. When we consider the occasional unexpected and extraordinary effects of radium in an apparently hopeless case, it is impossible to shut our eyes to the latent possibilities of both radium and x rays when the measurement of dosage, and the rationale of application, in the future, are better understood. The Manchester clinic has advanced the method of treatment by emanation, and the burying, by means of hollow needles, the emanation in the centre of tumours. This method, introduced by Stevenson and Joly, is, at the present time, that which seems to promise the best results. Dr. Burrows has a modified needle, in which the solid-pointed end, and the eyeleted end, can be screwed on and off. This means that the central portion containing the emanation can be prepared, and the two ends then fitted on to it for introduction into growths. It is of interest to note that in the general summing up of the methods of technique stress is laid on the point that, in introducing the tubes into a growth, just as much care should be adopted as to aseptic technique as in general surgery. We cordially agree with this, but we do not agree with the suggestion that large incisions should be made through the skin for the same purpose. The sound principle seems to be to make the smallest possible incisions, as it is of importance not to open up lymph channels and so encourage general dissemination of the growth. The general observations dealing with filtration and dosage are useful, and the caution against large dosage with long exposures and slight filtration, liable as it is to lead to sloughing and necrosis of tissues, is not out of place. Special attention should be called to the remarks on the treatment of the recurrent nodules after an operation for cancer of the breast; great care must be taken not only in the burying of radium, but also in its external application; a permanent ulcer is easily produced. The report states that the treatment of carcinoma of the cervix uteri by radium has, on the whole, given good results. The value of this statement entirely depends upon what is understood by the phrase "good results." Temporary amelioration in the local condition, diminution of haemorrhages, cessation of putrid discharge, often mean that the patient's general condition is for the time markedly improved, and in this respect the immediate result is good, but the term "good result" must not be taken to indicate that anything in the nature of cure is likely to result. Many surgeons, after a trial of radium in these cases, are of opinion that equally good temporary results can be brought about by scraping and the use of the cautery. During the year 519 cases were dealt with in the department, and the concluding portion of the report gives tables of the cases and the results obtained.

BOVINE TUBERCULOSIS IN MAN.

A REPORT on a continuation of the research in the pathological laboratory of the Local Government Board into the types of tubercle bacilli occurring in tuberculous disease of bones and joints has been published by Drs. A. Eastwood and F. Griffiths in the *Journal of Hygiene*.¹ It deals altogether with specimens from 313 cases, but in 5, though there was disease of bone or joint, the material was obtained from other sites, and these have been rejected in compiling the statistics, as have also 47 cases in which the results were negative. This left 261, and in 55 of these, or 21.1 per cent., the bacilli were of the bovine type. Of the 261 patients, 155 were under 10 years of age, and the percentage of the bovine type in

them was 29.0. Under 5 years of age it was practically the same (29.8). In the 106 cases over 10 the percentage of the bovine type was 9.4. Only 3 were over 16, the ages being in two cases 17 years, and in one 22. In 10 cases out of the 261, the bacilli were atypical, and their source cannot at present be stated. The medical officer to the Local Government Board, in a brief comment on this report (published in his report to the President), observed that the investigation affords evidence that in the areas from which the cases were derived tuberculous bone and joint disease in human beings is more frequently caused by the human than by the bovine type, although the latter is responsible for an important percentage—a fact which, it is admitted, affords additional proof that cow's milk is responsible for producing much tuberculosis in man. The parts of the country from which the specimens were derived are not anywhere stated, but it is to be presumed that they were all from England. In the investigation reported by Eastwood and Stanley Griffiths to the Local Government Board in 1914 the proportion of the bovine to the human type was 19 to 93, so that the percentage in the new series is appreciably higher. It will be remembered that in a similar study carried out in Edinburgh Dr. John Fraser² found the bovine bacillus in 41 out of a total of 70 cases investigated, the human bacillus in 26, and both types in 3. The cases he examined were all under 12 years of age, and he made the very significant observation that of 28 children, all 3 years old or under, the bovine organism was present in 23, and the human in 5 only. He also brought out a most interesting point with regard to the family history. In 21 instances there was a definite history of pulmonary tuberculosis in some member of the family in which the child lived, and in 15 of these children the type of bacillus present was the human. In 52 cases there was definitely no family history, and in 43 of these children the bacilli was of the bovine type. Dr. Philip Mitchell,³ also working in Edinburgh, found that in the tuberculous cervical glands of 72 children the bovine type of bacillus was present in 65, and the human in 7 only; in 27 children under 3 years of age the bovine type occurred in 25, and the human only in 2. In a subsidiary investigation on the type of tubercle bacilli found in tuberculosis of the genito-urinary tract Eastwood and Griffiths found the human type in 14 and the bovine type in 3. These three cases were affections of the kidney in persons aged respectively 25, 19, and 20 years.

THE PROTECTION OF THE X-RAY OPERATOR.

At the February meeting of the Röntgen Society a discussion was opened (to be continued at the March meeting) on the subject of the protection of the x -ray operator. Dr. Sidney Russ pointed out that while x -ray dangers were becoming less formidable owing to the widening knowledge of them, there was still a good deal of uncertainty because the modern outfit furnished perhaps fifty times more energy than the outfit of ten years ago. It would be a great advantage if effective protection could be obtained without resort to legislation, for of all the methods available for ensuring it legislation was likely to be the least popular and the least convenient. In the course of the discussion Dr. G. H. Rodman suggested that the General Medical Council be asked to include x rays in the medical curriculum, so that before qualification the student should be as fully acquainted with the dangers of the x -ray tube as he was with the dangers of strychnine. Sir James Mackenzie Davidson mentioned that while doing screen work he placed a thick lead barrier round the tube; the observer, standing completely behind this barrier, was enabled to see the screen image reflected in a fine plane glass mirror. Dr. Fred. Bailey, of Brighton, said that it was his practice

¹ January, 1916.

² BRITISH MEDICAL JOURNAL, April 12th, 1913, ii, 760.

³ Ibid., January 17th, 1914, p. 125.

to have a large screen running on castors, the upper third of it being of lead glass. His tube was enclosed in a large lead glass bulb, and under such conditions as these it did not seem probable that any x-rays were directly received by the operator. There remained the ionization of the air, which was quite possibly a source of danger, and Dr. Reginald Morton confessed that after an afternoon spent in x-raying a number of cases, he suffered from a severe sense of fatigue. The ventilation of the room did not appear to make matters much better. Dr. W. Harwood Nutt said that the effects of atmospheric ionization might be prevented by ventilating the room efficiently, having not one but two ventilators, so that a constant current of air was passing from entrance to exit. Some x-ray workers were returning from the seat of war with very bad ulcers on their arms and hands, and for his own part he did not believe that any man could protect himself adequately unless the tube itself, in distinction from the worker, were shielded. Dr. N. S. Finzi gave an interesting experience which seemed to show the negligible character of stray radiations spread over a period. One of his assistants had placed an enclosed Sabouraud pastille on the front of his apron and another on the back. The pastille in front was found to have turned to the "B" tint after about two weeks' hard work (x-raying every morning and eight afternoons), but the pastille on the back of the apron was still unturned after six weeks, and it did not seem likely that a full dose would be received there within a shorter period than three months. Such a dose, even though continued over a long time, could scarcely do the operator very much harm. Dr. Bailey stated that he had noticed a certain amount of anaemia among persons constantly receiving x-ray treatment, and Dr. Russ said that one of the hidden dangers of x-rays was undoubtedly the blood change brought about. In the cases investigated the red cell content was invariably shown to be below the normal, and in many cases the white cell content also. The lymphocytes were in almost every recorded case very greatly reduced. As to a cure for x-ray dermatitis, Dr. Rodman said that his own trouble, including split nail, had practically cleared up after he had followed the plan of avoiding the x-ray tube as much as possible and exposing himself to sunlight and fresh air.

MEDICAL WORK OF THE LOCAL GOVERNMENT BOARD

The report of the Medical Officer to the Local Government Board for 1914-15 is a much smaller volume than usual. The first part is devoted to an account of the steps taken by the Board some time after the outbreak of the war to meet the emergencies which had arisen. During the autumn of 1914 and in the first three months of 1915 twelve medical inspectors were engaged almost exclusively in visiting districts occupied by troops. They discussed local difficulties, and in numerous instances more complete co-operation of civil and military authorities than had previously been practicable was secured. A similar system of co-operation between the naval medical authorities and the local authorities was arranged as far as naval camps, dépôts, and billets on shore were concerned. From August onwards a system of internotification of infectious diseases was arranged between civil and military medical officers. In the following month the War Office issued for confidential use a weekly statement as to various infectious diseases among the troops in different commands. In most centres military disinfecting apparatus was provided, but the civil authorities also carried out disinfection on a large scale for the troops. Another task undertaken by the Board was the protection of food supplies, the Board's offer to the War Office of the loan of inspectors of foods being accepted. Steps were taken to ascertain the place of preparation of food materials, and the M.O.H. of each district was asked to keep the preparation of these foods under close observation. During the

year under report there was no large outbreak of enteric fever, and though there was an enormous rise in the number of men under arms, there was no corresponding rise in the incidence of this disease. Of other infectious diseases measles showed a decline from 10,644 deaths in 1913 to 9,144 in 1914. It is a striking fact that this figure was barely exceeded by the deaths in 1914 from small-pox, diphtheria, enteric and scarlet fever combined, the total for these four diseases being 10,450. One of the most interesting features of the report is the section dealing with tuberculosis. It is a most deplorable result of the war that the important schemes for dealing with the many aspects of this disease had not matured when the call for economy and retrenchment had to be obeyed. Before the war six medical inspectors were employed in the tuberculosis service. From August, 1914, the work has approximately occupied the full time of two inspectors. The erection of institutions for the tuberculous has in many cases been deferred. Arrangements, it is stated, have been made for the treatment in residential institutions of uninsured soldiers suffering from tuberculosis, but details are not given. It is said that the notification of non-pulmonary tuberculosis is defective, owing, it is thought, to the failure of medical practitioners always to realize that the notification of this form of tuberculosis may reveal sources of infection and undesirable housing and industrial conditions. The Board asks medical officers of health to communicate with practitioners who fail in this respect. On June 26th, 1915, tuberculosis officers had been appointed in the proportion of one for 145,000 persons in the administrative counties, and one for 110,000 in the county boroughs. By the end of that month about 30 per cent. of the tuberculosis officers had accepted military service, temporary arrangements being made for carrying on the work in their absence. The number of sanatoriums and allied institutions increased from 104 in July, 1914, to 120 in June, 1915; and the number of beds from 5,398 to 6,496. In July, 1914, about 25 per cent. of all the beds in these institutions in this group were provided in institutions belonging to local authorities; in June, 1915, this percentage had risen to 32. It is satisfactory to find that the Board has realized the desirability of treating children and adults separately as far as possible. The drawbacks of mixing children with adults are many and great. The Board has also accepted the view that for the satisfactory conservative treatment of tuberculosis of bones and joints a separate institution is desirable. The importance of making suitable arrangements for education in institutions receiving children of school age is also recognized by the Board, which has decided not to approve any children's institution in which the requirements of the Board of Education with regard to education are not satisfactorily met. The section of the report dealing with the auxiliary scientific investigations is brief. We refer elsewhere to the work done by Drs. Eastwood and Griffiths, but it may be noted here that a comparative study by Dr. Gauvain at the Lord Mayor Treloar Cripples' Home, of the reactions to human and bovine tuberculosis in cases of tuberculous disease of the bones and joints, appears to show that it is not possible to discriminate between infection by the human and bovine type of bacilli by means of the von Pirquet test. To a memorandum by Dr. Newsholme on health visiting and on maternity and child welfare centres we hope to refer on another occasion. One of the appendices contains a voluminous report by Dr. Bruce Low on typhus fever in recent years, giving an account of the incidence of the disease in various countries.

CIVIL HOSPITAL STAFFS OF MILITARY AGE.

A few weeks ago we gave some account of a difficulty which had been raised by certain members of the committee of the Worcester Infirmary in accepting an arrangement proposed by the medical staff for carrying on the work of the infirmary during the war. Four members of

the staff and the qualified house-surgeon had joined the R.A.M.C., but the remaining members of the staff had undertaken to carry on the work, arranging that a member of the honorary staff should sleep at the infirmary in rotation for some days. Subsequently the honorary medical staff accepted an offer made by three medical men in the city to give their assistance as required. This did not satisfy some members of the committee who were anxious that the offer made by a fourth doctor should be accepted. The committee by a majority accepted the offer, but the members of the consulting and acting staff subsequently sent a round robin declining to work in the infirmary with any man of military age appointed temporarily to take the place of their colleagues who had joined the army. If we understand aright what happened at a recent meeting, the committee took no definite action on this letter, the medical staff being left to ask for assistance as and when required, but the vice-chairman, Mr. Harris, took the opportunity of making an attack upon the staff, and indeed upon the profession generally. Mr. Harris worked himself up to such a pitch of excitement that he proposed to have the difficulty he anticipated settled under the provisions of the Defence of the Realm Act. This wild suggestion did not commend itself to the committee, but the attitude of mind disclosed is curious, though not very unusual; outbursts of the kind are not by any means all directed against the medical profession. There are quite a number of people who get an obsession of the sort against certain other classes of their fellow citizens. There are some—and they seem to be very numerous just now—who look upon all lawyers as sons of Belial; others who regard clergy of all denominations with particular aversion; and others, again, who can never see a brewer without looking for horns and a tail. It seems to be a phase of the mental state on which the Germans sought to found their now discredited so-called science of *Völkher-psychologie*.

EDUCATIONAL UNREST.

THE letter from Sir Philip Magnus, the representative of the University of London in the House of Commons (published in another column), will, we feel sure, attract the attention of all those among our readers who are interested in the development of secondary and higher education in this country. Before the war there was in some influential quarters a tendency to blind admiration of German educational organizations, and a reaction had already begun. It has been greatly accelerated by the revelation, through their conduct in Belgium and other districts overrun, of the low ethical standard which has been produced under the German system. But the choice does not lie between a slavish imitation of Germany and the maintenance unchanged of our own system, in spite of the patent faults disclosed. It is a grievous thing to find young men of high attainments going out into business and politics without any knowledge of natural phenomena and how they may be investigated, explained, and applied to the advancement of knowledge and industry. There can be no reason why this particular fault should not be corrected without destroying the valuable characteristics of English schools and colleges. As the Vice-Chancellor of the University of Leeds said over a year ago, "In the difficult days of social readjustment which will follow the war there will be more need than ever for variety of experiment, for variety of educational tradition, and for variety of responsible initiative." "Freedom," he went on, "from the iron band of State control allows teachers and pupils the training in individual responsibility which develops and fortifies character; and the higher kind of freedom, though indocile to external pressure, realizes itself in willing subordination to the common good." It is, we believe, with some such thoughts in his mind that Sir Philip Magnus appealed to the Prime Minister to take steps now

to see that the scheme which the Board of Education has in hand shall be so moulded that it shall not act as an iron band to restrict and deform the natural growth of education in this country.

MILITARY HOSPITALS' JOURNALS.

THE *Craigleith Hospital Chronicle* continues its interesting and amusing way. The issue for February is the fourteenth. Many of the contributors are or have been connected with the 2nd Scottish General Hospital, and the editor is fortunate to have on his staff some person or persons who can draw most effective initial letters and tailpieces. Running through recent numbers is a series of articles entitled "The Story of Some Scottish Regiments," by Dr. J. A. MacDougall. The last two dealt with are the Black Watch and the King's Own Scottish Borderers. The articles are illustrated by drawings of the regimental badges and of the medals and clasps which men of the regiments have been entitled to wear. As was said in an effective little article in a recent number of the *Gazette* of the 3rd London General Hospital, Wandsworth, though men pass away the regiment goes on. The editor of the Wandsworth magazine, like his brother in Edinburgh, is fortunate in having some very excellent artists on his staff, and Mr. Nevinson, by his drawings of the arrival of an ambulance at night, a month or so ago, and of the receiving hall in the issue for February, almost reconciles us to Futurist art. Nobody, from the C.O. to the ward orderly, seems safe from caricature, but it is all very good-natured. Some day sets of these periodicals will be valued curiosities, and already Dr. W. W. Keen, the veteran surgeon of Philadelphia, is collecting them for presentation to the great library of the College of Physicians in that city. It is also hoped to preserve them in the library of the British Medical Association, but the first number of the Wandsworth *Gazette* is missing, and the editor informs us that it is out of print. The same has happened to the first and second numbers of the *Craigleith Hospital Chronicle*. Unfortunately our file of the *Craigleith Hospital Chronicle* is still more incomplete, as all the numbers of the first volumes are missing—in fact, only the ninth, twelfth, thirteenth, and fourteenth numbers are in hand. Any one who has spare numbers which he does not propose to preserve will be doing a good deed by sending them to us for preservation.

CEREBRO-SPINAL FEVER.

IT will be within the recollection of many of our readers that in the course of the outbreak of cerebro-spinal fever among the civil population of Salisbury last winter prophylactic inoculation was employed on a considerable scale by representatives of the Lister Institute working in co-operation with the medical officer of health. A preliminary note on the results was communicated by Dr. Fison, M.O.H. for Salisbury, to the Royal Sanitary Institute, and it appeared that the method had been productive of some decided advantages. In view of the great practical importance of the subject it is very desirable that further work should be undertaken. The authorities of the Lister Institute are anxious to hear from any medical officers of health who may have to devise measures for dealing with local outbreaks of cerebro-spinal meningitis with a view to co-operating with them, as it is not improbable that protective inoculation may prove the solution of a difficult administrative problem. Inquiries should be addressed to the Director, Lister Institute of Preventive Medicine, Chelsea Gardens, S.W.

Two convoys of tuberculous prisoners—French and German—arrived in Switzerland ten days ago. The Germans coming from Lyons, and numbering 100, were sent to Davos; the French, numbering 101, coming from Constance to Leysin, where they were welcomed by the authorities.

THE WAR.

WAR NEPHRITIS.

(From a Correspondent in Northern France.)

Cases of war nephritis continue to be seen in considerable numbers, but there is no really fresh development to record in connexion with this particular source of wastage. Certain points have, however, been emphasized by the experience of the past six months, and there is also perceptible some degree of change in the general medical attitude towards the prognosis of these cases. After two marked swings in either direction, the pendulum is now stationary and fairly perpendicular.

In civil life acute nephritis occurring in young adults, and independently of any other apparent disorder, is often fatal, and at the best runs a very protracted course, months elapsing before the albumin disappears. On this analogy the initial view taken of war nephritis was grave, but a difference between the two conditions was very soon noted. In case after case the dropsy and albumin disappeared within a fortnight or three weeks, and all direct evidence of kidney mischief vanished rapidly. The belief then arose that war nephritis was a disorder *sui generis*, and not likely to affect permanently the well-being of the individual concerned, or to do away with his military value for more than a month or two at the most.

This was the position of affairs about the date of the appearance of the first note on the subject (July 17th, 1915, p. 109). Present views are somewhat different. It is now thought that the prognosis should be guarded in respect of the ultimate effect of the disorder on the future of any given individual concerned, and that the previous belief as to the comparative unimportance of the disorder from the point of view of military efficiency was mistaken.

It is true that the case-mortality continues to be very low, and it is also true that as soon as the initial anasarca has disappeared—and this, as a rule, is within a fortnight—patients generally regain an appearance of well-being. It is also true that within three or four weeks albumin, casts, and blood cells generally disappear entirely from the urine. But this is not always the case, and sundry reports from home suggest that in certain instances, at any rate, evidence of continued or renewed kidney trouble may be found at a much later date.

As to other points, the experience of the past summer and autumn has confirmed the belief that though exposure may aggravate an existing case, it is not in itself an originating cause. The belief is also confirmed that though a certain number of the patients may be persons in whom the nephritis is merely a recrudescence of a pre-existing disorder, the great majority of cases occur in individuals who have been perfectly healthy in regard to their renal systems and all other respects. Nothing, in short, has occurred to disturb the view that the condition is a new disease in the sense that as a whole its phenomena do not correspond precisely with any symptom-complex previously familiar to clinicians. No pathologist of my acquaintance is disposed to be very confident as to its etiology, or has put forth any view which, from a laboratory standpoint, brings the condition entirely into line with the idiopathic acute nephritis of civil life. Consequently "war nephritis" is about as near as one can get in the way of a specific label for the condition.

Objectively, facial oedema with some elevation of temperature is found to be the most conspicuous phenomenon in early cases; subjectively, headache, aching pains, and especially a feeling of breathlessness.

With these early subjective symptoms a certain degree of bronchial catarrh sometimes coexists, but it is never sufficient to explain the breathlessness mentioned. A history of the latter may be obtained in practically all cases, and it is probably to be attributed to an increase in the acid contents of the blood. No attempt has been made as far as I know to examine the blood from this point of view, but the causative connexion between acidosis and breathlessness is well recognized in renal disease of civil life.

Another feature is an increase in the blood pressure. This has been found to be invariably present when the point has been tested at the hospital in France which has received a large proportion of all these cases, and a series

of pressure records shown me by one observer (Captain Abercrombie) indicated that in respect of the systolic maximum a rise up to 200 mm. is by no means rare.

The breathlessness is, however, not an enduring feature, and the blood pressure seems to fall rapidly under the influence of rest in bed and a fluid diet. The same treatment also quickly converts an initial oliguria into polyuria, and the output of albumin and blood soon begins to lessen. The latter is at first usually present in perceptible quantities in the urine, and is always to be found by the microscope. Febrile symptoms usually disappear within ten days or so of their first appearance, and the patients seem to be generally sufficiently recovered to be sent home within three weeks of their arrival at a base hospital—that is to say, within a month of the time they first began to feel unwell.

Meantime, however—that is to say, in the stage of acute illness—comparatively few patients fail to exhibit some of the minor phenomena of uraemia, for example, generalized headache, or sleeplessness, or vomiting, and actual fits are not very uncommon. Nevertheless, right from the beginning I have not heard of more than three or four deaths, and only one of these seems to have been a typical case. In the rest there was evidence of pre-existing renal disorders, and even in the typical case the tendency towards death seems to have been increased by a large pleural effusion of renal origin.

In regard to the etiology of the disorder, there are those who favour the idea of a streptococcal infection, but direct evidence is lacking, and the subacute tonsillar inflammation which is so common in disorders of streptococcal origin figures with comparative rarity in the history of war nephritis. The grounds for holding it to be due to infection by *B. coli* seem even less assured. Association of the condition with intestinal troubles does not appear to be common, and though *B. coli* may be identified in the urine, the frequency with which this occurs seems to diminish with the care taken to exclude from the count cases in which cystitis coexists. Commonly, indeed, the urine is absolutely sterile.

On the whole, therefore, it seems not improbable that definite evidence will one day be forthcoming in support of the belief that the *causa causans* is a germ capable of passing through a filter and at present unrecognized.

Such a conception is already favoured by clinical observation of early cases. The picture that they then present is fairly constant, and the fashion in which they evolve is in keeping with that of various zymotic disorders of common occurrence. The grouping likewise of some of the cases points in the same direction, though it certainly may be explained on other grounds.

At the beginning it was believed that the cases might possibly be due to some form of metallic poisoning—an obvious possibility, in view of the fact that tinued rations are often consumed by the troops—and consequently hundreds of specimens of urine were tested by expert chemists. Search, however, failed to afford any support for the suggestion.

Finally, it should perhaps be mentioned that since most of the water used by the troops for drinking purposes is subjected to treatment by hypochlorites, there are those who mutter darkly as to the effect of a possible idiosyncrasy to minute quantities of chlorine; correspondingly there are others who dilate upon the circumstance that very few cases have been observed among Indian troops that are non-meat eaters. I am told also that they are immune to scarlet fever, but on none of these latter points have I any assured information.

THE ORGANIZATION OF A FRENCH "HÔPITAL DÉPÔT."

THE "Hôpital Dépôt" is in reality a centre where wounded or sick soldiers are classified and distributed. All the hospital formations of the district send their convalescents to this central dépôt as soon as the state of the latter is such either that they no longer require medical attention or are more or less permanently unfitted for military service. There is a large dépôt of the kind at Aix-les-Bains to which convalescents are sent from an extensive district comprising Chambéry, the valley of the Isère, La Maurienne, Montiers, Bourg St. Maurice, Brides-les-Bains, Les Marches, Challes, etc.

On their arrival at the Hôpital Dépôt the convalescents are examined and distributed according to their state of health as (1) "fit for service" or "fit to return to the front," in which case they are returned to their regimental dépôt for reincorporation; (2) convalescents who are recommended for a furlough of one or two months or more, according to circumstances; (3) for "réforme" (discharge), according as the infirmity has been contracted in the service from operations of war or the disease is the consequence of constitutional predisposition, in which case the discharge does not carry a pension; (4) men whose wounds have diminished their military value, but who are nevertheless capable of rendering service elsewhere than at the front—these are drafted into the auxiliary services; (5) patients suffering from diseases of the organs of special sense, or whose wounds have left infirmities calling for orthopaedic measures—cases of disease of the nervous system, etc., are classified at the Hôpital Dépôt and dispatched to special institutions; (6) wounded soldiers whose disablement constitutes the base of a claim for immediate discharge and pension. These cases are inquired into by a medical commission which reports in due course.

One of the special duties of the Hôpital Dépôt is to classify and complete the medico-military documents that accompany each man on his transfer to hospital and should follow him on his peregrinations. These highly important documents contain the data upon which his right to a temporary or to a permanent pension is based. The "billet d'hôpital" is the most important of these documents. The medical officers of the various hospital formations apparently do not grasp the paramount importance of this document and too often omit all mention of serious surgical interventions, as well as details of the original injury. The rectification and completion of this document entails an immense amount of avoidable administrative work. No patient is allowed to leave the Hôpital Dépôt until his papers have been put in order and brought up to date.

We are indebted to Dr. Baradat, Chief Medical Officer for the Aix-les-Bains district, for the information on which this note is founded.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN H. S. MONKHAM, C.A.M.C., of Vegreville, Alberta, killed in action in France on December 2nd, 1915, was second in command of the 3rd Canadian Mounted Rifles. He was born in 1876, and took the degree of M.D. of the Toronto University in 1906.

Captain Edward Herbert Wyand, 16th King's Royal Rifles, killed in France on January 31st, was the youngest son of Mr. F. S. Juler Wyand, and was educated at St. Paul's School and Guy's Hospital. He took the diploma of L.D.S. R.C.S.Eng., in 1901, and served as a dental surgeon during the South African war.

Lieutenant George Dewar, R.A.M.C., killed in action in France, was the son of the late Mr. James Dewar, of Aberdeen, and was 23 years of age. After serving with the colours for a few months' training, he obtained permission to return home to complete his medical studies at Aberdeen University, where he passed his final examination with distinction. He was gazetted a lieutenant in the R.A.M.C., and was almost immediately sent to the front.

Died on Service.

Major Archibald V. Becher, C.A.M.C., of London, Ontario, died at Quebec on December 25th from double pneumonia. He was medical officer of the 33rd Battalion. His brother, Lieutenant H. Campbell Becher, was killed in action at Givenchy.

DEATHS AMONG SONS OF MEDICAL MEN.

Cummins, Harry Jackson, Lieutenant 15th Gurkhas, fourth son of Dr. Ashby Cummins, Professor of Medicine, University College, Cork, killed in the Dardanelles on August 21st, in an attack on Turkish trenches near Sari Bair, aged 26. He was born in Cork, educated at Cheltenham College, and attained the rank of Lieutenant on April 20th, 1911.

Reed, J. Sleeman, Second Lieutenant, 1st Battalion the Buffs, attached Royal Flying Corps, only son of Dr. J. Sleeman Reed, of Gorleston, Suffolk, died in the Cambridge Military Hospital, Aldershot, on January 31st, aged 19, as the result of injuries

received in a flying accident at Farnborough on January 29th. He was educated at Dulwich.

Rieu, Henry, 16th Middlesex Regiment (Public Schools), killed in France on January 29th, was the third son of the late Dr. Charles Rieu, of Woburn Square, and was on the staff of the Merchant Taylors' School. He was 39 years of age.

NOTES.

ANGLO-RUSSIAN HOSPITAL.

THE Anglo-Russian Hospital, formed by a committee of which Lord Cheylesmore is chairman, Sir Starr Jameson vice-chairman, and Lady Muriel Paget honorary organizing secretary, was opened in Petrograd last week. The ceremony was attended by the Empress Marie, sister of Queen Alexandra, under whose patronage the hospital has been formed, and other members of the Russian royal family. The hospital provides 200 beds, and is established in the palace of the Grand Duke Dmitri. The equipment of the hospital—including an operating theatre, x-ray installation and bacteriological outfit—is complete. The staff is as follows: *Commandant and Chief Sanitary Officer*: A. M. Fleming, C.M.G., M.B., F.R.C.S., D.P.H. *Surgeons*: H. F. Waterhouse, M.B., F.R.C.S.; W. D. Harmer, M.C., F.R.C.S. *Physician*: T. J. Horder, M.D., F.R.C.P. *Assistant Medical and Surgical Staff*: C. Gould May, M.D.; M. Gardner, M.D.; H. F. Thompson, F.R.C.S.; A. B. Rosher, M.R.C.S. (bacteriologists); G. A. Jones, L.S.A. (anaesthetist); J. M. Flavelle, M.R.C.S., D.P.H. (radiographer). The committee also hopes to establish three field hospitals in places selected by the Russian military authorities, and the whole movement is intended as a practical sign of British admiration and gratitude towards the Russian people. That this feeling is widespread is shown by the fact that the Dominion of Canada has recently sent £10,000 to the committee to express Canadian appreciation of the valour and heroism of the Russian armies.

HONOURS.

The King has given permission to a number of naval officers to wear various decorations conferred upon them by the Czar of Russia. Among them is temporary Surgeon T. S. Bradburn, R.N., who receives the third class of the Order of St. Anne.

SIR IAN HAMILTON'S DISPATCH.

In the list of officers mentioned in Sir Ian Hamilton's Gallipoli dispatch of January 28th are four medical students of Trinity College, Dublin, who hold or held temporary commissions as combatant officers—namely, Captain R. R. Tobin, 7th Royal Dublin Fusiliers (third-year student), since killed; Captain G. H. Davis, 7th Royal Munster Fusiliers (second-year student); Lieutenant A. L. Gregg, 6th Royal Irish Fusiliers (third-year student); and Second Lieutenant F. G. Heuston, 6th Royal Irish Fusiliers (fourth-year student), since killed.

THE INDIAN SOLDIERS' FUND.

The second report of the Indian Soldiers' Fund deals with the period from April 1st to November 20th, 1915. It gives an account of the work of the fund under many headings, and includes a description of the admirably designed and administered Lady Hardinge Hospital at Broekenhurst. It is illustrated by photographs of various parts of the building, including a kitchen when the process of making chapattis was in progress. The fund works in close co-operation with the joint committee of the Order of St. John of Jerusalem and the British Red Cross Society, and in addition to all its other work the fund has taken up systematically the supply of comforts, and such clothing as is required, to the Indian prisoners of war in Germany. Most of the men are interned at Zossen, and in an appendix a report by an official of the embassy of the United States in Berlin is reproduced; it is of a favourable character.

CANADA.

In view of the demand for medical officers for service overseas, the military authorities have requested the A.D.M.S. of each division in the Dominion to take a census of all qualified practitioners who are available for service.

The fourth year medical students at the Universities of McGill and Manitoba have requested that instruction be given throughout the summer months of this year so that they may be given their degrees in the autumn and be able to enlist at once, they, on their part, agreeing upon graduation to offer themselves for service overseas. The faculties of medicine, however, do not consider that it would be in the interests of the students themselves to crowd the work of the final year into a short six months, and it is doubtful whether the licensing boards would agree to consider this an *annus medicus*.

MEDICAL OFFICERS WANTED.

32nd East Anglian Field Ambulance.

A medical officer is required for this ambulance. Imperial service obligation. Pay and allowances as in regular army, also unit and field kit allowance. Applications to the Officer Commanding, Hulton Park, Tring.

21st Highland Mounted Brigade Field Ambulance.

Three medical officers are required for this ambulance. Full particulars to be obtained from Captain Mowat, Officer Commanding, 2, Mount Street, Diss, Norfolk.

Scotland.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The Central Midwives Board for Scotland has been provisionally constituted as follows: Lady Balfour of Burleigh, appointed by the Lord President of the Council; Sir Archibald Buchan-Hepburn, Bt., by the Association of County Councils for Scotland; Sir Robert Kirk Inches, by the Convention of the Royal Burghs of Scotland; Lady Susan Gordon Gilmour, by the Scottish Branch of the Queen Victoria Jubilee Institute for Nurses; Dr. A. Campbell Munro, by the Society of Medical Officers of Health for Scotland; Professor J. Halliday Croom, M.D., F.R.S., by the University Courts of the Universities of Edinburgh and St. Andrews conjointly; Professor Murdoch Cameron, M.D., by the University Courts of the Universities of Glasgow and Aberdeen conjointly; Dr. J. Haig Ferguson, by the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow; and Dr. M. Dewar and Dr. J. Wishart Kerr, by the Scottish Committee of the British Medical Association.

THE EDINBURGH SCHOOL BOARD.

The report of the Board for 1914-15 gives some interesting information concerning the care of necessitous children. The nominal roll of the schools under the Board's care was 45,721, a small increase on the previous years, but the attendance showed a decline. The best attendance is in the autumn, the worst in midsummer. An account is given of the excellent arrangements for Special Children's Courts. These are held on Saturday mornings; cases for prosecution are notified by the police to the Board, the Board's officers attend the court and present the school record of the child. Equally effective are the arrangements for dealing with defaulting parents—a second fine is rarely necessary, and in a large number of cases a decision is held over on the parent giving a promise to keep the child in regular attendance in future. "The promise was invariably kept, and the case was withdrawn."

The Board has established, in a convenient central situation, a fully-equipped school clinic where children attend daily for treatment. The clinic has been working for two years. There are two dental chairs and apparatus for eye work. Four dentists, two oculists, and four nurses are employed. From September, 1914, to August, 1915, the following work was done:

	No. of Pupils.	Attendances.
Defective vision ...	944	967

Ringworm is treated by x-rays at the Royal Infirmary by arrangement—213 cases were dealt with and 188 cured; 686 pairs of spectacles were supplied and all were paid for by the parents, save 16, which were given free. The spectacles are contracted for at a low price. At the outset of the war there was a considerable increase in the need for feeding children, owing to the delay in the arrangement for the support of the dependants of those on military service; free dinners were given to all those whose fathers were on service from the outbreak of the war until Christmas when the arrangement was suspended. At present penny dinners are supplied to necessitous children, the average cost of the meal is 1.7 pence. The close working of the school authority and the police is a matter for remark. It is written: "The requirement as regards clothing and boots for necessitous children continues to be

met by the operations of the police-aided clothing scheme and other charitable agencies. During the session 2,043 children were supplied by the police with boots and clothing according to their needs. The following arrangements have been come to between the Board and the Committee of the police-aided scheme in dealing with applications for boots or clothing. The schedules which contain reports by the headmasters of the needs of the children are forwarded to the chief constable as they are received from the schools. Inquiries are then made by the police as to the character and circumstances of the parent, and the decision of the Committee with regard to each case is communicated to the Board." (The same arrangement, we are told, works very satisfactorily in Brighton.) A special point appears to be made of visiting the homes of neglected children and bringing into play the arrangements of the City Corporation for the cleansing of the bodies of the children and the furniture and fabric of the homes.

Ireland.

A MEETING of medical practitioners was held in the Adelphi Hotel, Waterford, to promote a testimonial to Dr. Joseph Power (Ardhunan, co. Tipperary), formerly President of the South-Eastern of Ireland Branch of the British Medical Association, in recognition of the very valuable services rendered by him to the medical profession throughout Ireland in connexion with the certification question under the Insurance Act. The meeting was of opinion that, owing to the financial and professional advantages conferred on the entire profession, the testimonial should command the spontaneous support of every one of its members. During the dispute between the profession and the Insurance Commission Dr. Power contributed to the daily press many able letters, which were the means of gaining much influential lay support. It was, however, as the author of the pamphlet *Facts about Irish Doctors and the Insurance Act*, which was circulated amongst Irish public bodies, that perhaps Dr. Power conferred the greatest service upon his colleagues. At the cost of much valuable time and at considerable personal expense, he organized, with local assistance, the profession in the south-east of Ireland, with the result that in this district the objectionable scheme for certification of sickness benefits, adopted by the Insurance Commissioners, met, perhaps, in all Ireland, its most formidable resistance. Subscriptions are limited to £1 ls. Dr. J. H. Jellett, 11, Beresford Place, Waterford, has been appointed treasurer, and will receive all subscriptions, which should be forwarded without delay, as the fund will be closed on March 17th next.

HOUSING PROBLEM IN DUBLIN.

Dr. P. C. Cowan, Inspector of the Local Government Board, recently delivered a lecture at the College of Science, Dublin, on the housing problem, in the course of which he said that it was estimated that about eight million men were employed in regular occupations in the United Kingdom, and that about one million of them had wages of less than 20s. a week. In Dublin, out of a total of 42,000 families, at least 14,600 were in a like condition, and 5,600 men earned not more than 15s. a week. Mr. Seebohm Rowntree had calculated that the minimum cost of the necessities for physical efficiency of families left no margin for rent in the wages of a man with a wife and three children, unless he earned more than 18s. 8d. a week, and controlled himself and his family with almost impossible austerity. Food was put down at 13s. 9d., coal at 1s. 10d., clothing at 2s. 3d., and sundries 10d.; total, 18s. 8d. The root difficulty of the housing question was the low wages of a large section of the working classes, and the calculation explained why the town population had to be recruited from the country, owing to the feeble physique of the young people brought up under the hard conditions of the poorer classes in towns. In 1911 the approximate numbers per 1,000 of families living in single rooms were: In England and Wales, taken as a whole, 32; in Ireland, 64; in Scotland, 125. The worst local figures in the three kingdoms were: In Finsbury, 277 per 1,000; in Dublin, 340 per 1,000; in Coatbridge (near Glasgow), 273 per 1,000. With a similar population, Scotland had more than twice the number of single-roomed houses than Ireland

In Irish cities and towns, and especially in Dublin and the adjacent townships, good examples of improved working-class houses provided by the sanitary authorities were to be found. The munificence of Lord Iveagh in respect of housing and the wisely-guided activities of the Dublin Artisans' Dwelling Company, a company founded mainly on philanthropic basis, were specially notable. In Cork 420 pleasing and suitable houses had been erected by the Cork Improved Dwellings Company, which, by careful management, was able to pay 5½ per cent. to its shareholders.

Dr. Lorcan Sherlock, in moving a vote of thanks, said that the Dublin Corporation did not always receive fair play from those who did not fully understand the many difficulties which had to be dealt with. The principal of these was the intense poverty of the working classes in Dublin and their absolute inability to pay an economic rent for the houses being built under the corporation schemes. If the workers of Dublin were to be properly housed, the responsibility fell on the employers to pay a wage sufficient to enable them to pay the rent for decent housing accommodation. Liverpool for £1,350,000 had only provided accommodation for about 2,000 families, whereas Dublin had provided for £400,000 accommodation for 1,200 families, and the annual charge on the rates of Dublin was only £14,000, as against £35,000 in Liverpool. He paid a tribute to the time and judgement the members of the Housing Committee were devoting to this question in Dublin, but the great difficulty they had to contend with was the want of sufficient money. Sir Lambert Ormsby, F.R.C.S.I., mentioned that the Association for Housing of the Very Poor, of which he was chairman, had for sixteen years paid a dividend of 2 per cent. on the houses rented at 1s. 6d. and 2s. a week to the very poor of the city. The Artisans' Dwelling Company had always paid 5 per cent. These two companies showed what could be done by a united and philanthropic effort.

England and Wales.

SOME time ago, while a number of nurses and patients of the Epileptic Colony at Warford, near Alderley Edge, were skating on a frozen pond, the ice gave way, and eight persons—nurses and patients—were drowned. Dr. McDougall, the medical superintendent of the colony, was quickly on the spot, and at the risk of his life, without divesting himself of his clothing, plunged into the water and saved three patients. His heroic conduct was highly spoken of by the coroner, and the Alderley Urban Council passed a special resolution. The Royal Humane Society has now notified its intention to award special testimonials to Dr. McDougall and other persons for their rescue work.

THE MANCHESTER AND DISTRICT RADIUM INSTITUTE.

The first annual meeting of the Manchester and District Radium Institute was marked by a sad incident. The meeting, which was held at the Manchester Royal Infirmary, was presided over by the Lord Mayor of Manchester at first, and later by Sir William Cobbett; as the Lord Mayor attempted to rise to move the adoption of the report it was noticed that he had great difficulty in speaking, and had to sit down again. He was seen to be seriously ill and was removed to a private ward of the infirmary. The attack, we regret to state, has since proved fatal.

The report stated that most of the work done during the year had been in the treatment of cancer, but it was hoped that the treatment of other diseases might soon be undertaken. The difficulties in the treatment of cancer were very numerous, and until a sure method was devised of checking the formation of secondary deposits it would be impossible to claim cures. The investigations of the Middlesex Hospital Cancer Research Laboratories on carcinoma and sarcoma in mice and rats had suggested the possibility of producing immunity by means of radium, but so far no methods had been devised to do this with certainty in human malignant disease. The practice of the London Radium Institute of only treating inoperable cases had been followed. All cases presenting themselves

were first seen by a surgeon, and only when he refused to operate was treatment by radium or x rays considered. The treatment of tumours by embedding tubes of radium had been carried on extensively, and in the case of large and deep-seated growths the results obtained by embedding were on the whole better than those obtained by the application of superficial plates. In a number of cases the primary growth had entirely disappeared, and much pain and suffering had thus been saved, but secondary growths, many of which in turn had been lessened in size, had prevented the attainment of the desired result. The number of patients registered during the year was 655, of whom 519 had received treatment, 93 had been found unsuitable, and several were still on the waiting list. The honorary secretary-treasurer, Sir William Milligan, in presenting the financial report, said that the last year began with a balance on deposit in the bank of about £9,000, but in July a further supply of radium was bought, costing £3,987, and the balance now in hand was £5,027. The director, Dr. Burrows, urged the establishment of a research laboratory, and in this he was supported by Sir E. Rutherford, who said that the radiologist and the physicist, though engaged in independent investigation, might be of the greatest assistance to one another. A committee was accordingly appointed to consider the question.

Correspondence.

EDUCATIONAL UNREST.

SIR,—I see you have reproduced in the pages of your JOURNAL [February 5th, p. 213] the question which just before the close of the session I addressed to the Prime Minister as to the appointment of a committee to inquire into the organization of our present educational system, with special reference to the changes to be introduced when the war is over. The Prime Minister's answer was not altogether satisfactory. Possibly he did not quite well realize all that my question suggested. He said that partial effect had already been given to the scheme foreshadowed last year, which was concerned with the development of scientific research, and that the President of the Board of Education would be prepared to consult all persons and bodies competent to advise. More than this, however, is needed if our educational system is to be brought into harmony with the conditions that will prevail after the war. The *Westminster Gazette* of Monday last devoted its leading article to "The Educational Unrest." That unrest undoubtedly exists. Numerous bodies have recently held meetings, and have referred in general terms to changes that are already overdue, the necessity of which the war has brought into striking prominence.

It may be that the committee which was appointed to advise as to further facilities for scientific research will offer many useful suggestions. But some more practical proposals are needed. It is to the application of science to the different problems that now confront us that our attention should be directed. No country has men who are more distinguished in the various branches of science than we possess. Where we seem to fail is in close association of science with the several activities, whether professional, commercial, or industrial, in which our people are engaged. To bring about this more intimate connexion of science with our daily work it is essential that those who direct our schools and colleges should be in full sympathy with scientific study, and should have had the experience necessary to realize its essential value.

There are many other problems connected with the organization of education that demand attention. Among them are questions affecting the relations of the central to the local education authorities, and questions affecting the duties of the citizen to the State and of the State to the citizen. In order that a beginning may be made in the consideration of these pressing matters, I have suggested the appointment of a committee, independent of any Government department, and I still hope that the Prime Minister may see his way to accept this suggestion.—I am, etc.,

Chilworth, Feb. 8th.

PHILIP MAGNUS.

DUTIES OF MEDICAL PRACTITIONERS IN CASES OF CRIMINAL ABORTION.

SIR.—Your summary of the position of the profession towards criminal abortion is open to serious criticism. You summarize it thus:

1. Any one who, knowing of the commission of a criminal offence, attempts to conceal his knowledge from the authorities may himself be guilty of the offence of misprision of felony—an offence, however, which is practically obsolete.

None of the published utterances on this matter—whether of judges, counsel, public prosecutor, the Council of the Association, or the Royal College of Physicians—makes any reference to attempts to conceal the offence of criminal abortion. All the references, without exception, are to abstention from giving information. There is all the difference in the world between active concealment and passive non-revelation. No one proposes that doctors should actively assist their patients to conceal offences. All that is contended for is that doctors should not be compelled to use, for the purpose of rendering their patients and others liable to prosecution for felony, information obtained by professional attendance on those patients. The difference is material. By actively assisting in concealment the doctor would be guilty of misprision of felony; it does not follow that he would incur the same guilt by mere passive abstention from action.

2. An ordinary citizen, not being a barrister or solicitor, is under a moral duty to inform the authorities when he has knowledge of the commission of a criminal offence.

This is incorrect. The obligation under which the ordinary citizen lies is not a moral, but a legal, obligation. The moral obligation is in many cases exactly the reverse. A priest is in this country, though not in France, under a legal obligation to reveal the knowledge, that may come to him in the confessional, of the commission of a crime; but, so far from being under any moral obligation to do so, he would by doing so not only violate his moral duty toward his penitent, but would also bring upon himself, on moral grounds, very serious disciplinary measures from his ecclesiastical superiors. Your pronouncement is in flat contradiction to that of the Royal College of Physicians, which states explicitly that the moral obligation of the medical practitioner is the reverse of what you say it is.

3. A medical man, however, is under no such moral duty where his knowledge is obtained in his professional capacity, so far, at any rate, as the offence of abortion is concerned.

This puts the exemption of the medical man much too low. It is a misnomer that amounts to *suppressio veri*. Not only is the medical man under no moral obligation to inform the authorities, but he is under a moral obligation not to inform them; and with this moral obligation his legal duty does not conflict. This is the kernel of the matter. This is the really important knowledge that emerges from the discussion. As to the moral obligation, few doctors, I think, have had much doubt; but many of us had an uneasy suspicion that the law laid upon us a duty in certain circumstances to violate that obligation. We now know that this suspicion was baseless; and the very important result of this discussion is that we have it now on unimpeachable authority that we can perform our duty as medical practitioners towards our patients without in the slightest degree encroaching upon our duty as citizens towards the State.—I am, etc.

Parkstone, Dorset, Feb. 7th.

CHAS. A. MERCIER.

* * * As our correspondent correctly points out, the offence of misprision of felony is a very different matter from the mere non-user of knowledge by neglecting to communicate it to the authorities. The fallacy in the above criticism lies, however, in the fact that Dr. Mercier has confused moral and legal duties. A legal duty is one to which the law will enforce obedience, whilst a moral duty is one which rests for its observance upon public censure only. Inasmuch, therefore, as the duty which lies upon ordinary citizens to inform the authorities of the commission of a criminal offence is one to which no legal

consequences attach, it is, as stated in our article, a moral and not a legal duty. This being so, there were in the case of medical practitioners, and also, as our correspondent points out, in the case of priests, two conflicting moral duties—the one owed to the patient and the other to the State; the result of the conflict being to establish the former at the expense of the latter in cases of abortion.

TEMPORARY DEAF-MUTISM AND BLINDNESS.

SIR.—Some cases of recovery from deaf-mutism during fits of laughter seem to point to vascular occlusion as a possible cause of the loss of function. From time immemorial it has been observed that shock or fright is accompanied by pallor, and the fact that the hairs sometimes stand on end is mentioned by Homer, who tells us that King Priam was so perturbed on a certain occasion that the hairs stood upright on his limbs:

Ὅρθαι δὲ τρίχες ἔσταν ἐνὶ γναμπτοῖσι μέλεσσιν.—

H., xxiv, 359.

This and Job iv, 15, being undoubtedly the earliest records of cutis anserina. The pallor which accompanies this condition of the skin, when not wholly due to splanchnic engorgement, being probably caused by paralysis of the vaso-dilator nerves; the unopposed and overaction of the vaso-constrictors, and possibly the natural contractility of the vascular tissue, resulting in partial or complete occlusion of the blood vessels, and consequently a diminution or complete cessation of the blood supply—a condition which in the case of the cerebral blood vessels seems to be an adequate explanation of those cases of hemiplegia simulating that caused by cerebral haemorrhage, though the cause may be very different from that of shock, the sudden recovery, however, from paralysis naturally precluding the supposition of cerebral haemorrhage or lesion. It is therefore reasonable to suppose in cases of deaf-mutism, that a similar and circumscribed occlusion of blood vessels to the centres for speech and hearing or their communications, and probably also to the centres for vision in cases of blindness, is responsible for some, at any rate, of such conditions originally brought on through peripheral shock and also by fright. During laughter the sudden increase of blood pressure to the head would, it seems likely, upon up the occluded blood vessels in the bloodless areas, and these flushed out with healthy blood, speech and hearing would return as suddenly as they disappeared, and the vascular nerve control stimulated to its normal activity prevent a return of occlusion, and permanent recovery ensue. Such recovery, however, could of course not take place if the occlusion became so complete or prolonged as to cause degeneration of tissue. The practical application of such theory would naturally be the stimulation of the flow of blood to the head by whatever means might be deemed advisable.—I am, etc.,

Liverpool, Jan. 25th.

WILLIAM BRAMWELL.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows:

	£ s. d.		£ s. d.
Mr. J. Lynn Thomas, C.B.	5 0 0	Collected by Liverpool	
Association of Medical		Chemists' Association	6 10 6
Women in India (per		Miss A. Singha	1 0 0
Dr. M. O'Brien)—		Australian Pharma-	
Dr. Mackenzie	1 0 0	ceutical Conference	
Major Godkin, I.M.S.	4 0 0	(per the Agent-General	
Mr. A. Chapman, pro-		for Queensland) (total,	
ceeds of dependants' prescriptions	0 10 2	1986)	127 0 0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Obituary.

JAMES STANLEY NEWTON BOYD, M.B., B.S.LOND.,
F.R.C.S.ENG.,

SENIOR SURGEON TO CHARING CROSS HOSPITAL.

MR. STANLEY BOYD, whose death was announced in the last number of the JOURNAL, was born at Shrewsbury, May 18th, 1856, his parents being Major James Boyd, 86th Regiment, and Emma, daughter of Henry Newton, a Burgess of Shrewsbury. He spent his boyhood at St. Heliers, Jersey, where his parents resided, and was educated at a private school there. He came to London in 1872 with an introduction to G. A. Parkes of Netley, by whose advice it is probable he was guided in taking up medicine as a profession.

He began his medical education at University College, London, in 1872, where he had a distinguished academic career. Pearce Gould, Pepper, Horsley, C. J. Bond, Stonham, and others who have become distinguished surgeons, were among his contemporaries. He was house-physician to Wilson Fox and house-surgeon to John Marshall, and was no doubt much influenced by the latter's teaching, especially in the application of scientific investigation to the practice of surgery. Boyd, like several of his contemporaries, owed much of his subsequent success to that disciple of Lister and Billroth, Marcus Beck, whose teaching of the science and the art of surgery was an outstanding feature of University College Hospital at that time.

He passed his examinations with honour to himself and his medical school, taking the Gold Medal in Anatomy at the first M.B. at the London University, and honours in his final M.B., B.S., in Medicine and Obstetrics in 1879. He became F.R.C.S. Eng. in 1881.

After taking his degree he became demonstrator of anatomy and of practical surgery, and surgical registrar, and the experience of this latter post had doubtless a great influence on his future career. By conscientious devotion to the duties of this office he laid the foundation of his thorough knowledge of pathology and of its important bearings in surgical practice. It made him a master of precise description of an operation and of the subsequent microscopic investigation, if necessary, to make the case record complete. In later life he would often refer to the value which such an appointment is to a young surgeon, if he took full advantage of the great opportunities it offered, and those who acted on this suggestion have never regretted it.

In 1882 he was appointed assistant surgeon to Charing Cross Hospital, and it was soon evident that he was an acquisition to the anatomical and surgical teaching of the hospital.

He became full surgeon in 1891, and since 1905 he had been senior surgeon to the hospital in succession to John H. Morgan, F.R.C.S., C.V.O.

He held most of the important posts at the hospital and school, such as lecturer on anatomy from 1888 to 1897, dean of the school from 1890 to 1895, pathologist 1886 to 1888, lecturer on surgery from 1896 to 1905, and on operative surgery from 1899 to 1901.

He was chosen as treasurer to the school in 1906, and held the post during a most critical period of the school's history till 1911.

At the time of his death he was surgeon to the Hospital for Consumption at Brompton, consulting surgeon to Paddington Green Hospital for Children, and to the New Hospital for Women, and to other hospitals in the suburbs. In addition to his hospital and private work he had been attending and operating daily at the 4th London General Hospital in his capacity of Lieutenant Colonel R.A.M.C. (T.F.). Boyd had been a member of the council of the Royal College of Surgeons for two years, and had been examiner in surgery at the Royal College of Surgeons and at Cambridge University.

Stanley Boyd has not written any treatise on surgery bearing his name, being too retiring and too modest to do so of his own initiative, but no one had a better pathological, clinical, or practical knowledge of surgery than he.

For these reasons he was chosen by others to write for them. In this way he was chosen to edit the twelfth edition of Druitt's *Vade Mecum* in 1887, and also the seventh edition of Green's *Pathology and Morbid Anatomy*,

at the request of his old friend, Dr. T. H. Green, his medical colleague at Charing Cross Hospital.

He also wrote articles in *Heath's Dictionary of Surgery* (Hospital Mortality and Hospitalism), in *Quain's Dictionary of Medicine* (Diseases of Mouth, Tongue, and Veins), in Treves's *System of Surgery* (Fractures), in the *Encyclopaedia Medica*, vol. i (Aneurysm), and other informing and lucid articles in current medical journals and at medical societies, amongst which may be named a paper read at the Medico-Chirurgical Society in 1893 on Artificial Anus Treated by Resection and Enterorrhaphy by Maunsell's Method, and others on Oophorectomy in Cancer of the Breast in 1897, and on Cancer of the Tongue, Mouth, and Fauces, with W. H. Unwin, in the *Practitioner* in 1903.

Some of Boyd's doctrines were not at first accepted, but in the light of later events show that he was a far-seeing man. In the early days of the Women's School of Medicine he was a lecturer on anatomy, and much of the success of that school was due to Stanley Boyd, who had the courage of his convictions and never failed to advocate the claims of women to be admitted to the examinations of the colleges and universities. Like all pioneers in this movement, it made him unpopular in some quarters. In another direction he was also a pioneer in believing that the only way to reorganize the University of London was to concentrate in a few centres for the teaching of the preliminary sciences, and much of the success which has now come to Charing Cross Hospital Medical School by its amalgamation for that purpose with King's College could have been effected years ago had the counsels of Stanley Boyd been adopted.

As another instance of his foresight it may be recalled that over twenty years ago he advocated in the public press that Charing Cross Hospital should be removed to a suburb south of the Thames. This led to much opposition, but his project has quite recently been adopted by a neighbouring hospital.

His lectures both in anatomy and surgery were as good and thorough as could be given. He was, moreover, a brilliant operator, bold but always careful, and experienced in every branch of surgery. He was keenly interested in the operative treatment of malignant disease, especially where the breast or mouth or fauces were involved, and his success in radical operations for these conditions was in some measure due to his sound anatomical knowledge.

The best tribute to his skill may perhaps be estimated by the number of his colleagues who owe him a deep debt of gratitude for his professional services either to themselves or members of their family.

Beneath a rather reserved and, to some people, a matter-of-fact manner, there lay a very sincere warm-hearted nature, ever ready to rejoice with his friends in their success and to show active and generous sympathy in distress. Boyd hated all sham and hypocrisy, and disliked slackers or slackness in work. This soon came to be appreciated by the students, and when acting as dean he applied these principles in the interest of the school.

He was a man of high principles and integrity, and willing to make great sacrifices for ideals. As chairman of the Medical Committee of the hospital and of the School Committee he showed much zeal and devotion in forwarding the interests, welfare, and progress of both, always bearing in mind that the benefits were mutually reciprocal.

Though not an athlete himself he was a great believer and supporter of athletics as a means of improving the moral and character of a school of the university.

The Charing Cross Medical School and Hospital have lost in Stanley Boyd an able teacher and a skilled surgeon as well as a successful administrator and organizer.

In 1889 he married Florence Nightingale Toms, M.D., of Chard, Somerset, who became surgeon to the New Hospital for Women, and subsequently held the post of lecturer on gynaecology at the Royal Free Hospital. At the time of her death in 1910 she was senior surgeon at the New Hospital and was acknowledged to be a skilful surgeon and clinician. Stanley Boyd had a true helpmate in his wife, and her death made a great difference in his life. His mother and one sister survive him.

DR. AMAND ROUTH writes:

Having entered University College Hospital as a student in 1873, the year following the entry of Stanley Boyd, and

with similar sequence having joined the staff of Charing Cross Hospital in 1883, I have had almost daily opportunity of appreciating his personal integrity and professional uprightness and skill during over forty years. The late Dr. Montague Murray, F. W. Mott, and the late C. J. Arkle soon joined us at Charing Cross Hospital, and we all worked there in perfect harmony.

Boyd laboured with disinterested zeal for the good of the hospital and school, and for the welfare of the students both during their hospital career and afterwards, and there was keen competition to become his house-surgeon.

His advice was sought and usually accepted by both colleagues and students, and his surgical opinion and help were similarly coveted in personal emergencies.

His friendship was deep and true, demonstrated mainly by acts of unselfishness, and his sympathy was genuine, but not on the surface, and was sometimes only truly realized when his help was being utilized in domestic or surgical crises. Indeed, he never failed one in emergency, and his counsel was so sound, so generous, and so clearly expressed that it always helped to clarify the outlook and lighten the difficulties of the situation.

As an instance of his unselfish impartiality I well remember how he acted when the obstetric physicians sought permission to perform all gynaecological operations upon their own cases. Most of the major operations had hitherto been in the hands of the surgeons, Boyd especially doing the bulk of the abdominal work. As soon as he realized that gynaecology was becoming a surgical speciality he helped to have all such surgical restrictions removed, although he knew, and so stated, that the change would inevitably lead to the majority of major gynaecological operations going to the special rather than to the general wards.

The unexpected death of Stanley Boyd has startled and distressed his old friends more than any professional loss since the death of Montague Murray in 1907. Their characters and lives were very similar, and their outlook on this world and the next was governed by a deep but unostentatious piety which controlled all their actions.

Such men as these exert an enormous influence upon the heart of a medical school, and their places will be difficult to adequately fill.

Dr. HARRINGTON SAINSBURY writes:

As one of Stanley Boyd's oldest friends, may I be allowed a little space in which to attempt, in brief outline, a record of the man himself as I knew him? Our friendship began over forty years ago at University College, London (he had come up to London from Jersey in 1872); it continued without a break and in close association until his death.

In the second chapter of the *Thoughts of the Emperor Marcus Aurelius* we find the ejaculation, "Whatever this is that I am, it is a little flesh and breath, and the ruling part": there it lies exactly, and in the case of Stanley Boyd it was the "ruling part" which ruled. Actually he was very vital, but constitutionally, even in student days, there were symptoms which made one anxious, and in the course of his career bodily disabilities occurred from time to time which might have taken the heart and the go out of any one less courageous. As it was, these did not deflect his course, even by a little; under the breath of the spirit his ship of life drove full sail for the port of duty; that was his aim and end from student days onward right through life, and the outcome of it all to the general eye was an abounding vitality.

Marcus Aurelius devotes the first chapter of his *Thoughts* to the several personalities which came into his life, and he ends up, "to the gods I am indebted for having good grandfathers, good parents, a good sister, good teachers, good associates, good kinsmen and friends, nearly everything good." Boyd's debt to the heavenly powers was a like one. I can go back to the charm of his Jersey home at St. Helier's, and recall happy memories of a visit there, when the circle was still complete, Major and Mrs. Boyd, a younger sister and brother forming that circle; and I can see there, in the simplicities and integrities and unaffected enjoyment of life which prevailed, the natural source of the qualities which characterized and adorned him. It was a military home, where duty

figured largely and cheerfully, and it has always seemed to me that, in consequence, Boyd retained much of the soldier's outlook all through his life; this impression has been deepened since the war began.

When Boyd came to London he saw a great deal of his uncle, Henry Newton, who had by then retired from a judgeship in the Indian Courts after a distinguished and strenuous career in that country. Mr. Newton, who regarded him almost as a son, had a great influence over him, and to that influence on the spiritual side of things much may be traced, in particular his sympathies with the Society of Friends; he often attended the Westminster Meeting.

A great friend of his at University College was William S. Tuke, the prognostics of whose life were brilliant, but the "dark economy of heaven" did not see fit to fulfil them here. Through him Boyd came to know Dr. Hack Tuke and his family, of long-established Quaker origin and traditions; here he found kindred sympathetic influences and friendships which endured.

It is not possible to name all those among his contemporaries at University College with whom he was associated, whom he influenced and by whom in turn he was influenced, but I would name in particular Victor Horsley (to whom in the earlier days he was much bound in a keen pursuit of elusive knowledge), C. J. Bond of Leicester, Dawson Williams, Arthur Quarry Silcock, Amand Routh, F. W. Mott, Montague Murray; the last three became colleagues of his at Charing Cross Hospital.

Amongst his teachers at University College Hospital one name stands out pre-eminently, that of Marcus Beck, a man who figured much more in his influence upon others, and in the affectionate remembrance which he implanted, than in the "alarums and excursions" which attend the presence of not a few upon the stage of life. Judged as a man who moved others, Marcus Beck was a great force; it is surprising how he is still loved and remembered.

I am not able to take up the tale of Boyd's professional associations and friendships after he joined Charing Cross Hospital, but I would like to give the names of two friends, John Abercrombie and James Galloway.

From about 1880 onwards began his connexion with the London School of Medicine for Women, to which, in the chivalrous way which was his wont, he gave without stint time and labour and his most serious endeavours; here, as always, recognizing for himself and others one standard only—namely, the highest. Many friendships had their origin in this school, and here he found, as his great reward, Florence Nightingale Toms, M.D., from a family well known and much respected in Chard, Somerset. They were married in 1889, and with his marriage began the happiest and fullest period of his life, for the two were united not only by the bonds of affection but by an exceptional community of tastes, interests, and ideals; they were husband and wife and at the same time true comrades. Mrs. Boyd died in 1910, to the sorrow of all who knew her, to his grief before all. Henceforward he continued to work with the same thoroughness but not with the same incentive, for joys could no longer be doubled, sorrows halved. He left special directions that his funeral should follow as far as possible in all details the funeral service of his wife; and if this was departed from by the introduction of a military element, it was done so after full consideration and in the belief that Mrs. Stanley Boyd would have welcomed the departure, proud of the work which he had given to his country in its hour of need, proud of her lieutenant-colonel.

What remains to be said? Stanley Boyd was a true friend, never so happy as in the doing of a kindness, and grudging no pains in the rendering of a service; it is consoling to think that there are those, and they are many, who will always miss him, for this is but a just tribute to his worth. If there are some who have misunderstood him—and who shall escape misunderstanding?—let them be assured that nothing petty, nothing ungenerous, lay behind, and that his intention ever pursued the ideals which claimed him.

His mother and sister, who have lived with him since 1910, may well be proud of him, and herein find their truest consolation.

CHARLES STONHAM, C.M.G., F.R.C.S.,

SENIOR SURGEON, WESTMINSTER HOSPITAL; COLONEL A.M.S.

MR. STONHAM, whose death was announced in the *BRITISH MEDICAL JOURNAL* of February 5th, was the third son of Mr T. G. Stonham of Maidstone, where he was born on March 27th, 1858. He was educated at King's School, Canterbury, and afterwards at University College, London, where he had a distinguished career as a student. He was gold medallist in surgery, in medicine, and in gynaecology, and held all the resident posts in the hospital. He won the Atchison Scholarship in 1881. He took the diploma of M.R.C.S. in the same year, became a Fellow in 1884, and was for some years senior demonstrator of anatomy and curator of the pathological museum at University College. In 1887 he was appointed assistant surgeon to Westminster Hospital, becoming full surgeon in 1895 and senior surgeon in 1897. He was lecturer on surgery and teacher of operative surgery at Westminster, and examiner in surgery at the London Society of Apothecaries and the Royal University, Ireland; he had been examiner in anatomy of the Conjoint Board in England.

Mr. Stonham was the author of a *Manual of Surgery* in three volumes and of various other works, including descriptive catalogues of specimens of medical pathology, surgical pathology (part ii), and gynaecology and obstetrics in the Museum of University College, and of morbid anatomy in that of Westminster Hospital. He contributed articles on gonorrhoea and other subjects to *Quain's Dictionary of Medicine*, and on brain abscess to the *Medical Annual* of 1888.

Mr. Stonham served in the South African war with the rank of major in the R.A.M.C. He was chief surgeon and officer in command of the Imperial Yeomanry Field Hospital, and wrote a report of the work of the hospital and of the bearer company attached to it. He was mentioned in despatches, and received the Queen's medal with four clasps. In 1901 he was made C.M.G. He was lieutenant-colonel in the R.A.M.C. (T.F.), commanding the London Mounted Brigade Field Ambulance, which he raised some years ago. On the outbreak of the present war he was mobilized with the ambulance, and in June, 1915, was seconded and made consulting surgeon to the forces in Egypt with the rank of full colonel. In that capacity he did excellent work. He continued to hold the appointment till he was prostrated by dengue and had to return home on sick leave. His illness proved fatal on January 31st.

Mr. Stonham was a sound surgeon, a bold and successful operator, an inspiring teacher, and a good organizer. As an examiner students sometimes complained of a slight brusqueness of manner, but in his decision as to the fate of candidates he was, we understand, more accustomed to temper justice with mercy than many judges more suave of speech. He was keenly interested in ornithology, a member of the British Ornithologists' Union, and the author of a beautifully illustrated work on *The Birds of the British Islands*.

He was a man of large experience and observation, and his knowledge of life, sense of humour, and raciness of speech made him an amusing and stimulating companion. In him the profession has lost a distinguished member, and his colleagues and many patients a valued friend. He leaves a widow and one daughter.

MR. WALTER G. SPENCER writes:

Charles Stonham was a man of great natural ability, who profited to the full by the teaching he received from the distinguished men then on the staff of University College Hospital. Marcus Beck was the great exemplar upon whom he modelled himself, whilst Berkeley Hill gave him the inclination to his particular department of practice. In addition, as obstetric assistant under Sir John Williams, he obtained a good introduction to abdominal surgery. For a short time he was a member of the surgical staff of the North-West London Hospital, also of the Cancer Hospital, and some years later he was for a time surgeon to the Poplar Hospital for Accidents.

Stonham's commanding spare figure, striking face, and the energy he threw into speech and movement always impressed students and colleagues. He was perfectly ambidextrous; his long thin hands were used most skilfully. He was a very rapid operator, beginning and ending quickly, yet proceeding with all due caution at critical

stages of the operation. He will be remembered at the Westminster Hospital for many brilliant successes, and for many acts of kindness to patients, students, and nurses. Whilst actively engaged as a hospital surgeon and in private practice he distinguished himself in other ways. In early life he was an enthusiastic mountaineer, was a member of the Alpine Club, and made some noteworthy climbs. He displayed perhaps the most original talent as an observer of birds. He filled his house with a beautiful and rare collection of birds and their eggs, and he published a large book on British birds, as notable for the guidance he gave to the artists in making the drawings as for the bird lore included in the text.

Stonham commenced his military service as surgeon in the Middlesex Yeomanry. With the outbreak of the South African war he organized and took out as surgeon-in-chief the Imperial Yeomanry Field Hospital. A remarkable incident occurred soon after landing. He, with his field ambulance arrived shortly after De Wet had attacked and captured the Derbyshire Militia. It fell to him, as senior officer present, to arrange matters with the Boer general and also to be the first to inform the British authorities of the mishap.

On his return, he actively continued this work by forming a mounted ambulance, and, in spite of lack of sympathy and financial support, his unit took part in manoeuvres, and when the present war broke out he was fully prepared, and could have taken it out to France with the first Expeditionary Force. But he had to undergo a severe trial to his patience; his trained men and horses were required to make up deficiencies elsewhere, and he had to spend a winter in East Anglia recruiting to replace what had been taken away.

At last he and his ambulance brigade were ordered out to Egypt. He was there soon appointed to inspect hospitals, and there are many testimonies to the good work he accomplished in the short period he was able to hold his post.

In recent winters he had suffered from emphysematous attacks, but a short holiday in the south had restored him. In Egypt this trouble recurred whilst he was weakened by dengue and dysentery. So he was obliged to go on sick leave to Cannes. There he failed to recover as in previous years; he reached home very weak, and died on January 31st. He was buried at Golders Green with full military honours. At the same time a service was held in the Westminster Hospital Chapel.

DR. WILLIAM BARKER BALE died at his residence in Stockport, Cheshire, on January 12th. He was a son of the late Dr. William Bale, J.P., for many years a medical officer to the Stockport Union and a member of the town council. The deceased, born in Stockport in June, 1866, was educated at Lancaster and studied medicine at the Owens College, Manchester, taking the diplomas of M.R.C.S. and L.R.C.P. in 1890. He was appointed medical officer for the Stockport Workhouse, an appointment he held for nearly twenty-five years; he was also medical officer for the cottage homes attached to the union, and public vaccinator. When Stepping Hill Hospital was built and, later on, when a sanatorium and new nurses' homes were erected, he was given the sole management of the medical and surgical arrangements. He gave evidence before the Royal Commission on the 'Poor Law'. Two years ago he rested from his official labours for some months; on resuming them, once more he worked hard, and had charge, since May, 1915, of the military patients. His professional reputation had gained for him a large private practice. In December he was forced to take six months' leave of absence, but he was too ill to quit his home, and sank rapidly. His widow, a son, and two daughters survive him. Every section of the community attended the funeral at Stockport Borough Hospital Cemetery in order to show their sincere sympathy and to pay their last tribute of respect to the deceased doctor, who was held in universal esteem and affection in Stockport and neighbourhood.

In the course of a lecture at the London School of Economics last week, Sir George Paish stated that it was the intention this year to maintain in the field, in place of an average of two millions last year, a force of four millions at a total cost of eighteen hundred or two thousand millions sterling.

Universities and Colleges.

LATIN IN THE MEDICAL CURRICULUM.

THE Court of Governors of the University of Sheffield on February 7th amended the statutes so as to provide that "students shall be entitled as from June 1st, 1915, until the Court of Governors of the Sheffield University shall otherwise determine, to enter the Faculty of Medicine of such University without being compelled to take Latin at the matriculation examination."

The University of Birmingham has also decided that Latin shall be an optional subject, students in future being permitted to offer a modern language or a science instead of Latin. The step was taken by the University of London in 1902.

With reference to the University of Manchester we have received the following letter:

The University, Manchester,
February 8th, 1916.

Sir,—In the report of the Committee of Management to the Conjoint Examining Board of the Royal Colleges, as well as in the report of the comitia of the Royal College of Physicians, it has been stated that Latin is no longer a compulsory subject in the entrance examination to the Faculty of Medicine in the University of Manchester.

I should be glad if you would allow me to correct this misunderstanding. The University of Manchester has not modified the matriculation requirements.

I am, etc.,

G. ELLIOT SMITH,
Dean of the Faculty of Medicine.

UNIVERSITY OF SHEFFIELD.

DR. ARTHUR J. HALL, F.R.C.P., Senior Physician, Sheffield Royal Hospital, has been appointed to the Professorship of Medicine, in succession to Dr. Duncan Burgess.

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

WAR SERVICE OF MEDICAL PRACTITIONERS.

THE Registrar informs us that the Royal Faculty of Physicians and Surgeons of Glasgow have been much gratified to observe the large number of those connected with the medical profession who are giving war service in various capacities. They desired to take some step which would at once mark their sense of the loyalty of these members of the medical profession and would encourage others to follow their example. With that twofold object, and after careful consideration as to the best method in which this could be attained, they have made an alteration in their Regulations for the Examination to the Fellowship of the Royal Faculty, which they consider will mark their sense of the value of war service, and will facilitate the entry of those who render adequate war service into the Fellowship without unduly lowering the standard of the qualification. The Fellowship of the Royal Faculty is an honour qualification, and is of deservedly high repute. It is open to registered medical practitioners of not less than two years' standing who pass an advanced examination in two of the principal subjects of medical science. The Royal Faculty, having in view the value of the loyal and patriotic services which those who are engaged in the war are giving to the State, and the value of the experience they are likely in this way to acquire, have resolved that in their case an examination in one of these subjects in place of two shall be accepted as sufficient, and that this privilege shall hold good in the case of candidates coming forward within five years after the termination of the war.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—Part I. *Medicine*: F. M. Allchin, G. F. V. Anson, T. A. P. Benbow, A. W. C. Bennett, K. H. Bhat, J. T. Bleasdel, C. E. Bond, C. V. Brainbridge, J. F. Buckle, G. E. Chissell, H. M. Church, P. S. Clarke, D. Crellin, R. G. Dani, A. R. K. Dina, G. G. Drummond, W. C. C. Easton, W. F. Eberli, M. Elias, C. A. L. Evans, G. I. Evans, S. W. Fisk, A. R. Fuller, C. H. Gilmour, C. C. Goodall, E. A. Green, H. E. Griffiths, A. B. Gunasekara, T. H. Gunewardene, H. M. Halliday, J. C. N. Harris, W. L. A. Harrison, B. Haskins, E. H. V. Hensley, E. L. Hopkins, W. A. Hotsen, H. Ingleby, G. G. Jack, T. H. Jackson, F. B. Jago, L. W. Jones, V. Kanemeff, T. L. Kan, I. Keess, C. E. Kindersley, R. P. Langford-Jones, M. E. A. Latif, H. Lewis, L. M. Lister, D. Loughlin, H. M. C. Macaulay, P. G. McEvedy, G. A. S. Madgwick, R. H. Maingot, L. A. Malik, P. S. Marshall, G. L. Maule, P. W. Mamsell, A. D. Millington, T. D. Morgan, A. G. Morris, B. Mountain, S. Muttiah, K. V. Muttukumaru, S. R. Nalliah, J. D. Oliver, M. Oliveira, A. J. Orenstein, P. E. D. Pank, E. W. Paul, G. Perkins, P. R. O'R. Phillips, B. R. Powell, D. S. Pracy, M. K. Robertson, G. C. Robinson, B. T. Rose, P. G. Russell, K. Sahib, E. Sakoschansky, W. H. Sava, J. E. Scamian, G. B. Sellwood, E. A. Shaw, C. Shaw-Crisp, N. A. Spcott, E. Stansfeld, W. Steadman, H. G. Störner, A. Sunderland, H. W. Taylor, L. D. Taylor, W. H. Thomas, J. A. Tippet, H. M. von Mengershausen, H. J. Wallace, J. Walton, H. A. Whyte-Venables, R. W. Willenberg, G. C. Williams, H. G. E. Williams, A. Wilson, T. Wilson, L. Zeitline.

Part II. *Surgery*: A. W. Adams, M. N. Andrews, G. F. V. Anson, K. D. Atteridge, A. J. Bado, K. L. Bates, T. A. P. Benbow, G. A. Beyers, K. H. Bhat, J. T. Bleasdel, E. S. Bowes, A. O. Courtice, P. A. Dargan, L. M. Davies, I. A. I. Davies, H. M. Drake, A. N. Drury, C. Y. Eccles, C. A. F. Evans, D. J. Evans, L. W. Evans, M. D. Evans, W. J. Evans, W. Farquharson, G. Fehrsen, E. A. Fiddian, M. R. V. Ford, C. Gould, H. E. Griffiths, C. G. W. Hahr, A. E. Hamlin, G. C. Hartley, A. N. Haworth, G. E. Heath, V. R. Hirsch, E. L. Hopkins, G. P. B. Huddy, H. Ingleby, V. C. James, A. R. Jennings, S. H. M. Johns, W. G. Johnston, J. G. Jones, L. W. Jones, C. E. Kindersley, E. A. Levisseur, H. Lewis, K. T. Limbery, G. A. S. Madgwick, R. H. Maingot, G. M. Miall-Smith, R. D. Moyle, K. V. Muttukumaru, H. M. Oddy, P. R. O'R. Phillips, A. C. Pickett, D. S. Pracy, R. Rau-Damodar, D. Rees, E. D. Richardson, M. K. Robertson, B. T. Rose, E. E. Samaraweera, J. T. Samuel, E. H. Schwab, C. P. Sells, G. B. Sellwood, E. Stansfeld, G. T. Symons, H. J. H. Symons, A. H. Taymour, W. H. Thomas, J. A. Tippet, B. S. Topham, H. M. von Mengershausen, P. E. Webb, H. M. Wherry, H. A. Whyte-Venables, H. G. E. Williams, A. Wilson, R. S. Woods, G. N. Younger.

Part III. *Midwifery*: G. C. Agarwala, A. M. Ahmad, J. Andrew, G. F. V. Anson, H. Archer, A. Arias, T. B. Bailey, T. A. P. Benbow, F. E. Bendix, H. J. Bensted, C. E. Bond, E. G. P. Bousfield, I. B. R. Brogden, W. W. K. Brown, H. S. Bryan, L. J. F. Bull, H. R. Buttery, H. H. Castle, L. A. Célestin, A. H. Clarke, P. S. Clarke, A. A. Cockayne, W. H. Coldwell, J. D. Constantine, G. F. Cooke, M. C. Cooper, L. Cunningham, R. C. Davenport, A. V. S. Davies, F. G. L. Dawson, M. A. B. Demerdash, A. B. Dummere, W. H. Dye, J. D. Dyson, A. W. F. Edmonds, H. E. Ekanayake, M. Elias, H. S. Evans, T. S. Evans, F. O. Fehrsen, E. A. Fiddian, M. R. V. Ford, M. E. Franklin, A. R. Fuller, D. H. A. Galbraith, G. T. Garraway, L. S. Gathergood, E. L. Glasier, H. E. Griffiths, E. Haigh, N. H. Harrison, B. Haskins, A. N. Haworth, J. A. Hill, G. Hoffmeister, W. O. Holst, W. A. Hotsen, J. B. Hume, H. Ingleby, E. E. Jenkins, T. Joekes, P. T. Jones, W. H. Jones, H. Lewis, N. M. Lewis, E. E. Lightwood, A. Lloyd, D. Loughlin, L. G. Lunnion, H. M. C. Macaulay, L. A. Malik, W. Marriott, P. S. Marshall, J. A. Martin, F. C. Mason, A. M. Matland, B. H. Mellon, G. M. Miall-Smith, H. W. L. Molesworth, E. C. de M. Morgan, R. Moser, E. W. Mottau, G. Moulson, D. M. Muir, J. J. Murphy, F. P. Nicholas, D. C. Norris, M. A. Omar, A. O'Reilly, J. A. P. Pereira, E. M. Pfeil, V. Philippe, E. S. Phillips, R. L. Portway, J. S. Ranson, C. Y. Roberts, M. K. Robertson, J. D. Rutherford, R. J. Scarr, G. B. Sellwood, R. G. Simpson, D. M. Smith E. Stansfeld, G. P. Totton, W. H. Thomas, R. O. Townend, H. M. von Mengershausen, O. Williams, A. G. P. Wills, A. Wilson, J. H. Wiseman, C. Young.

The Services.

EXCHANGE DESIRED.

CAPTAIN, R.A.M.C.(T.), home on special leave, due to return as M.O. to a regiment in France on March 1st, desires, owing to family reasons, to exchange with medical officer in hospital or administrative work in England. Address, No. 650, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Medical News.

THE King has appointed Mr. Harold Low, M.A., M.B., to be anaesthetist to His Majesty's household.

DR. AXELMER MAY, who was P.M.O. to the forces operating in Northern Rhodesia, is coming home to act as assistant to Colonel Sir Ahmroth Wright in France.

A QUARTERLY meeting of the Medico-Psychological Association will be held at 11, Chandos Street, W., on Thursday next at 2.45 p.m., when Dr. George M. Robertson, physician-superintendent of the Royal Edinburgh Asylum, Morningside, will read a paper on the employment of female nurses in the male wards of mental hospitals.

THE foundation stone of the Hospital for Tropical Diseases of the Calcutta School of Tropical Medicine will be laid by the Governor of Bengal, Lord Carmichael, on February 24th. The preliminary work of the building has already been begun. The whole of the money for the building has now been collected by Sir Leonard Rogers, Professor of Pathology in the University of Calcutta. The Calcutta School of Tropical Medicine was described and illustrated in the BRITISH MEDICAL JOURNAL of March 7th, 1914, pp. 562-63.

THE Home Secretary has appointed a committee to consider and report whether, having regard to the normal conditions of traffic in London, licences to drive motor cars, motor omnibuses, or tramway cars should be granted to men who suffer from some partial disablement by loss of a limb or other similar cause, and, if so, within what limitation. The chairman of the committee is the Assistant Commissioner of Police, and among the other members are Sir Frederic Eve, the secretary of the Soldiers' and Sailors' Help Society, the secretary of the Royal Automobile Club, a representative of the Local Government Board, and the managing director of the London General Omnibus Company.

A MEMORIAL tablet in memory of the late Dr. B. C. Antill Pockley, who was killed while on active service with the first Australian Military Expedition at Kaba Kaul, New Britain, on September 11th, 1914, was unveiled at the Sydney Hospital on December 22nd, 1915. The inscription on the tablet recalled the circumstances of Captain Pockley's death, as recorded in the *BRITISH MEDICAL JOURNAL* of January 2nd, 1915, p. 46, in the following words: "He died through giving to a wounded comrade the badge protecting his own life." Dr. Ralph Worrall, the senior gynaecologist to the hospital, by whom the ceremony was performed, paid a high tribute to Captain Pockley's attainments and character, and, in concluding his remarks, associated with the tribute thus paid to a noble young man, the names of three other medical men—Dr. Muir Smith, Dr. Eric Giblin and Dr. Arthur Verge—who had also given their lives to their country.

In his presidential address to the Society of Public Analysts, on February 2nd, Mr. A. Chaston Chaplin said that during practically the whole of the first year of the war skilled chemists were recruited for active military service; that was to say, men who, by their training and experience, were absolutely necessary in their civil occupations for the welfare of the country, whether in war or in peace, were accepted for ordinary military work. Many hundreds of highly trained chemists were to a great extent wasted by being put to military duties which could easily have been performed by men with no special training. Eventually the Board of Trade appreciated the facts of the situation, and in issuing its list of reserved occupations of cardinal importance for the maintenance of some other branches of trade and industry, mentioned analytical and consulting research chemists, who, it was directed, should not be accepted for immediate enlistment or called up for service with the colours without the consent of the Royal Society. Mr. Chaplin added that the president of the Royal Society has now appointed a committee to assist the society in connexion with matters relating to recruiting.

THE General Secretary of the Medical Defence Union informs us that Sir Henry Craik, M.P., has received a communication from the Financial Secretary to the Treasury with reference to the assessability of gratuities and bonuses granted to temporary lieutenants of the Royal Army Medical Corps. In general these sums are said to be given under the officer's contract for satisfactory service, and as such are liable to income tax. The remainder of the answer quotes the various sections bearing on the allowances due in certain cases, but as we have dealt with these sections in previous issues (as, for instance, in that of October 30th, 1915), it will suffice to say that Mr. Montagu points out that an officer in the R.A.M.C. will come under the relief provisions of Sections 25 (1) of the Finance (No. 2) Act, 1915, if his total income does not exceed £300, and that, under Section 13 (1) of the Finance Act, 1914 (Session 2) and Section 20 of the Finance Act, 1915, he will only bear tax in respect of the practice he has given up on the basis of the actual profits (if any) of the year, instead of on the average of the past three years.

It is satisfactory to find that the Brentford guardians have appointed a committee to consider a scheme for the supply of medicines to their sick poor. This reform, urged over and over again upon guardians by the Local Government Board, has been adopted in many parts of the country. In the metropolitan area the supply of drugs by the guardians has been compulsory for many years, and the provisions of the Metropolitan Dispensaries Order ought to have been extended to other parts of the country. It is a pity that the guardian who made the proposal at Brentford could not have done so without in a most reckless manner bringing charges against certain medical practitioners, whose names were not mentioned, but who might be supposed by the context to be some of the board's own medical officers. According to a report in the *Acton Gazette*, he said that he had seen in doctors' surgeries large bottles labelled A.D.T., which he explained to mean "any d—d thing." Now, Mr. Greville-Smith has either seen this label in the surgery of a Poor Law medical officer at Brentwood or he has not. If he has, he ought to have brought his allegation before the board, so that an inquiry could have been held which would either have established its truth or have shown that Mr. Greville-Smith's eyes had deceived him. As a matter of fact, we suspect that the latter alternative would have been proved to be correct. The story about A.D.T. was a chestnut early in the last century. We have never seen the label, and have never heard of any one except Mr. Greville-Smith who has.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Attilology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the *British Medical Association* is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

THE ANGULUS LUDOVICI.

J. C. (Edinburgh) writes: As a onetime demonstrator of anatomy I was interested in your reviewer's criticism of Professor Davis's *Applied Anatomy* (*BRITISH MEDICAL JOURNAL*, February 5th, 1916). While the angle is called after Louis, this last is the French form of the Frankish "Chlodewig," (Ludwig) and Ludovicus is the Latin for both forms. What is wanted in students' anatomy books is a line or two on the biography of the men whose names are embedded in anatomy, and it would be of great interest to the student to know that Sylvius was plain Jacques du Bois, and Vesalius, Wessels, and so on with others. Now that Latin is being done away with, as at Liverpool Medical School, we may expect considerably more confusion.

INCOMPATIBILITY.

DR. JOHN RITCHIE (Glasgow) writes, with reference to the note on this subject in the *JOURNAL* of February 5th (p. 224), as follows: If "M." will mix his ingredients as described below, and allow the mixture to stand aside for an hour or two, he will secure a fine clear solution. Dissolve the sod. salicyl. in part of the water. Dissolve the pot. bicarb. in part of the water. Dilute the tinct. ferri perchlor. with the remainder. Mix the sol. sod. salicyl. with the sol. pot. bicarb. Add the mixed solutions to the diluted tinct. ferri perchlor.

M.P.S. (Glasgow) states that he has dispensed the mixture in question many times, and has found it compatible if prepared in the following manner: To a solution of the sodium salicylate in half the aq. chlorof. placed in a large measure add gradually the tinct. ferri perchlor. mixed with the remainder of the chloroform water, stirring constantly till effervescence ceases. The result is a blood-red mixture, perfectly clear and stable.

MR. THOMAS STEPHENSON of Edinburgh calls attention to a note of a similar prescription given in his pamphlet *Incompatibility in Prescriptions*. He directs that the salicylate and the potash should each be dissolved in water; the former is put into the bottle and the ferric chloride added to it, then the potash solution, and the bottle is filled up with water. The result is, he says, a clear claret-coloured mixture without a trace of deposit or effervescence.

CHILBLAINS.

DR. J. FLYNN (Sydney, N.S.W.) writes with reference to recent inquiries as to the treatment of chilblains: I would recommend a trial of extract of suprarenal gland. It is true that one swallow does not make a summer, but the marked effect that followed the administration of gr. v thrice a day in a case under my personal observation that had for years tried calcium in various forms caused me to ask the question whether other factors than deficiency of lime in the blood do not enter into the causation of chilblains. It would be well to consider whether inadequacy on the part of the suprarenal system and its effect on the autonomous sympathetic does not play a part in this very troublesome malady.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	...	0	5 0
Each additional line	...	0	0 8
A whole column	...	3	10 0
A page	...	10	0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Observations ON GUNSHOT WOUNDS OF THE HEAD.

BY
COLONEL H. M. W. GRAY, C.B., A.M.S.(T.C.),
CONSULTING SURGEON, BRITISH EXPEDITIONARY FORCE.

In view of publications on this subject which have appeared in the medical press from time to time since the beginning of the war, it seems desirable to define the principles and practice followed, almost without exception, by the surgeons at work in the military hospitals in R—. These principles may be enunciated shortly as follows: We believe

That infected gunshot wounds of the skull and brain require more careful consideration and prompt attention than similar wounds of any other part;

That we can combat and prevent sepsis best by early and complete operations;

That we can prevent permanent disability in most cases by systematically removing foreign material or displaced bone from the surface or substance of the brain whenever these are accessible to legitimate surgery;

And further, that, by these precautions, the immediate results in the saving of life and more rapid restoration of function, when that is possible, are better than those obtained by more conservative procedures.

All experience has shown that the brain, sooner or later, resents the presence of any abnormality in its immediate coverings or in its substance. It is true that some small lesions of the skull or small foreign bodies in the brain have caused apparently no trouble to the patient, even after years have passed, but others, seemingly equally insignificant, have caused intolerable inconvenience, due to late effects on the brain, which removal of the exciting cause has not succeeded in relieving. This is more true, of course, in cases of actual lesion of the brain. It is rather sad to think of the number of men injured in the head during the South African war who afterwards became a burden to the State owing to derangements of the brain, and it must be remembered that the maiming effects of sepsis in that campaign were not apparent to anything like the same extent as in this one.

It has always been the aim of military surgeons to remove or ameliorate the physical defects produced by missiles. Removal of displaced bone, of foreign bodies, of blood clot, or of any substance which might interfere with rapid and smooth healing of the brain has been considered to be of the utmost importance no less than the combating of sepsis. We have discovered in this campaign no valid reason to depart from this line of thought. The immediate effects of sepsis, both in increasing the severity of the focal lesion and in causing diffuse inflammation of the brain and its coverings, have been impressed on our minds with dreadful force. The power of the brain to accommodate itself to extraordinary conditions, or, one might say, the power of one part of the brain to disregard even excessive injury of another part so that what is left "carries on" in a marvellous way, has also been very striking. But who can foretell that, later on, such cases are to be free, as never before, of sequelae which experience has shown to be so frequently inevitable?

Because of that experience and because no one can foresee how soon trouble will arise, it is surely right that we should do all in our power to prevent probable trouble. It is a matter of the greatest importance to establish the best method of preventing or eradicating sepsis, which is such a hindrance both to rapid healing and to successful attack on physical defects in the skull or in the brain. One is not justified in formulating rules which are based on results of operations performed at a period in the war when methods of dealing successfully and rapidly with infected wounds were not properly appreciated. It has been found that septic wounds of the scalp and skull are particularly easy to deal with when compared with others in that they can usually be completely excised, and the scalp sutured without danger. One might almost say that this procedure, in the hands of those who have mastered

the necessary technique, has robbed operation of its danger and has enabled surgeons to obtain results which compare favourably with those of equal magnitude in civil practice under ordinary aseptic conditions. These remarks do not apply, of course, to cases in which sepsis has already obtained a firm hold in the lacerated brain. The problems connected with such cases are much more difficult. Apparently success is then dependent chiefly on the provision of suitable drainage—a very easy thing to say!

Fragments of bone, when driven into the brain, are not usually septic at first, but tend to become infected fairly rapidly. Jagged pieces of shell almost invariably carry infection along with them. If large pieces lodge in the brain, results are very bad. Very small pieces, on the other hand, may not cause any trouble, but even they have been found sometimes surrounded by large abscesses.

While it is evident that the thorough removal of physical defects is desirable at as early a date as possible, there are objections to this, of which the most important is that patients do not travel well until at least a week or ten days after operation. During a period of active fighting they cannot be kept at the front, and therefore it would appear best that all except the most serious cases should be sent at once to the bases, so that they may arrive before sepsis has got a firm hold. At the front nothing should be done to the wound further than to remove any visible foreign material, to antisepticize the surrounding scalp, and to apply a suitable dressing. To judge from experience in Rouen, it would seem advisable that, if any operation has to be done at the front, it should be a complete one. Second operations appear to entail a greater risk, taken all over, in these cases than a complete primary one. The average case arrives at the clearing stations really in a less septic condition—although the wounds may be superficially badly soiled—than they do at a base, and results should on that account be more favourable.

The following remarks have, of course, no reference to very severe wounds caused by large pieces of shell, in which such an extensive part of skull and brain is blown away or where a rifle bullet causes such explosive intracranial effects that the patient does not survive more than a few hours.

We have seen many patients who on admission have been suffering from complete hemiplegia, and whose symptoms have cleared up in such a marvellous and rapid way after operation that only a negligible amount of paresis has persisted. On the other hand, we have seen cases who showed few or no symptoms, but who later developed serious complications and died rapidly, in spite of operation. It appears, therefore, that one ought not to pay too much attention to focal symptomatology as a guide to treatment, or even, in many cases, to prognosis.

We have seen many cases with extensive superficial injuries with little or no damage to the brain, and, on the other hand, many cases in which an insignificant looking wound of the scalp and skull was associated with most extensive injury to the brain. Whilst large, lacerated wounds are usually most septic and suppurative in the brain apt to be severe, yet we have seen cases of trivial and comparatively clean-cut wounds of the scalp to be associated with extensive fracture, and, after a few days, with such acute suppuration in the brain that only immediate operation saved the patient's life. The size or condition of the wound, therefore, is no indication of how the case will behave.

One is told that oedema of the brain, and shock or concussion accompanying a serious injury, are such that operation at an early stage is dangerous. Yet we hear of many patients who are brought into clearing stations in practically a moribund condition who, after immediate operation, in a few hours have so far recovered that they are able to speak intelligently and take food. Their injuries heal up perfectly well afterwards. It would thus appear that oedema and so-called shock are no bar to success. Indeed, it is likely that both oedema and shock will pass off more quickly when the physical defects are remedied—all the sooner the more thoroughly this is done. In wounds of other parts, oedema and tension due to interference with the circulation are relieved very rapidly by incision, removal of foreign material, and drainage. How much more must relief of the circulation be called for in a closed box like the skull! In serious cases delay does not, therefore, seem advisable.

In passing, one may be permitted to draw attention to the value of local anaesthesia for many of the cases. The solution need be injected only into the scalp tissues and pericranium. The skull, dura, and brain will thereafter be found to be insensitive. If adrenalin is mixed with the solution, bleeding from the scalp is reduced to a minimum.

After consideration of all these facts we are driven, in deciding upon a course of action, to pay more attention to the probable mechanical effects of the injury and the potentialities for infection rather than to worry much over the presence or absence of definite symptoms. The lesion is a traumatic one, the possibility of sepsis is great, and things should not be left to chance or until the development of some particular symptom. One must risk misinterpretation when one says such things. One does not wish in the slightest to depreciate the value of clinical investigation. Timely and effective operation does not interfere with that. There is no doubt that the lesions one has to deal with are chiefly mechanical and microbic, and must be treated by mechanical and antimicrobial remedies. If the mechanical disabilities are not relieved, the complicating infection has potentialities greater and more serious than in wounds of other parts.

Minor Operations.

Excision and suture of scalp wounds are said by some to be unnecessary. Such a judgement depends on the point of view. These excisions, while they do no harm when proper technique is employed, make the patient fit for duty again in a much shorter time; they establish a diagnosis of fracture in most cases with absolute certainty; there is no doubt that thereby they occasionally save life, they certainly prevent troublesome sequelae; they save time and trouble on the part of the attendants, and they save expense in dressings. (The original mastic and gauze dressing may be left until the wound is healed.) Captain J. E. H. Roberts, recording 207 cases of excision of scalp wounds, states that only in 8 did failure to obtain healing by first intention occur. One wound gave way completely. In the others, slight gaping, sloughing, or stitch suppuration occurred.

Reasons for Opening Apparently Unwounded Dura.

It has been shown repeatedly during this war that a pronounced depressed fracture of the inner table, although the dura may not be lacerated, is accompanied by a localized, usually more or less cone-shaped, bruising or pulping of the underlying brain. The base of the cone corresponds roughly to the area of comminution of the inner table. Owing to its elasticity the inner table must always be depressed considerably before it fractures, and the sudden localized blow on the brain causes the pulping. The amount of depression necessary to cause fracture varies in different parts of the skull. Such injury to the inner table and brain may exist without a trace of injury to the external table. In very rare cases intracerebral haemorrhage, sufficient to cause severe pressure symptoms, may occur.

The pulped area—a mixture of useless brain matter and blood—is an immediate source of irritation to the surrounding brain, because it is virtually a foreign body. In the process of healing a great part of it is replaced by "fibrous" tissue—a scar—which forms a remote source of irritation. The pulped mass is liable to become infected and to form a localized abscess or to lead to spreading encephalitis or meningitis, especially if the wound superficial to it is not rendered aseptic at an early date.

In cases where the force has been so great that the dura has also been ruptured, although pieces of bone have not penetrated, a definite pulped track, extending even for a couple of inches into the brain, may be found. This, when explored by the finger, resembles closely the track made in the brain by a foreign body. This shows the necessity for using x rays before operation to reveal whether or not a metallic foreign body is present. Operation should not, however, be unduly delayed in order to have this done. If the foreign body is beyond the reach of the finger, it is usually beyond the reach of legitimate surgery. By fitting together the fragments of the inner table one can often ascertain, with fair accuracy, whether any fragments of bone have been forced into the brain.

The mass of disintegrated brain matter and blood, whether on the surface or in the depth of the brain, interferes with the local circulation, and by this alone causes irritation similar to a solid foreign body. After its removal from either situation, pulsation usually returns at once.

Such lesions may be accompanied by persistent headache, focal epilepsy or paralysis, or even "optic neuritis." Their presence can usually be recognized, after the dura has been sufficiently exposed, in that the dura is somewhat discoloured, the brain does not pulsate freely, and the area feels doughy instead of elastic or springy.

When the dura is opened, the pulped material wells out like grease from a collapsible tube. Pulsation returns very quickly. If healthy brain matter is forced out, this indicates excessive intracranial pressure, and lumbar puncture or a decompression operation should be done at once. A small drainage tube, down to the hole in the dura, may be left in the wound for twenty-four hours. The dura is usually opened by a small crucial incision made by plunging the knife in for half an inch or so, at right angles to the surface of the brain. It is sometimes necessary to help out the pulped material by inserting a small forceps and carefully opening the blades.

Symptoms are usually relieved within a very short time. This relief is often most striking when the dura is opened at a second operation, the first (removal of depressed bone) having failed to relieve the symptoms.

In the hospitals the dura has been opened deliberately on more than fifty occasions, without fatality. The effect has been immediately and uniformly beneficial. In four cases in which the operators thought that the procedure was inadvisable, death occurred from abscess of the brain, spreading encephalitis or meningitis.

Operations where Wounds of the Blood Sinuses are Present.

These are done as a matter of course, because it is thought advisable to remove depressed fragments of bone—

(a) Which cause obstruction to the return of blood from any part of the brain, and

(b) Which may be, or may become, soiled, and cause septic thrombosis. It seems all the more desirable to remove such fragments if they actually penetrate the wounded sinus. The operation is, *per se*, not a dangerous one if proper technique is employed. For example, fourteen cases from the recent fighting were operated on. Only one died, and he had severe laceration of both cerebral hemispheres, besides the wound in the longitudinal sinus.

DRAINAGE OF THE BRAIN.

It is difficult to formulate any hard and fast rules about drainage of the brain. On the whole, it is probably best not to drain unless one is forced to do so. The presence in the brain of definite pus, of infected blood clot, of inaccessible, definitely infected foreign bodies, or of profuse oozing from a seriously lacerated area are the chief indications for it. If when operating some days after receipt of the wound it is found that pus is absent from a track which foreign bodies have made, it is usually unnecessary to drain. In some cases one may feel, however, that it is safer to insert a short drain for twenty-four hours or so. When aseptic foreign bodies, such as bone fragments, have been extracted, or when an area or track of pulped brain matter has been evacuated in which no penetration of foreign bodies has occurred, it is unnecessary to drain the cavity in the brain, but a $\frac{1}{4}$ in. rubber tube should always be inserted, from the angle of the wound, "down to but not into" the opening in the dura, for twenty-four hours. If pus, "smelly" blood-clot, clothing, hair, or a jagged large piece of metal is evacuated from the depth, a drain should always be inserted into the track, and it should be brought straight out through an unsutured part of the excised wound. Bacteriological examination of what is removed should always be made, even though actual pus is absent. If streptococci are found drainage should be maintained until the organisms disappear or become very few in number. If streptococci are absent it is fairly safe to be guided, as to time for removal of drains, by clinical signs alone.

It should be remembered that foreign bodies, especially flat pieces of bone, compress the brain in front of them; therefore, although they may be found at a depth of, say, $1\frac{1}{2}$ to 2 in., it is not necessary to push a drain in to that

depth. The distal end of the track will, after extraction of the foreign body, be found to have approached considerably nearer the surface of the brain. If one attempts in such a case to push a stiff drain in for a couple of inches, there is great likelihood that the lateral ventricle will be perforated by it. One should, immediately before inserting the drain, gently explore the track with the finger, and push the drain in only so far that it will not quite reach the extremity of the track.

As a rule, the drain should be shortened slightly every day or every second day unless pus continues to discharge from the depth in fair quantity. It should be borne in mind that a drain, especially a rigid one, acts like any other foreign body, and may stimulate pus formation, besides providing a channel for possible entrance of fresh infection. All drains should on this account be removed as early as possible.

Rigid drains are harmful to the brain, especially those with holes cut in them. The intracranial pressure may force normal brain through the holes or end of the tube. The constant friction of the pulsating brain against the hard foreign body must have a bad effect. The most satisfactory drain, on the whole, seems to be a piece of jaconet, batiste, or similar substance, folded concertina-wise, with small pieces of salt tablet embedded in its folds. As the salt dissolves it exerts a "hypertonic" effect on the surrounding inflamed brain. In certain cases, where the pus is particularly thick or profuse, or where streptococcal infection is present, it may be advisable to insert in addition one or two narrow tubes. Salt or "eusal" solution, of strength suitable to the infection, may be injected repeatedly, a few drops at a time, along the tube.

One must be careful, when inserting a drain, that damage is not done to the healthy brain lining the track. One must therefore note the direction of the track very carefully.

Points Constantly to be Kept in Mind.

1. There may be multiple injuries, therefore always have the whole scalp shaved.

2. The force causing the injury is usually very circumscribed, and its effects are therefore likely to be localized to the immediate neighbourhood of the part which has been struck. Injury by *contre-coup* has rarely to be considered.

3. Such localized forces, if they have been great enough to cause depressed fracture of the inner table, result, practically always, in definite injury to the brain, which asserts itself by immediate or remote cerebral disability. This may occur in pronounced form, although the dura is uninjured; in rare cases it has occurred even when no fracture of the external table has been seen. One need not refer to cases of immediate disability. Some interesting examples of remote disability have turned up already even in France. We have seen a good many cases now of men who were wounded early in the war, and whose wounds were considered so insignificant at the time that the patients were not even sent down the line. Later they were invalided on account of symptoms caused by the physical defect of the skull—to wit, depressed fracture of the inner table—which, of course, was treated without more delay.

4. Experience has shown that a properly conducted, complete operation, while it cannot undo the already existing damage to the skull or brain, facilitates repair, gives better immediate results, and tends to prevent troublesome sequelae more surely than an incomplete one.

5. Death is due, practically in all cases, to the effect of sepsis on the damaged brain. In any case sepsis will increase the amount of damage to the brain. The local injury, when thus complicated, is likely to "interfere with intellect or set up permanent paralysis." Apart from that, sepsis may cause necrosis of bone and thus prolong convalescence.

6. As our efforts will therefore be nullified in large measure unless sepsis is overcome, all operations must be preceded by removal of the sepsis from the area to be dealt with. Excision of the infected parts is the most rapid and certain way of doing this. It is only in very rare cases that this is not feasible. If it is not, the patient has probably very little chance of pulling through. The wound of the scalp and pericranium must be removed *en masse*. The fractured bone must be nibbled or trephined away. Proper technique is essential to success.

It must be pointed out that to excise the wound after turning down a flap is merely courting disaster. The brain cannot be dealt with so vigorously, but removal of pulped useless material and of foreign bodies will allow it to combat more successfully any infection. "Healthy brain substance possesses considerable power of limiting microbic invasion," but one cannot say that pulped brain or brain with foreign bodies embedded in it is healthy! As already indicated, in the majority of cases in which bone fragments alone are forced into the brain, the track leading down to them is not infected at first, but it rapidly becomes so.

7. Foreign bodies in the brain act deleteriously in four ways: (a) By their direct effect on the delicate pulsating brain tissue. (b) By favouring the development of sepsis. It is practically an everyday occurrence during a "rush" to find suppuration around pieces of bone lying at the end of a track in the brain. (c) By interfering, in rather an obscure way, with the circulation of the brain. A mass of pulped brain matter acts in the same way. It is very common to find that the brain, when exposed at operation, does not pulsate, or does so only to a slight extent, until the fragments of bone or disintegrated matter are removed from the depth, when it begins to pulsate freely. A normal circulation is essential to satisfactory recovery. (d) By causing, when they become encapsuled, a localized connective tissue mass which may act as deleteriously as a tumour. If recovery of function is possible, removal of foreign bodies will procure this more certainly, more rapidly, and probably more completely than is otherwise feasible—a great improvement is frequently noted within twenty-four hours. If carefully done, further damage to the brain is not appreciable. In only one case have I seen any immediate increase of paralysis follow—when an unusually large piece of bone had to be removed from a suppurating track. One will likely do less harm to the brain in removing a foreign body through an already existing track than by cutting a way through a mass of fibrous tissue, or, worse still, healthy brain, as has to be done when the operation is postponed till the scalp has again become intact.

8. It is highly desirable to try to prevent the formation of cicatricial tissue whether on or in the brain, even though in the latter case it may resemble neuroglia. Such scar tissue acts as an irritant chiefly by preventing normal movement of the brain, by interfering with the circulation, and, in many cases, by causing pain. The nature of the injury, the amount of sepsis, the presence or absence of foreign bodies, and the treatment employed have much to do with the amount formed. Unsuitable drains, especially when kept in for a long time, stimulate its formation. The trephine opening should be covered completely with healthy scalp. It is dangerous to replace any of the fragments of bone because they are likely to be infected. The scalp wound, after excision, can usually be accurately sutured over the opening—in some cases it may be necessary to perform a plastic operation, by sliding flaps. This is greatly preferable to merely covering the exposed brain by a flap of muscle, pericranium or aponeurosis. Such a flap, if exposed at the bottom of a wound, is apt to necrose. In any case, the amount of cicatricial tissue and of permanent adhesion is greater in a wound which heals by granulation than in one which heals by first intention. It is true that Nature has a marvellous capacity for remedying defects—even by making a new dura. The greater the amount of abnormality, however, with which she has to cope, the greater will be her difficulty in imitating the *status quo ante*. Therefore we should help her in every way possible. When this help is given efficiently, the wound responds by healing *per primam*. The surgeons who have kept statistics will support the statement that, in patients who recover, at least 90 per cent. of the wounds behave in this desirable way.

TREATMENT.

Objects.

The objects of our treatment can now be shortly summed up.

1. To prevent or remove infection, thereby preventing further destruction of tissue.
2. To establish diagnosis in some cases of doubt.
3. To remove all sources of irritation to the brain, if this can be done without causing further serious

damage to it. One cannot undo the initial surface wound or cerebral lesion, but one can try to procure a condition which will allow healing to occur more rapidly, more normally, and with less permanent impairment of function.

4. In any case to procure rapid healing of the superficial parts, provided that the brain is safe.

We may be charged with being too zealous in operating on head injuries. I cannot remember death occurring after any operation which was not one of urgency. We have regretted that we have not operated or operated sooner on some patients who have done badly. In all injuries we claim that operation furnishes an additional and usually accurate means of diagnosing the extent of the lesion. In minor injuries it has done no harm so far as can be ascertained, and it renders the patient fit to return to duty at a much earlier period than would otherwise be the case.

We believe that it is better to send a patient home with a healed scalp and healthy skull, inside which are the fewest possible potentialities for future brain trouble, than that he should go with the prospect of a later operation on an area which is obscured by many abnormalities. If it can be shown that this is done with as great safety as attends more conservative methods, our procedure is more than justified.

Sepsis and the exigencies of war will always make the proportion of failures a relatively high one. Unless these military exigencies will permit of "head" cases being retained near the front for operation and for a fairly long after-treatment, it is not likely that mortality and loss of function will be reduced to any great extent. It is difficult to see how better arrangements can be made, or, indeed, how any important improvement can be introduced in the methods for disposal of all classes of wounded which already exist.

The Routine of Treatment.

The following description of routine treatment carried out in hospitals varies only slightly from that given in a small set of leaflets issued in April, 1915.

On admission of the patient his scalp should be shaved, the wound thoroughly examined (the use of a probe is deprecated), two skiagrams taken in planes at right angles to each other, and an exhaustive neurological examination made. If the whole scalp is not shaved, other wounds, sometimes more important than the most noticeable one, may be overlooked. An aperient should be given and the administration of urotropine (15 to 20 grains every three or four hours) begun. If the brain is injured it is well, for future guidance, to make a bacteriological examination of the discharge. If brain matter is exposed or exuding from the wound, operation should be carried out as soon as possible. In most other cases, in absence of urgent symptoms, there need be no great haste, but in no case should operation be postponed for longer than a couple of days.

Excision of Wounds.

The majority of wounds of the scalp should be excised, and the bone beneath carefully examined. If no further interference is made, the wounds can be sutured, usually without drainage. It may be necessary sometimes to slide flaps in order to make up for defects in the scalp.

Depressed Fracture.

Every case in which depressed fracture of the skull is suspected should be explored without undue delay, whether sepsis is present or not. Delay—waiting for surface wounds to clean—too frequently leads to dangerous intracranial developments. If the edge of the wound is much inflamed and infiltrated, treatment with hypertonic saline applications usually makes it fit for excision in twenty-four to forty-eight hours. In most cases it is possible so to excise the wounds in both scalp and bone that an aseptic field of operation is left. If sepsis has already penetrated to the depth of the brain, the sooner operation is done the better. It is rarely necessary to turn down large flaps.

The injury comes under one of the following varieties:

1. Cases without Definite External Signs of Depressed Fracture.

Because fracture with displacement of the inner table or some other subcranial lesion may be present it is important that operation should be carried out.

(a) When the entrance and exit wounds are separated so far by a bridge of scalp that the line joining them traverses the bone, or if the patient has been stunned at the time of injury, the presumption is that the bone has been damaged. Such wounds and the track between them, as well as single gaping wounds of the scalp, should be excised *en masse*, including the pericranium. Injury, even mere bruising, of the periosteum usually means that the bone has suffered. If focal loss of function (even although evanescent), persistent headache or giddiness, or other more definite signs of cerebral compression are present, especially if optic neuritis coexists, trephining should be done, even in the absence of definite laceration of the periosteum.

(b) If fracture of the outer table without depression is found, or even if the bone is merely bruised, a small trephine opening should be made and the inner table examined. Depressed fracture of the inner table may exist without any cerebral symptoms, and only the very best skiagrams will show such a fracture.

Operation in such cases is practically without danger.

2. Fracture with Depression, but without Injury to the Dura Mater.

The fractured and depressed bone must be removed by means of properly devised bone gouge forceps if possible, otherwise a small bone disc must be trephined at one side of the fracture before using the forceps. It is better to work with a small forceps and nibble the bone away in tiny pieces than to use a large powerful forceps, which may cause extensive fissure fracture. It is not necessary in such cases to trim the edge of the opening in the bone. It seems likely that bone is thrown out more readily from an untrimmed margin, so that the opening may become greatly reduced in size. If the dura is apparently normal and the brain pulsates well, the operation can then be completed by suture of the scalp, with or without drainage. If, however, the dura is muddy-looking; if there is loss of pulsation and circumscribed loss of elasticity, especially if focal symptoms have been present after the wound was received, the dura should be opened. This is usually best done by a small crucial incision, made by stabbing a scalpel in at right angles to the dura. Disintegrated brain and blood clot are squeezed out by the *vis a tergo*. If the pulped material does not come out quite readily, it may be helped out by inserting a small artery forceps and opening the blades so as to dilate the hole in the dura. Only the useless matter will exude unless the intracranial pressure is high, in which case lumbar puncture, or possibly even a large decompression operation, is indicated.

3. Injury of Dura without Foreign Body or Sepsis.

Fracture with injury to dura mater, when no foreign body is present, and the wound in the brain probably aseptic. After excision, *en masse* as before, the scalp wound may be enlarged in any desired direction. It is very rarely necessary to turn down a flap. The bone around the fracture is cleared. A "trephine" opening is rarely required. The spicules are removed and the skull cut away carefully with forceps to an extent varying with the injury to the dura. A clear margin (one-third of an inch) of uninjured dura should be exposed. Ragged edges of dura should be excised. If a "track" exists in the brain, this should be carefully explored, by the finger if possible, and any collection of pulped brain tissue allowed to escape. A piece of aponeurosis may be drawn across the opening in the dura, and the operation completed by suturing the scalp wound. A drain of folded jaconet or small rubber tubing should reach from the opening in the dura through one end of the wound. It should be removed after twenty-four hours. If sepsis asserts itself, the wound should be freely opened up at once.

4. Injury to the Dura complicated by a Foreign Body in the Brain and by Sepsis.

The position of the foreign body is previously localized by x rays. At the operation (as in para. 3), the track through the brain matter can usually be explored by the index finger. It may be necessary to enlarge the wound in the dura slightly. The foreign body having been located, a suitable flat or slightly curved scoop is passed along the finger under the foreign body, which is then pressed against the point of the finger, and all three are carefully

and gently withdrawn. The greatest delicacy of touch is required during this procedure. The finger, in a flexible manner, must follow the previously formed track, and must not break through uninjured brain substance. Any stiffness of the finger must be avoided. The use of a forceps is apt to increase the damage to the brain.

If the operation is done within a day or two of the reception of the wound a drain should be inserted along the track. If it is performed at a later stage and no sepsis is apparent to the eye, one need not insert a drain deeply unless considerable oozing has been caused by the extraction of the foreign body.

If definite sepsis is present drains should be inserted leading straight out through the wound. In the worst cases the scalp wound should not be sutured till all danger has passed.

The exploration for foreign bodies by the finger at the primary operation is justified by the following considerations: (1) A track through brain substance is already present; (2) only very rarely is further injury to the brain caused by the procedure; (3) the frequency with which an abscess develops, should the foreign body be left in the brain; (4) if the wounds are large, sepsis has almost certainly penetrated along with, or following, the foreign bodies, and, as has been said, the sooner they are dealt with the better.

As already indicated, foreign bodies imbedded in the brain, by their direct influence and by their interference with the cerebral circulation, may produce symptoms of focal irritation and of compression or increased intracranial tension. If their removal does not immediately relieve these, and especially if hernia cerebri is threatened, lumbar puncture should be resorted to. If this fails to relieve the intracranial tension, subtemporal decompression may give relief, but has on the whole proved an unsatisfactory operation under these septic conditions.

5. Fracture with Injury to one of the Blood Sinuses.

Operation in such cases may be difficult on account of the alarming haemorrhage which may occur during exposure of the sinus. It should not, therefore, be undertaken by an inexperienced operator. The size of the superficial wound of the scalp or skull gives no indication of the extent to which the sinus may be injured. The results of such operations have been very favourable. Three of the procedures recommended for control of such haemorrhage have practically been given up—namely, lateral application of suture or forceps, plugging with gauze, and ligature. Plugging and ligature especially must be avoided behind the entrance of the parietal lacunae or cerebral veins. It has been found that practically all cases which survive the immediate effects of the injury are amenable to treatment by the application, under light pressure, of a piece of aponeurosis cut from the edge of the scalp wound or from the fascia lata of the thigh. The procedure is known as the "postage stamp" operation.

After free exposure of the hole in the sinus, haemorrhage therefrom being controlled by light gauze pressure, the "stamp" should be cut and spread on the palmar surface of the point of the operator's gloved index finger or on a small swab covered with batiste or rubber tissue. The perforation is then blocked by a finger of the other hand. All blood clot is carefully wiped away, the controlling finger is removed and the "stamp" applied rapidly over the perforation. Fairly firm equable pressure is kept up for a few minutes, when the graft will have adhered to the wall of the sinus. A hole, measuring $\frac{1}{2}$ in. by $\frac{1}{2}$ in., has been closed successfully in this way, and, judging by the ease with which this was done, it should be possible to close even larger ones. The graft should always be covered by scalp at the end of the operation. In these cases it is practically always possible to suture the scalp wound completely, a small soft drain being inserted close to but not on to the graft, and withdrawn in a day or so.

Lumbar Puncture.

Lumbar puncture has frequently been found to give relief in cases of local circulatory disturbance after operation—evidenced, for example, by persistent headache, recurring focal muscular spasms, or slight hernia cerebri. The amount of cerebro-spinal fluid withdrawn varies with the pressure of the fluid. It is rarely necessary to remove

more than 25 c.cm. or thereby. Usually the withdrawal of a much less quantity suffices. The process may be repeated several times if thought advisable.

Certain cases of large fungus cerebri have been cured by this procedure. If fungus is present, however, while it is to be regarded as a symptom of increased intracranial tension, it must be remembered that this is frequently due to the presence of foreign bodies or abscess in the brain or to more diffuse encephalitis or meningitis, and suitable remedies must be used for these conditions. If meningitis is present or if the fungus is fairly recent, rapid removal of cerebro-spinal fluid may allow infection to spread. The wound should always be exposed for inspection when lumbar puncture is done, because this may cause the herniated brain to sink back to a considerable depth, and protective adhesions may be torn. If lumbar puncture fails to alleviate the condition, a contralateral decompression operation may be tried.

Spirit dressing is usually employed for such cases. Picric acid ($\frac{1}{2}$ to 1 per cent.) or some astringent preparation may, with benefit, be added when discharge is free.

In most cases of hernia cerebri it will be found that posture has a marked effect, the protrusion being lessened when the patient is propped up in the "Fowler position."

It is not advisable to make lumbar puncture in the early stages after a wound of the brain has been caused, unless the dura is intact, or until the exact local conditions have been revealed by operation.

Operation.

The operation necessary in the majority of head injuries arriving at the base is a comparatively simple one. If preceded by infiltration of the scalp with local anaesthetic and adrenalin, haemorrhage and shock are obviated to a very great extent, and the operation made even more simple. The dangerous haemorrhage which may occur from large flap incisions is entirely prevented by this infiltration of the incision area with adrenalin solution, and, if some local anaesthetic has been added, the amount of general anaesthetic required is negligible.

All serious cases should be kept at the base hospitals for three weeks after operation, and even longer if one is not quite satisfied with their condition.

RESULTS.

The records of 135 cases admitted to R— from the fighting in the end of September, 1915, and those otherwise available at the moment from three of the hospitals (257 cases) show a total of 392 cases trephined with 58 deaths—a mortality-rate of 14.8 per cent. Cases are included in this list in which the patient's condition was so bad that mere cleaning of the wound alone was possible. Whenever bone, even superficial fragments, is removed, the operation is classified as "trephining." None of the cases died in which the lacerated brain was found free from visible pus. Recovery occurred in most of the cases in which the track was definitely septic and in many in which quite extensive abscess had formed, but it was very rare in cases in which large fungus cerebri had developed.

If 12 "hopeless" cases, which died within forty-eight hours of admission, are excluded from the September, 1915, series, the mortality-rate is only 9 per cent.

REFERENCE.

1 Treatment of Gunshot Wounds by Excision and Primary Suture. BRITISH MEDICAL JOURNAL, August 28th, 1915, p. 317.

The American National Association for the Study and Prevention of Tuberculosis reports (we learn from the *Journal of the American Medical Association*) that during 1915 more than £4,500,000 was spent in fighting tuberculosis. This is an increase of £3,500,000, as compared with the expenditure in the campaign against the disease ten years ago. From the care of tuberculous patients, which was at first its sole function, the work of the association has grown until last year more than £200,000 was spent on organization and education; an equal amount in examining, advising, and treating patients; more than £70,000 in teaching and treating tuberculous children, and nearly £150,000 in the care of tuberculous lunatics and criminals. The bulk of the money spent in the campaign was expended on sanatoriums and hospitals. These, numbering nearly 600, cost £3,850,000.

TREATMENT OF MAXILLARY FRACTURES.*

BY

V. H. KAZANJIAN, D.M.D.,

DEMONSTRATOR IN PROSTHETIC DENTISTRY, HARVARD UNIVERSITY
(HARVARD SURGICAL UNIT, FRANCE).

The subject of maxillary fractures is large, but that part of it which interests military surgeons is the immediate and effective treatment of cases that come to military hospitals as a result of gunshot wounds. The number of injuries of the head and face is by no means a negligible quantity, and their efficient treatment is somewhat out of

FIG. 1.

Ligation of Teeth with Brass Ligatures.—The wires are passed and twisted around the necks of different teeth, and then the upper and lower teeth fastened together. Bicuspids and molars are wired singly, but incisors and cuspids should be fastened together in pairs, as in the diagram, then attached to the corresponding teeth of the opposite jaw. This method is especially useful for simple fractures, or fractures with very little displacement, involving the mandible only. It is not applicable in cases with extensive wounds, which require more adequate drainage of the mouth than this treatment affords.

ported and controlled by muscles of mastication which have very great contractile power. It is exposed and very irregular in shape. Fracture of this bone, therefore, is very often associated with considerable displacement of the parts.

2. Fractures of the jaws are almost always compound, and, as the mouth is an ideal nidus for bacterial infection and subsequent complications, much is added to the difficulty of treatment.

3. Being the most mobile and exercised bone of the body, the parts of a broken mandible are very difficult to hold together.

FIG. 2.

Barton Bandage.—This form of bandage affords a simple and effective method for reducing downward and forward displacement of the mandible, and holding the two jaws in close proximity. The turn passing under the chin is applied in the direction in which the force is required.

There can be no mistake in diagnosis, but it is necessary to ascertain the number of fragments, the directions of the fractures, the amount of lost tissue, and the location of

the sphere of the general surgeon. It is true that these cases are rarely fatal, yet any failure to treat them efficiently may be followed by serious deformities of the face and inefficient masticatory power, with its resultant lowering of the resistance of the patient. On the other hand, immediate treatment will give very satisfactory results and facilitate such future work as plastic operations intended to restore the functions and cosmetic appearance of the face and jaws.

Fractures of the maxillae, especially the mandible, follow the same general lines, and their treatment is guided by the same principles as fractures of other bones, but certain local conditions have to be taken into consideration:

1. The mandible is a very mobile bone, and is sup-

ported and controlled by muscles of mastication which have very great contractile power. It is exposed and very irregular in shape. Fracture of this bone, therefore, is very often associated with considerable displacement of the parts.

The cases of fracture of the jaw we are called upon to treat differ widely from those met with in civil practice. First, there is an external wound, varying in size from a small opening to a very extensive lacerated wound of the face or under the chin; and, secondly, the fractures are always comminuted and often multiple, involving the upper as well as the lower jaw. In more severe cases there is loss, varying in amount, of bony as well as soft tissue. Moreover, the injury is rarely confined solely to the jaws, generally involving, in addition, eyes, ears, nose or pharynx.

foreign bodies as well as fragments of the bones or misplaced teeth. The x rays will give very valuable assistance, and a radiograph of every extensive case should be taken.

Treatment.

I will not discuss the care and treatment of the external wound, as that is not essentially different from that of a wound in other parts of the body, but confine myself to the matter of adjustment and setting of the bony parts.

Our aim must be to create a comparative immobility of the parts, and to restore the functional activity of the jaws as far as possible. It has been an accepted practice in the past, and one somewhat in use at present, to connect the parts together with wire sutures or metal plates fastened to the bones. This method, while useful in exceptional cases, has some serious objections. It quite often interferes with the normal occlusion of the teeth, creating deformities, and, as the mouth cannot be kept sterile, infection spreads, causing additional complications.

The oral surgeon, however, follows a different method. All the fixation is accomplished by utilizing the remaining teeth or roots and the alveolar ridges, assisted by bandages and chin and head supports. Our knowledge of the normal occlusion of the teeth gives us an excellent guide. This should be emphasized and followed very faithfully, no matter how extensive the fracture, or how much bony tissue is lost. Otherwise we may create very serious deformities that will upset the symmetry of the facial contour and the performance by the jaws and tongue of their normal function—the efficient mastication of food and proper articulation in speech.

It has been customary in the past to ligate the upper and lower teeth together with brass wires and support the jaw with bandages, a method which, while very simple and useful in many fractures as seen in civil life, I find of very little use, as the cases are complicated by external wounds.

If the fractures are anterior to the last lower teeth a simple splint of vulcanite or metal is made and cemented on, fitting over the teeth, allowing always room for drainage of the wounds of the mouth. This gives the patient the chance to use the jaws moderately. The same result is accomplished by using metal bands around the teeth and connecting these with heavy wires. If the fracture is at the angle of the mandible or along the ascending ramus, the lower jaw is attached to the upper either by rubber bands, silk ligatures, or wires, splints being made accordingly.

In cases which come under treatment late the question is more complicated. The external wounds in healing form scar-tissue, the displaced parts of the bones begin to

FIG. 3.

Modified Vulcanite Band and Wire Splints.—Either of these is applicable to fractures of the mandible, and are especially useful where there is loss of teeth and contiguous tissues. The heavy wire bar of the vulcanite splint affords a bridge over the lost tissues, and removes the objection to the continuous vulcanite type by giving adequate drainage to the mouth.

FIG. 4.

Intermaxillary Elastics.—Elastic bands drawing between hooks soldered to metal bands (which are soldered in pairs or triples to prevent elongation of the teeth in their sockets) are useful for gradual reduction of displacements of the mandible. Elastics can be applied by this method so that force may be exerted in any desired direction.

* Read at a meeting of the Military Medical Society mentioned in the BRITISH MEDICAL JOURNAL of December 18th, 1915, p. 905, and December 25th, p. 938.

form union, the muscles of mastication lose their contractile power, partly owing to want of use and partly through injury, and ankylosis of temporo-maxillary joints is very marked. In addition we have gross deformity of the face. In these circumstances the correction must be gradual. We have to fight against the cicatricial tissues, and that is always difficult. Mechanical appliances must necessarily be more or less complicated, and the degree of success is partly proportional to the ingenuity of the oral surgeon, as new appliances have to be devised to meet the demands.

Cases with extensive loss of soft and bony tissues are comparatively difficult to treat, and it is impossible to outline a class of appliances to meet them, as each has its own peculiarity and should be handled accordingly. We have, however, certain rules to guide us:

1. We must try to control the infected area

by free drainage and frequent irrigations, etc.

2. No attempt should be made to suture the soft parts with the idea of closing the gap until such time as permanent splints are adjusted and union of the bony fragments is well under way. This rule is practically universal with all the oral surgeons doing extensive work of this kind.

3. The appliance should be made with the intention of holding the dissociated parts in their normal positions, taking as a guide the normal occlusion of the teeth.

Fractures of the superior maxilla are easier to control than those of the mandible, as they are more or less firmly connected with the other cranial bones. If there is no displacement, simple bandaging is usually sufficient. More complicated cases are treated with splints made of either rubber or metal, assisted by straps passing over the top of the head.

Care of the Mouth.—The care of the mouth is a very important part of the treatment. It is very foul, owing to the inability of the patient to clean it properly. The wound, always opening into the mouth, gives a constant source of new infection, so that precautions should be taken by frequent packing, etc., to prevent the flow of saliva into the wound.

The following methods I have found very satisfactory:

1. Tincture of iodine is applied to the gums and teeth with a small piece of cotton.
2. Plodgets of cotton are saturated with hydrogen peroxide and rubbed over the teeth and all the mucous surfaces of the mouth as thoroughly as possible; this helps to remove particles of food, mucus, clots of blood, etc.
3. The mouth is irrigated with an antiseptic fluid.

The nurse should be instructed to repeat this treatment three or four times a day, except the use of iodine, which is applied only two or three times a week.

Complications.—Fractures of the maxillary bones alone are rarely fatal, but gunshot wounds are seldom limited to the jaws. The bullet may pass through or lodge itself in the head or neck, causing serious damage to the organs and tissues of the immediate neighbourhood. We must not overlook this fact, and the patient should be watched

very carefully in the first few days. It is highly important to examine the path of the bullet, and determine the amount of injury done as far as is possible.

The complication most dreaded is sudden haemorrhage. This is most common, of course, when the injury is in the immediate vicinity of good-sized blood vessels, particularly those of the neck. A very slight flow of blood, either from the external wounds or the mouth, should be carefully followed up. It may be the beginning of a serious haemorrhage.

FIG. 5.

Metal Band and Wire Splint for Maxilla.—A useful retaining appliance for fractures of the upper jaw, which has been used successfully in fractures involving the process carrying all the teeth of the maxilla, except the two last molars on one side.

FIG. 6.

A form of band and wire splint, useful in the reduction of multiple fractures of the mandible, where a one-piece splint is not practicable. It affords a method for the gradual reduction of extensive displacement of the broken parts, not found in continuous wire splints. (From casts.)

FIG. 7.

Kingsley Barr.—This appliance consists of a vulcanite plate holding at the sides square metal tubes, for the reception of squared heavy wires, which extend externally from the corners of the mouth along the cheeks. The splint is supported by a head harness connected to the bars. This splint gives an excellent anchorage from which to work to the mandible, in cases in which fractures extend to both jaws.

An extensive fracture of the superior maxilla may involve the cranial bones and lead to disorders of the higher nerve centres, a possibility which should be carefully considered.

Among the minor complications we may expect is ankylosis. In very many cases this is only temporary, due to the injury of the soft tissues and the non-use of the jaws. Yet if the injury is at the temporo-maxillary joint we may have serious results if the treatment is not in the right direction. To prevent adhesions the mobility of the joints should be encouraged.

The control of the inflammation, abscesses, and necrosis of the tissues is part of our general treatment.

Importance of Early Treatment.—The importance of early treatment of maxillary fractures cannot be overestimated. The appliances should be adjusted as soon as possible, as this assures the quickest and best result. I have noticed that on account of the unsightly appearance of the external wound there is a strong temptation to give attention to the wound, to the neglect of the setting of the bones. The wound should undoubtedly receive proper care, but the fundamental treatment must begin with the bony structure. If the patient has a fractured arm we do not wait several weeks or months before applying our splints or bandages. This rule holds equally true with fractured jaws.

War-time injuries to the jaws, with their attendant injuries to other parts and resulting constitutional disturbances, are best handled by the hearty co-operation of the general surgeon and the oral specialist, working together for the welfare of the patient by restoring to him as far as possible his normal facial appearance and the use of his jaws and teeth in the processes of mastication.

I desire to express my great indebtedness to my friend and colleague, Dr. F. H. Brigham, of the Harvard Surgical Unit, for the skill and care with which he has prepared the diagrams that illustrate this paper.

Brigade-Surgeon Lieutenant-Colonel Andrew Barry, I.M.S., of St. Andrews, Fife, left personal estate valued at £23,066.

THE report of the Surgeon-General of the United States Navy for the fiscal year 1915 shows that the death-rate was only 4.18 per 1,000 per annum. Three years ago there were 222 cases of typhoid fever with 15 deaths; the present report shows 13 cases with no death. This improvement is said to be due almost entirely to prophylactic inoculation. The rate for venereal diseases was higher than that for 1913, but lower than those for 1909-12. The rates for tuberculosis showed improvement.

DENTAL CASES AMONGST SOLDIERS.*

BY

SAMUEL A. HOPKINS, M.D., D.D.S.,

BOSTON, MASSACHUSETTS, U.S.A. (— GENERAL HOSPITAL, FRANCE).

Of those men who have received dental treatment at this hospital 16 per cent. were suffering from gastritis or other digestive disturbances, and nearly every one of these had been sent back from the front for this cause alone. In every instance a rapid improvement was shown after the diseased roots were extracted and the mouth and teeth cleaned, although in many instances no artificial teeth were supplied. We have never had so many grateful patients. Man after man came back to us and told us how much better he felt after even the limited treatment we were able to give. Where the man was in other respects capable of going back to the front we have supplied artificial teeth when it was necessary and possible. Our rule has been that when a man had two upper and two lower molars which occluded fairly well, and also useful incisors and cuspids, not to make plates. We are forced to omit many cases that might be greatly improved; but we have treated the aching tooth, and treated and filled many that we felt sure would suffer if not treated. We have noted a condition in many mouths which we rarely see at home. In many teeth which have enormous cavities the dentine has hardened and the pulp receded far beyond its normal position. These we refrain from touching when there is no history of pain and no sign of abscess formation, because the time of the average patient in these hospitals is not sufficient properly to treat and remove the pulp and fill the root canals; the patients' chances are seemingly better if we soak the hardened dentine in a saturated solution of silver nitrate and omit further treatment. A few cases of pyorrhoea alveolaris have come to us in which the mouth was so sore that the patient could not chew. These patients were sent to the hospital for no other reason, and to our great surprise yielded quickly to treatment. In more refined circles this so-called Riggs's disease is a much more difficult disease to cure, and differs in many respects from the cases we have seen in the army. All of the cases among the soldiers are characterized by enormous deposits of tartar around the necks of the teeth, which deposits, however, do not seem to push their way down upon the periodontal membrane surrounding the roots, so that there are few deep incurable pus pockets, and the characteristic odour of advanced Riggs's disease is rarely present. There is usually pus at the gum margins; but with the removal of these great concretions, and very few treatments with iodine, the mouth clears up wonderfully.

I have come to the conclusion that the cleansing of the teeth of most hospital patients would be a most profitable undertaking, for invariably the patient comes back in a day or two and tells us how much better his appetite is, and how much better his food tastes. Nearly all of these patients have great tartar deposits, usually quite easy to remove, and nearly all are swallowing with each meal an appreciable amount of pus. The youngest graduate, or even well-trained three-year students, could do this work under a competent superior, and I am sure it would be a great economy. Many of the nurses could be trained to do much of this work. In some of the States at home we are beginning to employ dental nurses for just such treatment. Of course it would be better still if the men could be started with a reasonably sound and clean set of teeth; but I realize that we are dealing with a great emergency, which must be met in the most efficient and at the same time most economical way.

Some of the cases of rheumatism are undoubtedly due to mouth conditions, while the progress of other cases toward improvement must be retarded by the absorption of these mouth toxins. At the present time at home, if a physician has a rheumatic patient, that patient is immediately sent to a dentist for an examination of his mouth, and, if necessary, x rays are used to discover if there are any pus pockets at the ends of the roots of teeth. Perhaps the pendulum is just now swinging too far in the direction of

the teeth as causal factors in this and other diseases; but it has been proven beyond doubt that blind abscesses and other diseased mouth conditions are responsible for a very large number of cases, and the removal of these foci of infection marks the beginning of the cure.

The same is true of some of the heart and kidney irregularities; but because of the brief stay of the patients at these neighbouring hospitals it is not possible in many cases to see the bearing of the mouth conditions upon these diseases. Here, too, repair work and mouth cleansing could be practised with great profit.

Another point which is of great economic value is the lowering of a man's resistance to disease because of the absorption of mouth toxins, and the derangement of his digestion because of his inability to chew. The unclean mouth harbours the germs of many diseases. The pneumococcus is present, so far as I know, in all mouths where Riggs's disease is present, and in many apparently healthy mouths also. The staphylococcus, streptococcus, streptothrix, and several forms of amoeba are found there in great numbers. In fact, the uncared-for human mouth is the prize bacterial garden of the world, and mouth-to-mouth infections are more common than we dare believe. Therefore—I say it with all seriousness—a supply of toothbrushes, and perhaps fine pumice, and a toothbrush drill at every training station, would be a most profitable investment of time and money. A number of us in the United States have started a dental hygiene movement; and because we know how impossible it is to teach an old dog tricks, we are confining ourselves to work on the children.

It is interesting to know the cost to a country of poor teeth, and these figures may give a rough idea. In the State of New York it costs 36 dols. a year for each child in the public schools; 40 per cent. of absences from school are caused by toothache; 67,000 children fail each year to pass their examinations, and cost the State an additional 36 dols. for an extra year's work; 40 per cent. of these fail because of wretched mouth conditions. A little simple arithmetic will show that the diseased teeth of her school children cost the State of New York nearly a million dollars a year; and I ask, simply as an economic problem, Does the care of the teeth pay?

DEFORMITIES OF THE JAWS RESULTING
FROM OPERATION OR INJURY.

BY

PERCIVAL P. COLE, M.B., Ch.B., F.R.C.S., L.D.S.Eng.,

HONORARY SURGEON, KING GEORGE HOSPITAL; ASSISTANT SURGEON,
THE CANCER HOSPITAL, AND SEAMEN'S HOSPITAL, GREENWICH;

AND

CHARLES HENRY BUBB, L.D.S.R.C.S.Eng.,

HONORARY DENTAL SURGEON, KING GEORGE HOSPITAL, LONDON.

ANALOGOUS types of deformity are occasioned whether the injury be accidental or, as in operations, deliberately planned. As, however, in the case of operation, the question of expediency and other modifying factors must necessarily be raised, it will be convenient to consider separately the deformities produced thereby. The method of treatment, however, depends on the type of deformity irrespective of the cause producing it. A survey of these deformities will give opportunity for the enunciation of certain fundamental principles of treatment and for the demonstration of methods adapted to giving them effect.

Traumatic deformities of the jaws fall naturally into two groups, according as they are, or are not, associated with loss of substance. Loss of substance may be the sole deformity, or be complicated by displacement of the remaining part or parts. In cases in which it is necessary only to replace a mass removed or lost, the problem is one of purely mechanical prosthesis. It is not our purpose to discuss at any length the technicalities of dental prosthesis, but rather to deal with those cases in which preliminary treatment is essential for success, or in which other than prosthetic apparatus is necessary.

*Read at a meeting of the Military Medical Society mentioned in the BRITISH MEDICAL JOURNAL of December 18th, 1915, p. 995, and December 25th, p. 938.

DEFORMITIES RESULTING FROM OPERATIONS.

I. Operations on the Upper Jaw: Resection of the Maxilla.

The deformity thus produced is typical of that resulting from loss of substance without displacement of the parts remaining. A satisfactory functional result can be obtained by the adaptation of a suitably constructed obturator, the objects to be attained thereby being threefold:

1. To separate the nasal from the oral cavity.
2. To restore the masticating surface.
3. To restore the facial contour.

Particularly in cases where the operator has been unable to preserve the orbital plate it will be found that the apparatus must of necessity be bulky. The usual method of securing the lightness essential for retention and comfort is to render hollow that portion of

FIG. 1.

FIG. 2.

the obturator which fills the gap on the affected side, and the material commonly used is vulcanite. We suggest an aluminium box, which can be cast separately, or a plate and box cast in one piece, together with the tags which serve to retain the vulcanite with which the teeth are afterwards attached. The apertures necessarily left are tapped and securely closed by aluminium pins with a corresponding thread.

The construction of the appliance, whether made of vulcanite or aluminium, presents no particular difficulties, but certain practical details deserve mention. It is sometimes stated that no attempt should be made to distend the cheek. This is certainly not the case. The cheek can be considerably built out. The cosmetic result is more perfect, no harm is done, and after the first few days no discomfort is felt.

The date of insertion is an important point. As a rule, it should be from three weeks to a month after operation. Broadly speaking, the more removed at operation the sooner should the obturator be fitted. More particularly is this the case where removal encroaches on the pterygoid region. This was well exemplified in a case operated on by Mr. Joseph Cuning. The patient was a boy from whom Mr. Cuning removed the maxilla for a nasopharyngeal angio-fibroma which had filled the antrum and nasal fossa, had found its way into the orbit, and encroached on the temporal and zygomatic fossae. Within a month a firm cicatrix had formed which prevented efficient opening of the jaws. It was found necessary to divide the cicatrix under an anaesthetic to enable a reliable model to be taken. The appearances before and after operation are illustrated in Figs. 1 and 2. The cheek was considerably distended; mastication and speech were perfectly restored. Wherever possible, the soft palate should be retained intact. If, as in another case operated on recently by one of us (P. P. C.), it is necessary to remove one half of the soft palate, the remaining half should be drawn across and fixed to the raw pharyngeal wall.

II. Operations Involving the Lower Jaw.

The operations to be considered under this heading include those undertaken to give readier access to growths of the tongue, floor of the mouth or tonsillar region, and those undertaken for growths invading or involving the jaw itself. In the former case the mandible will be merely divided; in the latter case the operation will include the resection of a portion or one half of the mandible. The

objects to be attained are the thorough removal of the growth, and if possible a satisfactory functional result. Generally speaking, the functional results after resection are far from good. This is due, we think, in many cases to the fact that the surgeon does not fully appreciate how valuable is the assistance that can be rendered him by the prosthetic dentist, and in other instances to the lack of that personal collaboration between surgeon and dentist which is essential for success.

It is freely admitted that no considerations as to function should militate against the thoroughness of an operation once undertaken, but no operation on the jaws should be performed until the question of function has been fully considered and a definite plan formulated for its preservation. The surgeon tabulates freedom from recurrence as a surgical success. The patient's gauge of success is his ability to enjoy life. The surgeon preens himself on his achievement; the patient may wish himself dead. The functional problems associated with operations and injuries of the mandible are essentially different from those concerned in corresponding lesions of the upper jaw. The fundamental principle, if mastication is to be efficiently preserved, is the maintenance of the mandible whole, part or parts, in its, or their, normal relationship to the maxillae. In other words, the normal "bite" must be accurately maintained.

(a) Simple Division of the Jaw.

The intrabuccal route for removal of the tongue, in many cases of cancer of that organ, is open to criticism on the ground of insufficient exposure. In growths involving the floor of the mouth and the deep postero-lateral regions of the tongue it is admittedly inadequate. Splitting of the jaw in or about the middle line is a valuable aid to free access in such cases, and were it not that in the most favourable circumstances convalescence is considerably retarded, it would, we think, be more frequently employed.

The lower jaw has notoriously a poor blood supply, and the insertion of wire to coapt the fragments, in what is necessarily a compound fracture constantly exposed to septic infection, leads to delayed and often imperfect union, and in many cases to necrosis. Apposition can be firmly and accurately maintained by means of an interdental splint. The essential factor is the presence of two or three moderately firm teeth on each side of the division site. It may be urged that the necessary teeth may not be present; that, if they are, the better prognosis in edentulous cases should determine their removal; and that the apparently flimsy interdental splint must soon become loosened and so fail in its purpose.

Fortunately the lower front teeth are usually the last to be lost and will, in the majority of cases, be found standing in patients already otherwise edentulous. Fortunately, too, their configuration and position render them peculiarly amenable to conservative methods, scaling, etc., and their preservation, if suitably treated for a week or ten days cannot conceivably add to the risk of the operation. That the splint is adequate to maintain apposition till union has occurred has been amply proved in two cases operated on at the beginning of the year (1915) by one of us (P. P. C.). In one case the growth involved the fore part of the floor of the mouth. A laryngotomy was performed, and the contents of the submaxillary triangle, together with the growth and half the tongue, were removed in one piece, aided by median division of the

FIG. 3.

mandible. Some secondary haemorrhage occurred in the mouth on the tenth day and a lateral fistula persisted for three weeks, but rapidly healed after two applications of x rays. Fig. 3 shows the splint *in situ* in this case. In another case—that of a soldier invalided home from France—the epithelioma involved the lateral margin of the tongue far back. A complete dissection of the anterior triangle, with the removal of the sterno-mastoid and jugular vein, was carried out. Ten days later laryngotomy

was performed, the jaw divided, and half the tongue removed.

In both cases interdental splints were fixed on the operating table, and the progress of the patients was precisely such as occurs after an intrabuccal operation. Both patients were fitted with artificial dentures, and were able to eat as well as though the jaw had not been touched.

Even moderately firm union cannot be expected in less than six weeks, and union will occur more quickly if a very fine saw be used to effect the division. This is due to the fact that the splint is fitted to the jaw before division, and, when fixed after operation, the fragments will be found separated by an interval exactly corresponding to the thickness of the saw used. It is necessary to obtain an absolutely dead fit, and to this end the splints were cast in aluminium. They were fixed to the teeth with a rapidly setting copper phosphate cement. No cement can be relied on to retain in position for such a length of time a badly-fitting splint presenting such a small surface and, for this reason, we emphasize the importance of casting in the preparation of this and other interdental splints.

(b) Resection of a Portion of the Mandible.

Invasion of the jaw is of grave significance, occurring, as it usually does, when the disease is far advanced. Many of these cases will be regarded as inoperable, both from the point of view of immediate risk and of ultimate prognosis. Resection certainly renders an operation more formidable and attended by greater risk, but from the nature of these cases great risks may justifiably be taken. In addition to the risk may be added the fear of the bad functional results obtained in these cases, and this latter consideration may be the deciding factor in deterring the surgeon from attempting a radical operation. The functional problem is here complicated by the loss of substance necessarily entailed. Difficulty arises only where removal implicates the whole thickness of the jaw, and these cases alone will be discussed. It is obvious that bony union cannot take place if the normal "bite" is to be maintained. It is, in other words, a question of union *versus* occlusion. It may be definitely stated that, in all cases attended by loss of substance, union must be unhesitatingly abandoned in favour of the preservation of the normal, "bite." The attainment of this object is much more difficult if the patient be edentulous, and it is particularly in this class of case that treatment is rendered more easy by a discriminating conservatism as regards the teeth. If the requisite teeth be present, an interdental splint can be adjusted, or a modified and reinforced Angle's appliance can be adapted to both upper and lower jaws. The bite in the latter case is controlled by lateral guiding shoes in the manner described by Aehner. In edentulous cases the principle of the Gunning splint must be adopted.

(c) Resection of One-half the Mandible.

The remaining half of the jaw, if subject to no control, is pulled backwards, downwards, and inwards, and the condition of the patient is truly pitiable.

We have been enabled, by the courtesy of Mr. W. E. Miles, to adapt a modified Gunning's splint to two such

FIG. 4.

FIG. 5.

cases under his care (Figs. 4 and 5). It will be noted that no attempt has been made to deal immediately with the gap left on the affected side, the sole object of the apparatus being to retain the sound side of the mandible in its proper relation to the upper jaw. It may be objected that the presence of such a splint militates against proper

cleansing of the mouth; that it will not be tolerated by the patient; and that the lower jaw will fall away from the splint and be insufficiently controlled. These objections were not sustained in practice.

Readier access was obtained to the operation site, which, as a glance at the splints will show, was left entirely uncovered. The ward sister was emphatic that the mouth was more easily kept clean with the splint than without it; the patient pleaded to have it replaced when it was removed as a test; and the light pressure of the bandages keeping the dressings in place was found amply sufficient to secure a snug contact of the lower jaw with the splint.

In both these cases the patients were almost edentulous. Should the necessary teeth be present, the modified Angle's apparatus, mentioned previously, could be utilized, but would probably not be so comfortable, at any rate in the early stages.

DEFORMITIES RESULTING FROM INJURIES.

These injuries have assumed considerable importance owing to their relative frequency during the period of the war, and to the functional disability that is apt to follow. This applies more particularly to injuries of the lower jaw, for, owing to its passivity in mastication and its fixity, functional incapacity, in injuries of the upper jaw, ensues far more rarely and can be readily remedied. The slightest inaccuracy in fractures of the lower jaw leads to a diminution in the efficiency of the masticatory power, and greater degrees of deformity result in more or less complete loss thereof.

In the case of a limb, shortening and deformity are not incompatible with the preservation of good function. In the case of the mandible, absolute accuracy of alignment is essential, and unless it is obtained smaller or greater loss of function must inevitably result. Such accuracy can only be obtained in the limbs by direct inspection and mechanical fixation of the fragments by plate or wire. In the case of the mandible, such a procedure as wiring is most emphatically to be condemned. Fortunately, the required accuracy can be obtained by other means. If each fragment can be adjusted and retained in its normal relationship to a fixed point—the upper jaw—it necessarily follows that the fragments are accurately adjusted as regards each other. Every fracture of the mandible should be treated in terms of the upper jaw. Special apparatus is necessary for each case, and, in view of the issues at stake, these cases should be immediately transferred to an institution where such apparatus can be made and where its application is understood.

(a) Fractures of the Mandible without Loss of Substance.

The fact that these patients usually possess an adequate number of teeth renders the task of treatment relatively easy. The treatment of a fractured mandible is not begun and ended with the application of a four-tailed bandage, nor should the policy of "good enough" be tolerated. There is no margin here for error, and no treatment is adequate which permits of its occurrence. The Hammond wire splint is easily made, but its use cannot be recommended where a choice can be exercised. To be efficient several firm teeth must be present on each side of the fracture, and in these circumstances the cast interdental splint is infinitely preferable and has a wider range of application. The drawings (Figs. 6 and 7), made from x-ray photographs, illustrate a fracture before treatment and the interdental splint in position. The patient is a soldier at present under our care. On y

FIG. 6.

two shallow molars are present on the smaller fragment, and the displacement was considerable. Reduction could not be effected without an anaesthetic, and here again we feel certain

that the accurate fit of the splint is the factor responsible for the maintenance of firm retention. The patient suffers little or no inconvenience, and is able to eat minced meat.

It will be noted, perhaps, that the bite has been raised. This has no bearing on the ultimate result, and could have been obviated by the use of Snow's face bow. Sketches of the splint used in this case are shown in Figs. 8 and 9.

The Gunning splint, or the modification of it known as Payne's cradle splint, is certainly efficient, but as it is necessary to abolish all movement at the temporomandibular joint,

its retention is necessarily attended by some degree of discomfort. Its use should be reserved for those cases not suitable for an interdental splint. The scope of the interdental splint can, we think, be considerably enlarged, and we are at present experimenting with some modifications to that end.

Fig. 7.

Fig. 8.

Fig. 9.

Rectification of slight degrees of mal-occlusion can be corrected by long and tedious orthodontic treatment, but such treatment is open to serious objections, and at best is a sorry means of dealing with what might easily have been prevented.

(b) Fractures with Loss of Substance.

Fractures with loss of substance are usually compound both outside and inside the mouth. The loss of bone may be immediate or result from consequent necrosis, which, in the case of the lower jaw, readily occurs. It is absolutely essential that these cases should be efficiently treated from the beginning. The main fragments must be retained in their correct position in relation to the upper jaw. Here, as in the case of partial resection, all considerations as to union must be abandoned in favour of the maintenance of this correct alignment. Teeth should be preserved wherever possible, for their presence renders more easy immediate and ultimate treatment. The most suitable apparatus will vary with, and be determined by, the needs of each case, and considerable scope for ingenuity is afforded. The methods finally to be adopted for the restoration of function will depend on the size and position of the gap, and on the number and disposition of the teeth remaining. These methods will be prosthetic alone or prosthetic and surgical combined. The purely surgical measures will consist of plastic operations for the reconstruction of the damaged soft parts and the introduction of bone grafts, to restore, where necessary, bony continuity in the basal portion of the jaw. It must be remembered, however, that owing to the configuration and articulation of the mandible, a lower denture can exercise, if teeth be present and favourably placed, the functions of an efficient splint and restore to the lower jaws that rigidity which has been necessarily lost or impaired. It will be found that in many of these cases a suitably adapted and strengthened lower denture will suffice to restore mastication completely.

Deformities that have been allowed to become established owing to tardy or inappropriate treatment have a cosmetic and functional aspect. The one is usually co-extensive with the other. Their prevention should be a

matter for earnest effort, as is their rectification a matter for urgent demand from the suffering patient. Ingenious and complicated apparatus has been devised for the rectification of these deformities. If, however, the deformity is not established, the necessity for such devices does not arise, and if deformity is established their ability to correct it must be considered as doubtful. Certain it is that in bad cases established deformity can only be rectified by surgical intervention. A case in point is now under our care. The patient had, since his wound six months ago, been under treatment both surgical and dental. Fragments of necrosed bone had been removed from time to time, and his jaw had gradually settled back on the affected side till his front teeth were biting far back into his hard palate. All but two teeth in the lower jaw had been extracted and a lower denture fitted in an endeavour to provide some kind of occlusion. His chin had receded almost to the level of the hyoid bone.

Skiagrams showed the lesion, situated in the right molar region, to be associated with considerable comminution. Consideration of his models and adjustment of them to the correct "bite" indicated that the jaw would have to be pulled forward to such an extent as to leave a gap of one to one and a half inches at the fracture site. Success seemed very doubtful, but his request was so urgent that we decided to make the attempt. Laryngotomy was performed, and by turning back a large flap extending well into the neck the site of the lesion was exposed. It was found that union, partly fibrous and partly bony, had occurred, necessitating the use of the chisel to break it down. Firm cicatricial bands were divided on the lingual aspect, and the main body of the jaw was eventually freed sufficiently to allow it to be brought forward to the desired extent. A previously prepared cast aluminium splint on the Gunning principle was immediately adjusted, a drainage tube inserted, and the wound sewn up. The patient's facial contour is completely restored, and a good functional result is confidently anticipated.

(c) Fractures followed by Trismus.

Fractures liable to this complication are those which occur in the region of the condyle. There may be no mal-occlusion, but the loss of function is more or less serious in proportion to the degree of trismus present. The knowledge that such complication may ensue will lead to the treatment of such fractures in the "open bite" position, thus obviating the crippling results of cicatricial contraction or callus formation.

ACCORDING to the *Journal of the American Medical Association*, a bill now before Congress proposes to appoint the surgeons-general of the army, navy, and public health service a board to select a site for a national leprosarium for the United States. The sum of £100,000 is provided for building and maintenance. The leprosarium is to be administered by the Surgeon-General of the Public Health Service, who will be authorized to admit any leper who presents himself or who may be apprehended or detained under the United States quarantine laws.

In a paper communicated by Sir Oliver Lodge, F.R.S., to the Royal Society on January 27th, Mr. F. Tinker related the results of a study of the microscopic structure of semi-permeable membranes and discussed the part played by surface forces in osmosis. Photomicrographs of the common precipitation membranes showed that they were composed of small precipitate particles packed closely together, and ranging from 0.1μ to 1.0μ in diameter. Each of these precipitate particles was itself an aggregate formed by the flocculation of smaller ultra-microscopic particles. Of the membranes examined copper ferrocyanide and Prussian blue had the smallest particles. The pores in a copper ferrocyanide membrane ranged from 8 to $60 \mu\mu$ in diameter. Their size was such that they block colloidal molecules mechanically, but not the ordinary crystalloidal molecules, even when highly hydrated. A very close connexion was found between the osmotic properties of a membrane and the extent to which the membrane capillaries were under the control of surface forces. It was thought probable that osmotic effects were the result of adsorption phenomena occurring at the surface of the membrane and in the capillaries, the membrane being relatively impermeable to solutes negatively adsorbed, but permeable to solutes positively adsorbed.

Hunterian Lecture

ON

ULCERS NEW AND OLD: JEJUNAL FOR DUODENAL ULCERS.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS,
FEBRUARY 4TH, 1916.

By SIR JOHN BLAND-SUTTON, F.R.C.S., LL.D.,
SURGEON TO THE MIDDLESEX HOSPITAL.

ABOUT fifty years ago the chronic duodenal ulcer was recognized as a clinical entity, and its treatment remained for many years in the province of the physician. Operations were performed for the relief of duodenal ulceration by Codivilla (1893), Dean (1894), and Dunn (1895). In the first decade of the present century W. J. Mayo, Mayo Robson, Moynihan, Paterson, and Sherren, and others

opened up a new field of surgical enterprise. We know that chronic ulcer of the duodenum is a common lesion; for some undiscovered reason, the ulcer, in the majority of instances, is situated within 2 cm. of the pylorus, and, as a rule, on the anterior wall of the duodenum, midway between its upper and lower borders. A chronic ulcer in this position is rarely

FIG. 1.—Dice-box shaped segment of the parts adjacent to the pylorus. The duodenal bulb contains a chronic ulcer. The parts were excised from a spinster, aged 55, who had been a dyspeptic for thirty years.

accompanied by physical signs, but it sets up symptoms so easily recognized that there is no reason for resorting to the ways of Zsigmondy in order to read them.

The duodenal ulcer often appears as a rounded depression in the mucous membrane with the muscular coat as its floor. In many, a layer of thickened peritoneum forms the base of the ulcer.

Occasionally it rests on the pancreas, the liver, or the gall bladder. An ulcer on the anterior wall of the duodenum may rest on the peritoneum covering the anterior abdominal wall (Fig. 1). A serpiginous ulcer may persist for years, creeping round the duodenum, scarring at one edge and deeply eroding at the other; the tissues forming its base are often diaphanous.

The peritoneal surface of the duodenal bulb in such a case is often white with scars (Fig. 2). The obstruction of the pylorus that frequently complicates ulcers is often due to oedema of the mucosa.

This condition also occurs with ulcers situated in the pyloric antrum (Figs. 3 and 4).

Some of the most troublesome ulcers in the pyloric region can neither be seen nor felt in the course of a gastro-jejunoscopy. A small duodenal ulcer can only be located

with certainty when it involves the peritoneum and produces a tell-tale scar. These small ulcers cause paroxysmal pain and digestive discomfort, the symptoms of "a vexatious duodenum and an agitated pylorus"; this neat epigram (unearthed by Moynihan) was framed nearly a hundred years ago by Sydney Smith, the brilliant writer and preacher, who studied medicine in Edinburgh, and later in life doctored his parishioners as a rural amusement.

The chronic ulcer of the duodenum is exceptional in another feature. In all regions of the body open to observation a chronic ulcer is liable to become cancerous, especially between the thirtieth and the fiftieth years of life; this is the age incidence of duodenal ulcer. We know that chronic ulcers

of the leg, lupus-scars, and gastric ulcers occasionally become cancerous, but this change in duodenal ulcers has never been proved, although they are some of the most chronic occurring in man. I have long sought among the living, the dead, and in museums for a

duodenal ulcer that has become cancerous; so far my search has been unavailing. Cancer arises in the duodenum, but not in the region that is the usual seat of ulceration. The frequency with which gastric ulcers become cancerous and the infrequency of cancerous change in duodenal ulcers are difficult of explanation. When cancer exists in the stomach, small fragments, detached by the churning movements, are transported with the chyme into the small intestine, but an implantation cancer in the intestine above the ileo-caecal valve is unknown. Shattock suggests that shed fragments of gastric cancer would not escape tryptic digestion. I agree with him.

JEJUNAL ULCER (PEPTIC ULCER).

The jejunal ulcer that follows gastro-jejunoscopy is often called a peptic ulcer, a term implying faith in the

FIG. 2.—A gastro-duodenal cylinder. There is a white scar on the anterior surface of the duodenal bulb. The interior of the bulb is shown in the upper figure; it contains an active ulcer; the transparent patches indicate the scars of old ulceration. Excised from a woman, aged 45.

FIG. 3.—Pyloric segment of the stomach with a callous ulcer. Excised from a dyspeptic actor, aged 48.

FIG. 4.—Pyloric orifice of the preceding specimen from the duodenal aspect; it shows oedema of the mucosa.

opinion that it is produced by the action of gastric juice. This ulcer, described by Braun in 1899, resembles the common ulcers of the stomach and duodenum and has sharp edges, often so sharp as to look as if it has been

through the new stoma. On opening the abdomen, the white scar of the original ulcer in the duodenum was visible; the area of the stomach involved in the gastro-jejunal junction adhered to the anterior abdominal wall,

FIG. 5.—The limb of jejunum concerned in an anterior gastro-jejunosomy. A peptic ulcer is seen in the efferent limb.

FIG. 7.—The limb of jejunum in the preceding figure opened from behind to show the almost complete effacement of the valvulae conniventes.

punched out. It is a dangerous ulcer, and occasionally perforates before protective adhesions have formed, and causes septic peritonitis that often has a fatal ending. Some peptic ulcers have thickened edges and run a chronic course.

A peptic (jejunal) ulcer causes pain in the epigastrium, aggravated by the ingestion of food; the symptoms often resemble so closely those associated with a duodenal ulcer as to lead patients to complain that the pain and discomfort, for which gastro-jejunosomy was performed, have returned. When a jejunal ulcer follows anterior gastro-jejunosomy there is often an area of tenderness, and sometimes a definite swelling, under the upper part of the left rectus muscle. This indicates that the ulcer involves the peritoneum on the anterior abdominal wall. I have had two opportunities of studying the changes in the jejunum that precede the formation of a jejunal ulcer, and I am able to exhibit one of the specimens.

In March, 1906, I performed anterior gastro-jejunosomy on a man, aged 44, for symptoms indicating the existence of a chronic duodenal ulcer. The operation relieved the man of his pain, and he remained in good health for nearly seven years; then the pain returned with great severity, and on the urgent representation of his medical attendant the patient was readmitted, December, 1914, into the Middlesex Hospital. He complained of pain following the ingestion of food, and there was a tender area and slight swelling under the upper part of the left rectus muscle near the costal margin. I had no doubt that the man had an ulcer in the immediate vicinity of the new stoma. With the help of x rays and an opaque meal, the material could be seen escaping, partly through the pylorus and partly

and, on detaching it, an irregular opening appeared in the efferent limb near the gastro-jejunal junction (Fig. 5). The segment of stomach and the cylinder of jejunum involved in the junction were cut away. The opening in the stomach was closed with silk sutures and the cut ends of the jejunum were joined, end to end. The man recovered easily and quickly. The changes that have taken place in the tissues of the jejunum adjacent to the new stoma are remarkable. Normally, the mucous membrane of the jejunum is thick and thrown into folds, the familiar valvulae conniventes (Fig. 6); but in this specimen the jejunal mucous membrane in the vicinity of the new stoma is thin; the valvulae are effaced (Fig. 7) and the muscular coat is thin and transparent. The hole occupies the efferent limb of the jejunum, just beyond the cicatrix marking the union of the stomach and gut.

A consideration of the structural alterations of the jejunum in the neighbourhood of the new stoma resulting from gastro-jejunosomy leads to some conjectures of high interest. There are no valvulae conniventes in the first 4 or 5 cm. of the duodenum, and its wall is thinner than in the remaining portion; it is often dilated, and forms the *bulbus duodeni*.

A remarkable transformation occurs in the jejunum when the escape of chyme from the stomach is transferred, in consequence of gastro-jejunosomy, directly into

the jejunum. The wall of the jejunum receiving the impact of chyme ejected through the new stoma becomes attenuated, the valvulae disappear, and the jejunal walls assume the peculiarities of the supra-ampullary segment of the duodenum. This change entails a liability to ulceration, so common in the duodenum. Thus surgery,

FIG. 6.—Portion of the jejunum laid open to show the valvulae conniventes.

by changing the environment of a segment of the jejunum, has evolved during this generation a new variety of ulcer. The time required to induce a segment of the jejunum to assume the characters of the supra-ampullary portion of the duodenum will probably be determined by subsequent observations.

It is the common opinion that the duodenal ulcer is caused by the impinging of acid chyme ejected through the pylorus on to the wall of the duodenum. The features surrounding the origin of a jejunal ulcer following gastro-jejunostomy seem to support the percussion theory, but so far the discussions on the mode of origin of gastric and duodenal ulcers pay but little regard to the influence of bacterial action. Most of us believe the stomach to be amicrobial as long as it can expel its contents, but observations on the fluid found in the abdominal cavity of patients with perforated gastric and duodenal ulcers prove that it often swarms with pathogenic micro-organisms, especially streptococci. These are introduced with food, especially milk, wittily described as "our most polluted article of diet."

It is noteworthy that a jejunal ulcer is rarely seen as a sequel to gastro-jejunostomy performed for the relief of cancer of the stomach. This may be explained on the ground that such patients rarely survive the operation long enough to permit a jejunal ulcer to form. It is established that a "peptic jejunal ulcer" may make its appearance six months after gastro-jejunostomy, or be delayed ten years.

Some surgeons attribute these secondary ulcers to faults of technique, or a method of suture different from that employed by the surgeon who criticizes the report; or the suture fails to completely control the bleeding from the cut edges of the gastric or the jejunal mucous membrane, and a haematoma forms.

There is very little evidence available for the incrimination of silk or linen thread; persistent sutures have rarely been found associated with secondary ulcers of the jejunum.

INDIRECT OPERATIONS ON THE VISCERA.

Few things are more remarkable in the history of surgery during the last quarter of the nineteenth century than the origin and development of operations on the viscera. This advance was the outcome of two discoveries—anaesthesia and antiseptics. Surgical boldness and dexterity have always been available, but after the discovery of anaesthesia surgical rashness knew no bounds, but sepsis curbed it. Since the detection of the cause of sepsis, and the discovery of means for preventing it, surgical enterprise has been safeguarded.

In dealing with the viscera surgeons advanced tentatively. The effects of the removal of a particular viscus, or even a portion of it, on the physical efficiency of the individual were unknown. The internal reproductive organs of women were regarded with almost fetish reverence. Instead of removing the uterus when occupied by fibroids, surgeons removed the ovaries with the hope of establishing an artificial menopause and inducing the fibroids to shrink. Gradually men realized that the ovaries are the dominant organs of sexual life. So with the prostate. Ignorant that a big prostate could be enucleated, surgeons, actuated by false ideas as to the effects which followed removal of the ovaries, excised the testicles, or divided the vasa deferentia, with the hope of causing the prostate to atrophy.

In the case of the intestinal tract surgeons were content to make an artificial anus in order to relieve obstruction caused by cancer of the colon or of the anus. In 1881 Bryant, in the course of making an artificial anus, stumbled on a cancerous constriction, and the operation ended as an impromptu colectomy. Since that event resection of the bowel and short-circuiting have reduced colostomy to the position of an operation of despair.

The class of operations just considered may be called indirect operations—they may relieve the patient but do not remove the disease. To this class gastro-jejunostomy for the relief of duodenal ulcer may be added.

It is admitted that the most favourable conditions for gastro-jejunostomy are a pylorus blocked by an inflammatory mass, and a stomach with muscular tissue sufficiently vigorous to propel the chyme through the new

stoma. A dilated stomach with an unobstructed pylorus is so unfavourable for gastro-jejunostomy that surgeons are at their wits' end to devise means for closing the pylorus, not only to compel the chyme to take the new route, but also to hinder an efflux of bile through it into the stomach. With an unobstructed pylorus gastro-jejunostomy cannot be relied on to cure a chronic duodenal ulcer, and as it exposes patients to the discomforts and risks of regurgitant vomiting and jejunal ulcers, I have gradually abandoned it as a routine method and prefer to excise the pylorus and the segment of duodenum containing the ulcer.

THE PYLORUS.

It is difficult to describe with certainty the functions of the pylorus. That it delays the efflux of chyme cannot be denied, but the rapidity with which a foreign body is discharged from the stomach into the intestine indicates that its controlling influence is by no means great. Smooth foreign bodies under 1 in. in diameter when swallowed are soon propelled through the pylorus.

In the course of operations the normal pylorus, when first exposed, is usually firmly contracted. A few minutes later it dilates, and, except for the vein that marks the boundary between the stomach and the duodenum, the pyloric sphincter is not easily seen. When the pylorus is excised it usually admits the index finger easily, but after the parts have been immersed in preservative fluids such as a mixture of alcohol and water or formalin solution, they contract and the orifice is quite small.

The examination of museum preparations gives a false idea of the size of the pylorus and also of its functions. I believe the pylorus is extremely sensitive. Like the buccal and anal sphincters, it gives no indication of its existence unless chapped or ulcerated. A chapped lip makes feeding painful; an ulcer near the pylorus makes digestion an ordeal; and an ulcer at the anus makes defaecation a daily terror.

One day I had stretched the anal sphincter of a man to relieve pain caused by an ulcer. Crossing the garden with my house-surgeon shortly afterwards I asked him which he considered more painful, a chapped lip or a fissured anus. He replied: "I don't know, for at the present moment I've got both."

Duodenal ulcers may be mere dimples in the mucous membrane, others (miscalled fissures) deeply eroded pits, or narrow ulcers extending through the mucosa to the muscular tissue. It is conceivable that when irritated by the passage of acid chyme a spasm is set up producing painful sensations.

The common form of dilated stomach—nicknamed splashy stomach—which was mainly responsible for bringing routine gastro-jejunostomy into disrepute, is worth some attention. I believe it is caused in some cases by spasmodic closure of the pylorus. Just as the small painful ulcer, or fissure, of the anus leads to irritative action of the anal sphincter, often ending in dilatation of the rectum and the pelvic colon, so repeated spasmodic contraction of the pyloric sphincter will produce dilatation of the stomach. Convinced of this correlation of events, I have excised the pylorus in such cases, with good consequences, but on the whole the conditions which give the best results to this mode of treatment are those in which there is a gross lesion at the pylorus.

Excision of the pylorus cannot be regarded as a serious physiological loss. Removal of the pyloric half of the stomach or of the whole stomach does not interfere with the nutrition of the body. I removed the stomach from a woman, aged 35, for cancer. She survived the operation three and a half years. A year after the operation she reported herself, and at that time was in excellent health. She complained that she could not eat so big a meal as her husband, but she made up the difference by "eating two meals to his one."

It is surmised that the pyloric sphincter hinders the premature escape of undigested food into the duodenum. It has also been suggested that spasmodic closure of the pylorus, originating reflexly from the ileum, is protective against overloading the small intestine with insufficiently digested food. This is amusing, for the idea presupposes the existence of mentality in bowels, a function usually regarded as the exclusive property of the cerebrum. Keith's observations on the islets of ganglionic nerve

tissue in the walls of the intestine suggest that thoughts may arise in a man's bowels as well as impulses suggesting ideas; indeed, Menenius Agrippa's famous fable of the Belly and the Members may have more foundation in fact than the retort of Balaam's ass.

THE TECHNIQUE OF PYLORECTOMY.

When the conditions are favourable, excision of the pylorus, to surgeons accustomed to intestinal operations, is a simple matter. Favourable conditions mean a narrow and elongated pyloric segment of the stomach and the absence of adhesions between the pylorus and the liver, or the pancreas, or the transverse colon. The disparity in thickness of the gastric and duodenal walls is embarrassing to the operator, but with practice the difficulty disappears. Extensive adhesions to the pancreas or to the liver are a bar to pylorotomy. The supra-ampullary segment of the duodenum is occasionally much shorter than usual and makes the suture of the cut end of the stomach to the duodenum a difficult proceeding. In the method I employ, the abdomen is opened by a median supra-umbilical incision. The parts in the neighbourhood of the pylorus are examined in order to verify the diagnosis. The condition of the stomach is investigated as well as that of the gall bladder. When the conditions are favourable for pylorotomy, the vessels are clamped and stripped from the pyloric region of the stomach, and the loose tissue between the supra-ampullary portion of the duodenum and the pancreas carefully detached, and all bleeding vessels secured with forceps. When the pylorus is sufficiently freed from its attachments a clamp is applied to the stomach, about 5 cm. from the pylorus; the duodenum is clamped beyond the situation of the ulcer, and the pylorus excised. This is the best stage of the operation in which to ligature the vessels as they are well exposed and easily accessible.

The cut edges of the duodenum and stomach are sutured in the manner of an end-to-end anastomosis. I always use thin sterilized silk for this purpose and for ligatures. It is tedious and unnecessary to describe in detail the methods available for sewing the cut end of the duodenum to the hole in the stomach. It is like stitching a sleeve in a shirt; the clever sempstress varies her methods according to the material and the size of the garment. So with the surgeon. In a case of extensive resection (Fig. 3) the line of suture in the stomach was 6 in. across. Not wishing to imperil the safety of such a long line of suturing by joining the duodenum to it, I implanted the cut margins of the duodenum into a fresh opening in the posterior wall of the stomach.

In spite of the careful ligature of vessels, there is usually some post-operative oozing from the tissues in the wound area, and it is wise to drain for forty-eight hours. The abdominal wound is closed with through-and-through sutures, the fascia being brought into apposition with intermediate sutures of thin silk.

The first patient I submitted to pylorotomy for duodenal ulcer was a woman, aged 35, at the Middlesex Hospital, in 1909. Gastro-jejunostomy had been performed three months previously, but the pain remained unrelieved. I excised the pylorus and the segment of the duodenum containing the ulcer. She made a quick and uneventful recovery. I have since lost sight of this patient. A few days later, when operating on a man for a duodenal ulcer, I found the conditions so favourable for pylorotomy that I excised the pylorus and the bulbous duodeni with the ulcer. Six years later I re-examined him with the help of *x* rays and an opaque meal and found the gastric efflux satisfactory.

I have excised the pylorus for chronic duodenal ulcer, according to the method just described, in twenty patients. In three of them I had previously performed gastro-jejunostomy. In one the symptoms returned three months after the gastro-jejunostomy, in another six years, and in a third two years. One patient, the sixteenth in the series, died. He was a man aged 38, transferred from Dr. Wynter's ward, with typical symptoms of chronic duodenal ulcer. At the operation an ulcer was found close to the pylorus on the anterior wall of a well-marked bulbous duodeni. I departed from my usual method and sewed the cut edges of the mucous membrane with catgut. The man made good progress until the fifth day, when his temperature rose to 103°. He died on the nineteenth day after the operation. The suture line had sloughed, in

two spots. I attributed the unfavourable result to the use of catgut.

SUMMARY.

Since the treatment of duodenal ulceration passed into the province of surgery it has become the routine practice to perform gastro-jejunostomy for its relief, in the hope that, by diverting the chyme through the new stoma into the jejunum, the ulcer will heal. If the pylorus is obstructed by the ulcer the results are usually good, because the chyme must flow through the new stoma, but when the pylorus is patent the chyme flows through it, and in some instances ignores the new route. This is not imagination, for the efflux can be watched with the help of an opaque meal and *x* rays. I believe it is better, whenever practicable, to excise the pylorus with the ulcerated portion of the duodenum and rejoin the stomach and duodenum on the principle of an end-to-end anastomosis. If this method could be made safe, gastro-jejunostomy for the relief of chronic duodenal ulcer with an unobstructed pylorus would soon be abandoned.

Experience proves that posterior gastro-jejunostomy with an obstructed pylorus is a beneficent operation, in spite of the risk the patient runs of getting a new ulcer for an old one. The new ulcer has been evolved during this generation by alterations in the environment of the jejunum brought about by surgery.

ANTENATAL CLINICS AND PREMATERNITY PRACTICE AT THE EDINBURGH ROYAL MATERNITY HOSPITAL IN THE YEARS 1909-1915.

By J. W. BALLANTYNE, M.D., F.R.C.P.E.,

PHYSICIAN, EDINBURGH ROYAL MATERNITY HOSPITAL; LECTURER ON MIDWIFERY AND GYNAECOLOGY, SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH, ETC.

(Continued from p. 236.)

Autumn Quarter, 1914.

The autumn quarter of 1914 saw 40 patients pass through the prematernity ward. Of these women, 7 were admitted for "convenience," and in this year "convenience" meant generally that these expectant mothers were the wives of Reservists and Territorials who had been summoned to the colours on the outbreak of the war. Even in these cases, however, it was a comfort to be able to make certain by actual pelvimetry that the pelvis was normal and the chief bodily systems healthy. Seven other women were kept in the ward on account of pelvic contraction; in 5 of them induction of premature labour was carried out, 1 was sent home as the date of induction was not due for some time, and in 1 (on whom it had been necessary to perform pubiotomy before) there appeared to be a permanent enlargement which permitted the natural delivery of a living child. In one of the induction cases living twins were brought into the world, but both died when two days old; in 2 the child lived, and in the other 2 it perished (in one instance antenatally and in the other after birth). In all these induction cases it was a great advantage to be able, daily if necessary, to test whether the head could engage in the pelvic brim by means of the Müller manoeuvre; thus the best time for induction could be chosen. There was one other woman upon whom induction was performed, but in her case the operation was carried out because of the large size of her previous babies, causing their intranatal death; a living child weighing 7 lb. was successfully delivered and survived.

An interesting case was that of a woman whose previous four children had all been dead-born. She was sent in because she was becoming melancholic. For four weeks she was kept in hospital and her various functions regulated. At the delivery the cord was round the neck and arms, but a living and surviving child was born and the melancholia rapidly disappeared. Two other women were admitted on account of melancholia. One of them had albuminuria and suffered from condylomata of the vulva, but her blood gave a negative Wassermann reaction; the albuminuria was treated and she was safely delivered of a healthy infant. The other patient had signs of pyelitis

but was delivered normally, and the only sign of mental trouble after labour was shown by the fact that she had got out of bed one night and burst the sutures which had been put in to close a small perineal tear. Two other cases of albuminuria received dietetic treatment, etc., in the ward, and both were successfully delivered and had living and surviving infants. Another patient, in addition to the one named above who suffered from melancholia, was believed to be the subject of pyelitis, and she certainly exhibited some of the signs and symptoms thereof; but she was very discontented in the ward, and went home at her own wish before her delivery.

Hyperemesis Gravidarum complicated by Pyelitis.

This was the only case which terminated fatally to the mother. The woman was a 2-para, 21 years of age; her previous pregnancy and labour had been normal. On admission, when in the seventh month of gestation, she was pale, had marked carotid pulsation in the neck and in the external jugular vein, a small and rapid pulse, but regular and with no diastolic murmurs, and systolic bruits could be heard in all the cardiac areas. The heart was enlarged, especially to the right side. The only heart symptoms were faintness and giddiness if she suddenly assumed the erect position. There was an irritable cough, troublesome at night, and to it was ascribed the vomiting; the examination of the lungs revealed harsh breath sounds but no other anomalies. Before admission she had been seized with numerous rigors, by pain over the right kidney, and by sickness and vomiting. She was treated for pyelitis by her own medical man, but the vomiting and pain over the kidney continuing, he sent her into hospital. There was a trace of albumin in the urine, and a culture of the *Bacillus coli* was obtained from it. She had a temperature of 102.4°, and a pulse-rate of 120. She was put to bed, and an enema was given; milk diet was ordered, and she was given cystopurin and potassium citrate for the renal condition and two kinds of sedative cough mixture, but the latter remedies had to be stopped because of increased sickness.

All the symptoms, save the vomiting, disappeared, and even the sickness was improved. Three weeks after admission she passed into labour, and was delivered of a macerated fetus weighing 4 lb. 6 oz. The placenta was very friable and had numerous infarcts in it. Her recovery proceeded rapidly; she was able to eat and enjoy ordinary food, but on the fourth day of the puerperium she suddenly became blue in the face, sat up in bed for a few seconds, and fell back dead.

The post-mortem examination by Dr. Drennan revealed a dilated heart with a thin-walled right ventricle, emphysema of the upper lobes of the lungs, but no embolism, healing septic nephritis of the right kidney, septic endometritis, and toxic changes in the other organs.

There were two other cases of vomiting. In one of these the woman gave birth to a macerated fetus and recovered; in the other the hyperemesis (at the third month) was controlled by treatment, and after a fortnight's stay in hospital the woman returned home well and with her pregnancy continuing. There were two instances of diarrhoea, in both of which a few days' treatment in the hospital sufficed for cure, and the women went out, their pregnancies uninterrupted. There was also a severe case of

Gastric Ulcer.

The patient, a 1-para of 24 years, was in hospital for eleven weeks in all; at the end of the eighth week she gave birth to a living male child, weighing 8 lb. 2 oz., and notwithstanding many dangerous times (on one of which she had a temperature of 106° and a pulse-rate of 136), she recovered and was able to leave the hospital. Her child also thrived well. Her case will probably be published separately, as it was one of much interest. It was the most anxious one during the quarter.

The remaining cases may be summarized as follows: Two heart cases, one of which resulted well for both mother and child, whilst in the other abortion had to be induced with the loss of the fetal life; a case of epilepsy, in which, after a week's stay in the ward, the mother returned home to await her confinement; a marked case of chorea gravidarum in which treatment with large doses of calcium chloride for a fortnight was sufficient to enable the woman to return to her home (the pregnancy continuing); a case of phlebitis affecting both legs, in which after six weeks' stay in hospital labour came on with the birth of a living child weighing 9 lb. 10 oz., and in which there was a threatening of a return of the phlebitis in the puerperium; 2 cases of cystitis—one accompanied by a threatened abortion—in both of which the patient was able to leave the hospital relieved (pregnancy continuing); a case of post-partum haemorrhage in a previous labour, in which there was again haemorrhage, kept in check by an intrauterine hot douche and pituitrin and ergotin; a case of vulvo-vaginitis and urethritis, under treatment

for a month, in which the child was born prematurely and succumbed a few days later; a case of spurious pains, in which twins of the same weight, which survived, were born four days after admission; a case of injury to the abdomen in which the fetal heart for a time was 180 per minute and the movements very active; and a case of miscalculation of the date of delivery or possibly of post-mature labour. There was, finally, a very interesting case of a woman who possessed only one kidney, and upon whom the phenolsulphone-phthalein test was carried out and gave so satisfactory a result that it was decided to allow the pregnancy to proceed. This case also will probably be published separately.

As a result of prematernity work in the autumn of 1914, 40 mothers passed through the ward, of whom 39 recovered or left relieved, their pregnancies continuing, whilst one—the case of hyperemesis, dilated heart, and pyelitis—died from heart failure in the puerperium. Of the 29 mothers who remained in hospital for delivery there were 31 infants born (twins twice); 23 of these were living at birth and survived, whilst 4 were born dead and 4 more died a few days after birth. Eleven mothers left to be confined in their own homes.

Autumn Quarter, 1915.

The patients who received prematernity treatment in the autumn quarter of 1915 were more numerous but perhaps less interesting than in any previous year. In all they numbered 44; but one who was sent in as a pregnancy was found to be really a case of pseudocyesis, and thus the pregnant patients were reduced to 43. No less than 9 of them were admitted for causes which are difficult of definition, but which may best be denominated "convenience," including under that word poverty, homelessness, desertion by husband, and minor troubles. One of them, a girl of 16 years, was kept in the ward, as it was possible that medico-legal proceedings might be instituted after her delivery.

No case of eclampsia was dealt with in the prematernity ward (there were 8 cases of eclampsia during the quarter, but none of them entered the hospital until labour was in progress), but there were 9 women who were treated on account of marked albuminuria with pre-eclamptic symptoms. They were not the only albuminuric patients who received treatment, but they were the only ones who got it before delivery. Of the 9, 5 were confined in the hospital during the quarter, 3 of them having living and surviving babies (one with a harelip and cleft palate), and two expelling dead fetuses. Three went out of hospital with their condition much improved, and with pregnancy continuing. The other albuminuric was still in hospital at the close of the autumn quarter; she was confined prematurely about a month later, and died immediately after the third stage; there was no post-partum haemorrhage, but her symptoms resembled those of "shock." She had exhibited marked signs of hypothyroidism during her pregnancy. She and two others of the albuminuric patients had had eclampsia in a previous confinement. Her baby (premature) died soon after birth.

The patients admitted for "convenience" and for albuminuria constituted 18 out of the total of 43. The causes for which the remaining 25 were admitted differed very widely. There were 3 cases of hyperemesis; in all of them treatment was so satisfactory that the mothers were able to return to their homes, their pregnancies proceeding normally. There was also a case of vomiting late in pregnancy in a very anaemic woman; but under treatment (iron, etc.) she was safely delivered of a living and healthy child, which weighed 6 lb. 9 oz. There were 3 cases of threatened abortion in which the miscarriage was staved off, and one in which, although the abortion was prevented at the time, it occurred a month later. There were two instances of hydramnios, in one of which the membranes were artificially ruptured and a macerated fetus was expelled; whilst in the other the same treatment resulted in the premature birth of twins, who did not long survive birth. The two mothers did well. Three women were in the ward on account of pelvic contraction; in one of them pregnancy was allowed to go to the full term, and I performed Caesarean section with a happy result for both mother and child; in the other two premature labour was induced, and whilst one of the infants survived, the other died in a few days. One pregnant

woman was admitted because in previous gestations she had given way to drink in the last month; she was kept out of temptation's way in the hospital, and both she and her infant did well.¹ Another woman was admitted on account of a sharp attack of *Bacillus coli* infection of the urinary tract; she had had a retroversion of the gravid uterus which had been replaced accidentally before admission; both she and her child did well. In 2 cases the cause of admission was *ante-partum* haemorrhage; in the one ("accidental haemorrhage") a month's residence in the hospital was followed by the birth of a healthy child, which survived its birth, and in the other, after ten days' rest in the ward, the mother was able to go home, her pregnancy continuing normally. In 6 other cases the cause of admission to the prematernity ward was severe constipation (1), oedema of the labia (1), cystocele and prolapse (2), and vaginitis (2); in all a good result was obtained—4 of the women were delivered of living children and the other 2 were able to return home with their pregnancies continuing.

Two other cases remain to be referred to:

Heart Disease.

One was that of a delicate primipara, who spent several longer and shorter periods in the ward; she suffered from recurring attacks of faintness and of actual syncope, and auscultation revealed a systolic aortic murmur. She was more or less under treatment for the whole quarter, and she continued to attend the hospital until November 23rd, when she was safely delivered of a healthy child (6 lb. 12 oz.), and both mother and child did well.

Cerebellar Tumour.

The other case was that of a primipara, a married woman, who was suffering from the effects of a cerebellar tumour. She was in the ward when I came on duty on July 1st and her condition was deteriorating fast; indeed, before her delivery occurred she became quite blind and deaf; she gave birth to a living healthy child on July 5th, but died on the eighth day of the puerperium. Although so helpless when her infant was born, she was evidently able (by the look upon her face) to tell what had happened, and it was a touching sight to see her holding the baby in her arms.

The results of the prematernity work in the autumn of 1915 may be summarized as follows: Of the 43 pregnant women 12 left the hospital cured of the trouble for which they had been admitted and continuing their gestations, and 31 were delivered in the hospital, of whom 29 made good recoveries and 2 died, one being the patient with the cerebellar tumour and the other being the albuminuric patient who had in a previous labour suffered from eclampsia. The 31 mothers who were confined in the hospital gave birth to 32 children (twins once), of whom 24 left the hospital alive, 4 were macerated at birth, and 4 (all premature) died a few days after birth.

Table showing the Main Results of the Prematernity Work during the Autumn Quarter for the past Seven Years in the Edinburgh Royal Maternity Hospital.

Years.	No. of Cases.	MOTHERS.			INFANTS AND FETUSES.		
		Lived.		Died.	Alive.	Dead.	
		Undelivered.	Delivered.			Ante-natal.	Post-natal.
Autumn of 1909	32	7	24	1	16	1	2
1910	29	12	17	1	14	2	1
1911	26	5	20	1	16	7	0
1912	36	11	25	1	17	17	3
1913	32	4	26	2	21	5	4
1914	40	11	29	1	24	4	4
1915	43	12	29	1	24	4	4
Totals	238	53	177	8	131	47	18

With regard to the 8 maternal deaths, 2 only (those due to croupous pneumonia and acidosis) really occurred while the patient was in the prematernity ward; the remaining 6 all took place after delivery, and 2 of them after my quarter on duty in the hospital was over; at the same time they were all, save the cases of croupous pneumonia and cerebellar tumour, due directly or indirectly to the state of pregnancy (hyperemesis, acidosis, albuminuria with hypothyroidism, phlebitis, and gastric ulcer).

The number of fetal deaths is high—47 out of 196—but it must be remembered that I have included all the abortions (and one was a triplet miscarriage), for every abortion is really a fetal death; and I would also emphasize the serious nature of so many of the maternal states. The number of infants who perished after birth (including premature births) is not, I think, large when all the circumstances are taken into consideration; it was 18 out of 149 who came into the world alive. Fifty-three pregnant patients (out of 238) left the hospital with their pregnancies continuing, and there is reason to believe that most of them ended happily, although details were not always available; the conditions for which they had been admitted and treated were generally of the nature of threatened abortion, excessive vomiting, accidents (falls, etc.), varicose veins, diarrhoea, retroversion of the uterus, cystitis, and spurious pains. One of the most striking results of the prematernity work was the treatment which it was possible to give to 31 mothers suffering from well-marked albuminuria. In only one of these cases did eclampsia develop, and that was in one of the 1909 patients before I had learnt that more than dietetic management was necessary. None of these patients died whilst under my care; but one in which there was a strong element of hypothyroidism ended fatally in the third stage of labour in the succeeding quarter.

CONCLUSIONS.

The following conclusions may, I think, safely be drawn regarding prematernity work in a maternity hospital:

1. A prematernity department is an essential part of a properly-equipped maternity hospital, and it ought to consist of a pregnancy ward, antenatal clinics, and of prenatal nurses (in the extern work).

2. Among the good results coming from it may be reckoned the saving of lives (maternal and infantile), the relief of maternal suffering, the possibility of supervising antenatal hygiene, and the teaching of the normal and abnormal conditions of pregnancy both to students and to post-graduates.

3. The maternity hospital which has such a department will probably have a higher death-rate, for it will inevitably attract to itself cases of a very grave type; but these patients must be treated somewhere, and they will have a far better chance of recovery in the prematernity ward with adequate nursing and skilled medical treatment than in their own homes.

4. The diseases which will be specially benefited by prematernity treatment will probably be albuminuria, eclampsia before the supervision of labour, hyperemesis, chorea, acidosis, threatened abortion cardiac complications, anaemia, chlorosis, hydramnios, phlebitis, pyelitis, and the *ante-partum* haemorrhages before the onset of labour; but the ward will also offer advantages to patients waiting for the induction of premature labour on account of pelvic contraction or previous dead-births from any cause. Less common indications for admission will be found in melancholia, alcoholism, jaundice, gastric ulcer, myxoedema, mucous colitis, phthisis, recurrent abortion or fetal death, haematuria, injuries, etc.; and, indeed, many other uses for the ward will be found after its opening.

5. Further benefit will accrue from the establishment of a well-equipped laboratory, in which the finer methods of clinical investigation can be carried out, as well as by the securing of the services of a pathologist skilled in the special morbid anatomy of the fetus, embryo, placenta, membranes, and liquor amnii.

REFERENCE.

¹ Alcoholism and Antenatal Hygiene, *British Journal of Inebriety*, 1915, xlii, p. 87.

ACCORDING to the *Riforma Medica* the total number of legally qualified doctors in Italy is 22,705, a proportion of 6.3 to 10,000 of the population of the country. The number of foreign practitioners is about 130. Of these some 85 hold an Italian degree which gives them a general right to practise; 25 who have no Italian licence can practise only among patients of their own nationality, and 20 who hold diplomas from British licensing bodies are entitled to practise under the reciprocity agreement between the two countries.

Reports of Societies.

TRENCH NEPHRITIS.

At a meeting of the Sections of Medicine and of Pharmacology and Therapeutics of the Royal Society of Medicine, on February 15th, Dr. LANGDON BROWN opened a discussion on trench nephritis. He said that acute nephritis was not a common disease in civil practice; at St. Bartholomew's Hospital, with an average annual admission of 7,000 medical cases, there were in five years only 26 cases of acute nephritis in men of military age. Whereas dysentery and typhoid had dogged most campaigns in the past, acute nephritis usually had not. It was very rare in the South African war, but in the American civil war there was a very considerable outbreak, which assumed epidemic proportions between March, 1862, and March, 1863. Throughout that war there were 14,117 cases, and it was interesting to recall that the military conditions resembled those of the present war. There was the dash forward of the Confederates, which was checked and followed by prolonged trench warfare. The epidemic in the British Expeditionary Force had not reached such dimensions, but up to the end of June, 1915, there had been 1,062 cases, and they had not been diminishing since. Reports from Vienna showed that the enemy were also affected by the disease, which started about the same time as in our army, and as in the American civil war—that is, in March. Exposure as a cause was negated by the facts of the rarity of the disease in South Africa and in the Russo-Japanese war, and also because it was not until the weather began to get warmer that the disease assumed epidemic proportions. A climatic cause would not explain an epidemic such as that in the American civil war, which lasted twelve months and did not recur in subsequent years of the war. Various other causes, such as the water supply, chlorination of the water, intestinal toxæmia, and acidosis had been suggested, but could be excluded. Only a few cases could be explained as an exacerbation of chronic nephritis. The French army surgeons had suggested that the epidemic was due to a suppressed form of scarlet fever, and it was interesting to note the immunity of the Indian troops from nephritis, as the inhabitants of India enjoyed comparative immunity from scarlet fever. Although this theory would not stand examination, it was important to note that the urinary and pathological changes in trench nephritis and scarlatinal nephritis were closely similar. Chemical tests showed that, as in a nephritis of infective origin, trench nephritis was glomerulo-tubular in distribution, and this had been confirmed by *post-mortem* examination in some of the few fatal cases. As to the nature of the infection, cultures from the blood, fauces, and urine had yielded no positive bacteriological results, but Dr. Mackenzie Wallis had obtained suggestive, though not conclusive, evidence of an ultramicroscopic filter-passing virus by injecting the urine, which had been passed through a Berkefeld filter, into rabbits and monkeys. A severe illness was produced after a latent period of eight days, which would exclude a mere chemical cause, and corresponded to the incubation period which had been observed clinically. Wassermann's reaction was positive in about one in every three cases. This did not mean that such patients were necessarily syphilitic, as other animal infections would produce a positive reaction. A filter-passing infection was believed to be animal in nature. A number of the cases had had symptoms of fever and malaise before the nephritis, but usually oedema was the first symptom. Shortness of breath had been a striking and very common symptom, starting at the same time as the oedema, but ceasing after a few days. Bronchitis was common, and a fair proportion of patients had complained of sore throat. Great reduction in urinary secretion was not so common as in ordinary acute nephritis, while great variations in the daily quantity were not uncommon. Haematuria sometimes continued long after all signs of active inflammation had subsided. Leucocytes, epithelial, granular and fatty casts were usually found in the urine, though blood casts and fatty casts were rare. Uraemic convulsions occurred occasionally, but generally yielded to free venesection. A considerable proportion of the cases recovered speedily, but if this did not take place, the duration might be prolonged

for weeks or even months. The albuminuria often became intermittent before it ceased altogether. Relapse was not uncommon. Some, no doubt, were becoming chronic nephritides, but the immediate mortality was very low. He gave reasons for believing that the epidemic was due to a specific infection, probably resembling, but not identical with, the organism causing scarlet fever. He thought that animal inoculation experiments with material from recent cases were advisable, and suggested that much might be learnt as to the mode of infection by the preparation of maps showing the exact distribution of the cases.

Sir WILLIAM OSLER said that the disease had not been described before, with the exception of the records of the cases which occurred during the American civil war. Its main clinical characters were those of ordinary acute nephritis, and, like it, started quickly, and usually without any previous disorder. There were, however, certain peculiarities. The oedema was transient, and usually local; general anasarca was rare. Dyspnoea was unusually prominent. Slight fever was present in a few of the cases which had returned to England, but it was probable that it was more common in the earlier stages. The rapid improvement, which coincided with the disappearance of the dropsy, was remarkable, and an apparent restoration to good health with persistence of the urinary changes and a high blood pressure was common. Severe uraemic symptoms had occurred without dropsy and with only high blood pressure. Cases had been admitted showing albuminuria with casts and blood in the urine, but without a history of dropsy, the condition being detected only by urinary examination. Although it was the rule for the cases to end in recovery, yet death occurred in not a few. Of 113 cases at Taplow, 2 ended fatally; of 30 at Paignton, 2 more; and 1 was fatal at Oxford. It appeared that a larger proportion of deaths occurred than recent papers indicated. A *post-mortem* examination had been made in 3 of these cases. In one a typical large milky-white kidney had been found, identical, except for the absence of injected stellate veins, with the classical example described by Bright. There were no signs of fatty degeneration. In the second case acute nephritis had been superimposed on an old nephritis. In the third case the patient died from intercurrent pleuropneumonia. The kidneys were sclerotic, but there was also marked recent tubular and glomerular nephritis. The remaining 2 fatal cases were accompanied by uraemia and ended rapidly; no necropsy had been made. It was a good clinical rule that if in acute nephritis the urine did not become free from albumin by the end of the twelfth week the probability was that the condition would become chronic. There was evidence of persistence of the nephritis among those patients at Taplow who had been ill for more than ten weeks. Nine out of 14 had a high blood pressure. In 6 of the older patients high blood pressure was accompanied by commencing arterial changes. In 10 of the 14 the urine was of a low specific gravity. For these reasons he feared that many sufferers from this condition would never have a complete restoration of the functions of the kidney.

Dr. F. W. ANDREWS exhibited microscopical sections from six cases which he had examined histologically. He had only been able to obtain one example at an early stage. In that instance sudden death had followed cerebral haemorrhage, but the clinical evidence of a recent acute nephritis was fairly conclusive. Histologically he had found nothing indicative of acute nephritis, but only such changes as he would have expected to find in a man who had died from apoplexy. The remaining were specimens obtained from examples of typical acute nephritis, and were representative of severe trench nephritis. All showed changes in the glomeruli, tubules, and interstitial tissue. In the glomeruli was the usual proliferation of the epithelium of the capsule; in the tubules, degeneration and desquamation of the epithelium. Fatty changes were slight or absent. Some cellular infiltration occurred in the interstitial tissue, the infiltrating cells being chiefly leucocytes, whilst plasma cells were absent. This corresponded with the condition of the urine, in which a deposit of leucocytes was noticeable. In one case so many polymorphonuclear cells appeared in the urine that pyelitis was suspected. One case was an example of old-standing nephritis which had occurred three years previously, and upon which trench nephritis had been superimposed. There was nothing histological to

distinguish trench nephritis from other forms of acute and subacute nephritis. The acute glomerular nephritis of scarlet fever was comparable in all respects with trench nephritis. He had failed to find any micro-organism in the urine or kidneys.

Dr. MACKENZIE WALLIS, who had carried out pathological investigations to determine, if possible, the true nature of the condition and its origin, spoke first of the value of estimating the diastatic output as an index of the efficiency of the renal tubules. In no disease was this as low as in renal disease. In trench nephritis there was a definite relation between the severity of the case and the diastase content of the urine. Since the ferment was secreted by the tubules its diminution in the urine of these cases indicated that the tubules were affected, and the degree of its diminution indicated the extent of the damage. The test had also value in prognosis; diastase might still be diminished in the urine after the albumin had disappeared. There was no evidence of any protein being present in the urine other than serum albumin and serum globulin, as in ordinary nephritis, and they were present in the usual relative proportions. The amount of albumin varied from a trace to 0.3 per cent. as estimated by Esbach's method. Microscopically, casts were constantly present and were chiefly of the hyaline variety. There was a relative excess of white blood corpuscles, which was also characteristic of scarlatinal nephritis. In some cases there was retention of nitrogen even after the diastase excretion had returned to normal, and this had to be taken into consideration in determining the ability of the patient to return to duty. The nitrogen content of the cerebro-spinal fluid had been found to be raised when uraemia was present. In investigating the origin of the condition he had first considered the possibility of a co-existing intestinal toxæmia, but found that the ethereal sulphates in the urine were not in excess, but markedly diminished. With mineral poisoning the diastase content was also subnormal, but careful examination of the urine had failed to reveal the presence of any mineral poison. To discover a possible parasitic origin he had resorted to inoculation experiments on animals, using blood serum, cerebro-spinal fluid, and catheter specimens of urine. The urine was shown to be remarkably toxic, but the chemical characters of the toxic agent had not been determined. Apparently there was a powerful toxin circulating in the blood and excreted in the urine. He had repeated the experiments with scarlatinal nephritis, but obtained no results which were comparable. In the trench nephritis cases an illness was produced without exception on the eighth day. Two animals had died with albuminuria six days after injection, but *post mortem* there was no histological evidence of nephritis. Urine which had been heated to 55° C. produced no illness when injected, but an unheated filtrate did.

Dr. R. G. ABERCROMBIE, who had been working in France, had seen over 500 cases in the acute phase. In their early stages they presented the characteristics of acute nephritis of modern severity. The most constant symptoms were headache and dyspnoea. The blood pressure showed diurnal variations of from 30 to 60 mm. of Hg, the morning reading being low and the evening high. The bouts of dyspnoea were nearly always nocturnal, and it was therefore open to question whether they were due to the rapid rise of blood pressure. At the beginning of the disease fever was present, the temperature being about 101° F. In about half of the cases there were premonitory symptoms, these in order of frequency being bronchitis, pains in the back and limbs, and abdominal pains and vomiting. Tonsillitis was exceedingly rare, but laryngitis and tracheitis were more common. Convulsions had occurred in 14 cases, and for their treatment lumbar puncture and venesection, especially if accompanied by saline infusion, seemed valuable. Mania was met with in 4 cases, amaurosis in 3. Fundal changes were not seen in any during the first three weeks. Two occasional associations, herpes and bilateral parotitis, supported the contention that the condition was of infective origin. A well defined group could be separated in which the symptoms suggested pyelitis, cystitis, or prostatitis; in them oedema, fever, and rise of blood pressure did not occur, but casts might appear in the urine. Of some 500 cases 4 ended fatally, 1 before the end of the first week. The kidneys of this case showed but slight macroscopic changes. Microscopically the lesion

was essentially one of the tubules, with some interstitial change. The spleen was enlarged and the tracheal mucous membrane granular. As regards the causation, the cases were scattered, but occurred chiefly at the front and in definite small epidemics. The men were more liable to the disease in certain areas. His own impression, based on the clinical symptoms and the characters of the epidemic, was that the disease was infective.

Reviews.

THE PHYSICAL CHEMISTRY OF PHYSIOLOGY.

From time to time it has happily been the practice of eminent physiologists to write illuminating works in which their outlook upon the methods and philosophy of physiology is detailed and justified. Some twenty years ago, for example, this was done by Verworn, whose general account of physiology was written from the point of view of a protozoologist, and took the cell as the unit of physiology. Professor BAYLISS has now, in turn, published a most interesting and suggestive account of the *Principles of General Physiology*,¹ in which he regards the science from the point of view of a molecular physical chemist.

Such a mechanical point of view is, of course, not a novelty. Historically speaking, physiology has always been a highly derivative branch of science. In the main its progress has depended for inspiration upon other sciences, particularly physics and chemistry, or, less happily, upon abstract philosophy. As regards the great question as to the nature of life, during the last three centuries natural science has made such progress that all physiologists have been able to adopt a definite standpoint here and to build upon one of two foundations. Either they could assert that life was a mere succession of physical and chemical processes, or they could state that living organisms were ruled and animated by a new power, vital force. In this way two schools of physiology have grown up side by side, the mechanical and the vitalistic. Among the vitalists may be mentioned van Helmont, the school of Montpellier in the eighteenth century, and Johannes Müller and Bunge in the nineteenth century; among the mechanists, Descartes, the iatro-physical and iatrochemical schools of the eighteenth century, and to mention one out of the many more recent writers, Max Verworn. But there are still many vitalists among us who believe that the known laws of physics and chemistry are not adequate to explain the phenomena of living matter. Professor Bayliss is a confirmed mechanist, and, as has been said already, he sets out to explain vital phenomena in terms of mathematical physics and chemistry. The enormous progress that has been made in our knowledge of the laws of physical chemistry during the last thirty years, and in the study of the chemistry of colloids during the last decade, makes it possible for him to go a long way towards the mathematical exposition and solution of the problems of "vital force" with a thoroughness that was, of course, completely impossible for his iatrochemical and iatromechanical predecessors.

The book consists of twenty-four chapters, followed by a complete and up-to-date bibliography of eighty pages and by indexes. The first third of the text is devoted to an elaborate and most lucid exposition of the chemical and physical forces upon which all the processes of physiology depend. Surface action, the colloidal state, the permeability of membranes, osmotic pressure, electrolytes and their actions, the properties and functions of water, are all considered in turn. Wherever possible, Professor Bayliss discusses the energetics of the systems or modes of activity with which he deals; he is also at great pains to reduce all modes of chemical or physiological activity to mathematical formulas and equations, with the use of integration, log *e*, and the like. In the same way he makes free use of the Helmholtz theory of double electric envelopes, stepping boldly on ground where only the skilled mathematician and physicist will be able to follow him. Succeeding chapters of the book deal with such subjects as catalysis, nutrition, secretion, digestion, the phenomena of muscle and nerve in various aspects, receptor organs, the action of light, oxidation, respiration,

¹ *Principles of General Physiology*. By W. M. Bayliss, M.D., F.R.S., etc. London: Longmans, Green, and Co. 1915. (Roy. 8vo, pp. 870; 259 figures. 21s. net.)

and the circulation of the blood; the last chapter is given to the consideration of hormones, drugs, and toxins.

Throughout this part of the volume Professor Bayliss deals with the general physiology of living tissues rather than the particular case of man; his unit is the ion, the molecule, the disperse phase of a colloid solution, the surface of a membrane or supposed membrane, as the case may be, rather than the cell or the organ as a whole. His knowledge of the physiology of plants enables him to illuminate many of the complex processes of animal life by comparison with the simpler reactions or activities of the vegetable cell; he also makes numerous references to Gaskell's hypothesis as to the origin of the vertebrates. His object everywhere is to show how far the known laws of physical chemistry, using the term in its widest sense, can give an accurate explanation of vital processes in nature. He will have nothing to do with chemical theories or analyses that are incapable of mathematical expression, such as Ehrlich's side-chain theory and toxin spectrum, for example; on the subject of the coagulation of the blood he writes, characteristically:

In point of fact, it cannot be said that it is yet understood. Much of the research done has led to little more than the multiplication of names given to supposed substances held to take part in it, but these have not been isolated as chemical individuals, and the names really refer to aspects of phenomena. . . . As an illustration, I would refer to a paper . . . where we find the following names used as applying to definite substances: fibrinogen, prothrombin, prothrombokinase, anti-thrombokinase, thrombokinase, anti-thrombin, and anti-prothrombin. These are supposed to be present before clotting. After clotting we have: fibrin, thrombin, thrombokinase, anti-thrombin?, anti-prothrombin, anti-thrombokinase, and prothrombin.

Undoubtedly science would gain by the abolition of most of these names and the obscurities attaching to the processes for which they stand. From his own point of view, Professor Bayliss describes the clotting of blood as follows:

The coagulation of the blood is an interaction between certain colloidal systems under the influence of electrolytes, chiefly calcium salts. The intervention of surface action is shown by the accelerating effect of rough surfaces and by the action of lipoids.

In his last chapter, which is one of particular interest to medical men and experimental pathologists, the author gives good reasons for believing that Ehrlich's side-chain theory and chemo-receptors and chemo-therapy must now all go by the board, so far as they claim to give anything like a chemical picture of immunity, anaphylaxis, phagocytosis, the action of toxins and antitoxins, and the like. In their place he gives us physical factors and processes as adsorption, surface action, the permeability of cell membranes, the mutual precipitation or aggregation of inorganic colloids when mixed with protein solutions; and he entertains considerable doubt as to the alleged specificity of many of the reactions met with in the province of immunity. Oponins, for example, may act only by adsorption and consequent changes in surface tension. Refreshing doubts also are cast upon the alleged specificity of many enzymes; Professor Bayliss holds that Emil Fischer's "lock and key" simile is, as a matter of experience, inappropriate here, and substitutes for it the kinetic view of velocities of reaction as more in accordance with facts.

As regards "vital force," his method of destruction is to show that it becomes less and less necessary to physiology in proportion as our knowledge of physics increases. Even so useful a conception as Clerk Maxwell's "sorting demon" appears to find no place in his scheme of intracellular mechanics.

It is impossible to do justice in a brief review to the wealth of learning in physics, chemistry, and physiology displayed by Professor Bayliss in this volume. However abstruse the subject, he succeeds in giving a clear account of it—even the Helmholtz double electric envelope, a conception most valuable in molecular physics, is rendered intelligible to the intelligent reader! His style is simple and not uninteresting; it is plain that his desire is to establish the merits of his own point of view rather than to attack and destroy the theories of rival physiologists, which he always treats with scrupulous fairness. It is possible that the volume would gain by condensation, and that certain points in it are treated with unnecessary fullness. The illustrations are excellent; a special feature of the volume consists in the inclusion of portraits of

the most eminent physicists, physiologists and chemists who have contributed to the progress of the science, and the fact that no fewer than three portraits of the eminent Dutch physical chemist van't Hoff are reproduced may be taken as showing the bent or bias of Professor Bayliss's physiology. The printing is good and the text is singularly free from misprints; the author makes a point of adopting the French rather than the German method of spelling Russian names, very properly, but oddly enough does not apply the method in the case of Metchnikoff.

Professor Bayliss is to be congratulated on the success with which he has applied the methods and mathematics of physical chemistry to the whole range of general physiology. He has developed and extended a new method of attacking old problems that yields most illuminating and suggestive results, and his general plan of campaign may undoubtedly be said to carry us a stage further in the comprehension and analysis of the various processes which result in the phenomena of life. His book should be read by all advanced students of physiology who have occasion or time to think of more than passing examinations. It will also be of great interest to medical men and general readers, equipped with a knowledge of elementary chemistry and physics who are interested in the progress of pure science. It does not in any way take the place of such standard textbooks of physiology as those of Halliburton, Howell, Starling, or Stewart, but it provides the reader with a novel and most valuable philosophy on which to base his fundamental conceptions of the science.

MATERNITY AND CHILD WELFARE.

(Concluded from page 212.)

Commentary on the Official Scheme.

So far we have given a fair account of the official programme, and without commentary. There are certain points that immediately arise for consideration. First, the arrangement with the doctors for the work of the centres. Secondly, the hint of "notification of pregnancy."

So far as the medical staffing of the centres is concerned we may refer our readers to the report adopted by the Representative Meeting of last year. Sections 3, 4, 5, those most pertinent to this, are as follows:

3. That the present scheme of the Board is open to the objection that it is very likely to lead to the establishment of principles and methods which would in the long run vitally alter the present status of the profession, and the relation between doctor and patient to the detriment of both; but that these dangers are not a necessary outcome of the scheme if properly safeguarded.

4. That there would be a tendency under the scheme to the formation of a class of practitioners who will be wholly concerned with the treatment of disease in expectant mothers and in young children, and that almost the whole of actual practice among such patients may be withdrawn from the general practitioner; and that if the medical and surgical treatment of the public is to continue to be (as it should) in the hands of general medical practitioners, aided by suitable opportunities for consultative and pathological assistance, the effect of this must be seriously detrimental to public and professional alike.

5. That, correspondingly, if it be correct that the most satisfactory and valuable form of receiving advice and treatment is by means of the "family doctor," with considerable personal choice as to who that "family doctor" shall be, the scheme would have a tendency to lead away from this to the less desirable method of treatment by one or two officially appointed whole-time practitioners.

The report of the Association has been issued to the clerks and medical officers of some 1,300 sanitary authorities, and already some 600 additional copies have been asked for. But the latest central departmental memorandum does not bear the impress of a consideration of the report. The medical arrangements are left in the hands of the local committees truly, but the first official hint is that the duty should be undertaken by "an officer of the local authority"—that means a "tied" doctor, the servant of an authority, one lacking the healthy experience of free practice with its stimulating competition of ideas—and it probably means a whole-time official. Arrangements with local practitioners are only cited to hint at their difficulties.

"Notification of Pregnancy."

Twice in the latest report this new form of notification is referred to, and once in so many words.

The post-natal work of the Centre will depend for its success on the home visits made by health visitors under the Notification

of Births Act. There is no similar machinery for securing the clientele for an ante-natal centre; and its success will depend on the co-operation of medical practitioners, and midwives, and of any voluntary agencies likely to send expectant mothers for advice to the Centre.

Again,

Some system of notification of pregnancy has been suggested, under the impression that this is a necessary antecedent to the commencement of an ante-natal Centre. Such notifications should not be made unless the express consent of the expectant mother has been previously obtained.

There appears to be something like a sigh of regret in these phrases that there is no such thing as a "notification of pregnancy." And that there is sorrow in the official heart at the lack we may find evidence in the "progressive" measures adopted by two local authorities which have boldly instituted this notification in their areas.

The city of Nottingham appears to be the first authority to attempt the task. We have the official form before us. It is a handsome document the size of a sheet of foolscap. There is a counterfoil. The back of the form is printed with the address of the medical officer of health for the city, and it is the evident intention that the form should be folded over and posted or delivered to him; no provision is made for the sealing of the document.

The main part of the form reads as follows:

CITY OF NOTTINGHAM.

NOTIFICATION BY A MIDWIFE OF HER ENGAGEMENT TO ATTEND A CONFINEMENT.

To the MEDICAL OFFICER OF HEALTH, Guildhall, Nottingham,

I hereby give you notice that I have to-day been engaged to attend

Name of Mother

Address

Expected date of Confinement

Is the patient a primi ara? ...

If not:

Number of previous pregnancies

Number of miscarriages

Number of premature births

Number of still-births

Number of children born alive

Number of children still living

Has any child suffered from ophthalmia? ...

Has the patient had a previous difficult labour? ...

(Signed) Certified Midwife.

Date 191..... Address

Has the mother a complete set of baby's clothes?

Has she at least:

two nightdresses

two pairs of sheets

one waterproof sheet

one dozen diapers

Are the home circumstances satisfactory?

Is the husband in work?

Is the lying-in room suitable?

Is the mother well-nourished?

Are there any signs or symptoms of complications of pregnancy?

Huddersfield has gone one better than Nottingham, the euphemism "notification by a midwife of her engagement to attend a confinement" is dropped, and more than that—from "January 1st, 1916, the said Sanitary Authority will PAY THE SUM OF 26 (TWO SHILLINGS AND SIX PENCE) to each registered medical practitioner and to each registered midwife for each notification of pregnancy received from the said persons."

The official form for notification is nothing so handsome as the Nottingham. It is no more than a letter-card, the inside of which is type-written by a process machine, as follows:

COUNTY BOROUGH OF HUDDERSFIELD.

PUBLIC HEALTH DEPARTMENT.

Notification of Pregnancy.

(a) Notified by Date 19.....
(b) that
(c) of

is expected to be confined on or about 19.....

(a) Name of notifier.

(b) Name of expectant mother.

(c) Postal address of expectant mother.

This scheme of notification promulgated by Huddersfield bears so recent a date as December 30th, 1915, so that it is not unreasonable to suppose that it represents what is the most desirable form of procedure and a reflection of the latest views of the Government department concerned.

The immediate questions that arise on a knowledge of these schemes are: What good are they supposed to serve? and, how are they looked upon by the women immediately concerned? Dr. Newsholme's report states that pregnant women commonly engage their midwives to attend them about two months before the date of the expected confinement. From inquiries amongst those who have most to do with the midwives we learn that this is a fair estimate. Formerly the date was earlier, but now there is a tendency to a delay in the booking. The present tendency to delay has been brought about by the maternity benefit of the National Insurance Act; before that came into force poor women joined maternity clubs, and put by a shilling a

week or so whilst "carrying," so as to pay the midwife; they therefore joined their clubs and booked their midwives early. Now the midwife's fee is secured by the maternity benefit, so that there is no necessity for the help of a maternity club, and the booking is delayed.

The midwives fear that such schemes of notification as these will still further delay the booking of their patients, and they rightly point out that any good that can be brought to bear on antenatal development is proportionate to the earliness with which the expectant mother can be seen and advised.

There is another and very strong objection in the minds of the midwives to this scheme. They maintain that antenatal care is most likely to be fostered by improving the knowledge and capability of the midwife, and that this scheme, by the interposition of a visitor between them and their patients, will reduce the sense of the midwives' responsibility. The midwives point out with reason that they are as keenly interested in the health of their women as any one; that their duties are enforced by the stringent rules and control of the Central Midwives Board, and that any possibility for the betterment of the women entrusted to their care would be warmly welcomed by them. What they want, they say, is not more advice—and this is to be the main stock in trade of the maternity centres—but more facilities for the prompt medical treatment of the women they find or suspect to be unfit, and the facilities for treatment of the centres is meagre in the extreme. To refer a sickly pregnant woman for another examination at a strange centre, where again she may be told to go to a doctor for treatment, is not to forward the interests of that woman; indeed, the double trouble and pulling about is likely to sicken her of medical examination, and needed treatment will go by default. Give us, say the midwives, facilities for the proper treatment of our women at the hands of experienced doctors, and antenatal work will grow apace.*

There is another side, that of the pregnant woman. How will she look at this notification of her condition? Pregnancy is a matter both of pride and shamedness with the women, and this is especially so with primiparae, who are the most important from the point of view of any antenatal scheme. Their peculiar condition makes them exceedingly important, and very difficult, personalities, and they are not easily persuaded of the benefit of the advice of "authorized" strangers. The prospects of difficulty with such a scheme, and the very real prospect of frightening off shy mothers from going as early as they should to their doctors and midwives, makes one ask whether the scheme is worth the risk. The scheme does not so much as propose the advantages of the "mothers' kitchens," which prepared good meals for the women at cost price as a seasoning for the same free advice, and, further, showed the women how to cook these nice meals.

On the strict test of logic the scheme is wrongly dated. Antenatal care should begin *before the beginning*. When a woman is pregnant we can, save in a few cases, only tinker at the work of remedying defects in the basket of the coming infant. If we are in earnest for the improvement of the race, why not deal with the basket itself and the fertilizer thereof? We are illogically careful to assure ourselves of the *civil fitness* of the applicants for marriage, and inflict heavy penalties for the transgression of our laws of this fitness. But for the immeasurably more important *physical fitness* of these applicants for marriage we take not the least heed; there is not a hint to them that it should be a matter of thought. No proposal that applicants for marriage should present a medical certificate of their fitness would find favour, but it would not be unreasonable to ask these applicants for a declaration of their physical fitness even as of their civil fitness. It would probably create the demand for facilities for satisfactory medical care, and make antenatal schemes the want of the people instead of leaving them as schemes wanting people. There is nothing outrageous in the suggestion of this declaration of physical fitness; it is no more than a shifting of the strong words of the Anglican marriage service to an earlier and a better date.

* Since this was written we have received a copy of "The Memorial of the Incorporated Midwives' Institute and its Affiliated Associations, representing Practising Midwives in all parts of England and Wales." In this document all the points here referred to are elaborated and emphasized. The memorial has been sent to the Local Government Board.

British Medical Journal.

SATURDAY, FEBRUARY 19TH, 1915.

WOMEN MUNITION WORKERS.

THE Health of Munition Workers Committee has issued two more memorandums—the one on the employment of women¹ and the other on hours of work.² Of these, the former is the more interesting, partly because the subject is more novel. It is well conceived and well written. It is, indeed, a relief to come across an official publication which moves easily and directly, if not always quite succinctly, towards its purpose. There are no parentheses and no lists of things “that may be thought of in this connexion”; it is a piece of humane writing, which frankly tells the reader what the writer or writers wish him to understand. It deals with five matters concerning the health and industrial output of the women workers. Of these far the most important is that treating of periods of employment, for the section on arrangements for rest and meals is really only a subdivision of the first. That the output should stand in direct relation to the health of the workers may seem a truism to medical readers, but by health the Committee means something more than freedom from disease. It means that absence of weariness which makes labour pleasure. There ought and can be in the labour of munition workers all the three great sources of pleasure in work—physical exertion short of weariness, interest in doing well work which it is not quite easy to do well, and the inspiration of a great cause.

The employment of women in factories at night was prohibited for the textile trades by the factory legislation of 1844. It disappeared gradually in Great Britain and also in other countries, and was banished altogether by international agreement from the twelve European countries which signed the Convention of Berne in 1906. This international decision was reached after full examination of reports showing that night work caused deterioration in health due to the difficulty of securing sufficient rest by day, disturbance of home life with its injurious effect upon the children, and diminished value of the work. Though experience has shown that night work is inferior to day work, the necessities of the war have revived the night employment of women in factories, and it is the object of the memorandum to indicate how its evil effects may as far as possible be obviated. As long hours, particularly when worked during the night, appear to be the chief factors in fatigue, it is recommended that in the interests of output and health alike there should be suitable pauses for rest during the working period and adequate cessation from work at each week end, in addition to periodic holidays. The Committee does not go so far as to advise against night work for women in the present emergency, but it insists that the employment of women at night calls for great care and supervision, and that adequate pauses for rest and meals are indispensable. The greater fatigue produced at night is considered to be due partly to the fact that the hours between 3 and 7 a.m. coincide with the period

when, apart from industrial fatigue, vitality is low, and partly to the fact that night workers lack the stimulus of a satisfactory meal, for they appear to have little appetite for a meal which is to be taken between 1 and 3 a.m.

There are two main systems of arranging the hours of labour: under the one there are two shifts of twelve hours, and in the other three shifts of eight hours, but there is also a third, and from every point of view most pernicious system, that of overtime, where one shift is worked from thirteen to fourteen hours. It results in undue fatigue, illness, and bad time-keeping. From the report of the mission appointed by the Director-General of Recruiting for munitions work on the output of munitions in France, it may be gathered that in that country, where the results have been extraordinarily good, the two-shift system is general, but there is a long break, averaging one hour and a half, at noon, which, it is stated, enables the women to look after the meals and comfort of their children at home. Owing to difficulties of transit and housing the plan does not work well in this country; the only houses workers can obtain are often at a considerable distance, and the trains and tramcars are overcrowded. The Committee has no hesitation in recommending that the three-shift system without overtime should be adopted wherever a sufficient supply of labour is available, that for women and girls a portion of Saturday and the whole of Sunday should be reserved for rest, and that the periodic factory holidays should not be omitted. Apart from general considerations which would lead to the conclusion in favour of the week-end rest, it has been found as a matter of experiment to be of so much importance in maintaining health and vigour that it has been reinstated by employers who had taken it for work at the beginning of the war.

A difficulty not easily surmounted is the arrangement of the changes of shifts—the change, for example, from day to night, or vice versa. It does not seem to have been as yet satisfactorily overcome. In the memorandum on hours of work, which applies to both sexes, the Committee expresses the opinion that on physiological grounds much is to be said for infrequent changes of shifts. In any case it is recommended that the change should be effected by dropping one or more shifts, and not by working for one and a half, and that the worker should have a time for rest before and after the change of shift. With regard to breaks during the day, it appears that work, as a rule, commences at 6 a.m., with breaks of half an hour for breakfast and an hour for dinner. At some factories, however, work begins at 7 a.m. or 8 a.m., the workers being expected to have had their breakfast before arrival. The objection to starting at the later hour is stated to be that, if the worker breakfasts before leaving home, the distance to be travelled to work may necessitate a very long period between breakfast and dinner; this objection is partly overcome in some places by allowing a tea interval, and it would seem that it might be met also, as it is in France, by an earlier midday meal. The Committee concludes that there is no real objection to the system of starting later, but there is some reason to think that the matter might have been put rather higher than this, for the experience of some factories in peace has been that the work done before breakfast is not good.

In dealing with the effect on women of lifting and carrying heavy weights, and violent physical movements in the operating of machines, the memorandum states that a simple appliance or

¹ Cd. 8185. Price 1½d.

² Cd. 8186. Price 1½d.

the alteration of a movement has often been found to modify an objectionable feature, even when it does not altogether remove it. Instances of this will be found in the Notes on the Employment of Women on Munitions of War, also issued by the Ministry this month. The publication is in a very unusual form for an official document, and consists largely of reproductions of photographs of women at work making shell bodies, working in the general machine shops and on air craft, and making shell fuses. It is a most striking and convincing picture-book.¹

BLOOD STAINS.

In India the medico-legal expert is very frequently confronted with stains of blood upon garments, utensils, and objects of every kind produced as evidence against the accused in criminal cases. The Imperial Serologist at Calcutta² has recently recorded his results of the examination of 6,566 articles suspected to be blood-stained in 2,643 such medico-legal cases, made in a period of thirty-one months. The cases were almost entirely charges of murder, homicide, or assault in some form or other. Blood-stained articles of about 140 varieties were submitted for examination, half of them being classified under the single heading of wearing apparel; the others varied in nature from carts to nail-parings, umbrellas to toddy-tappers. Blood stains were found on over 5,000 of these articles; in many others it appeared as if blood stains originally present had been washed away so thoroughly as to leave insufficient blood for spectroscopical or microscopical recognition. In 36 cases the blood was non-mammalian; in 90 more it was mammalian but not human, but either ruminant, equine, canine, feline, or cameline, the diagnosis being made by the use of the appropriate precipitating antisera obtained from fowls after immunization with the red blood corpuscles of the various mammals concerned. For the microscopical examination of a blood stain the author uses Vibert's solution³ as the best of all those with which he is acquainted. For the microspectroscopical examination he employs a 10 per cent. solution of potassium cyanide and a yellow solution of ammonium sulphide, blood being recognized by the appearance of the two absorption bands characteristic of cyanhaemochromogen.

The possibility of mistaking ape's blood for human blood alleged by German writers is denied by Lieutenant-Colonel Sutherland, on the practical grounds that the simian antiserum does not give the human blood reaction within the specified time limit, and that the ape is not a domestic animal in India, and so is not immediately available when its blood is required to obscure or divert the path of avenging justice.

Numerous stories are related to show the skill which certain Indian intriguers devote to the manufacture of evidence against their personal foes and neighbours. For example, at Madura a religious feud existed between two castes, the Nadars and the Naickers. The former decided to start a riot in which one of their number should be killed, so that the murder might be attributed to the Naickers. "At the conclave held a Nadar proposed that his wife, whose conduct was not all that it should have been, should be the victim. Another suggested that his wife, who had deserted him, should be chosen. A third proposed that his mistress should be chosen, as she had no

children and no relatives to avenge her death. This woman was beaten to death after a telegram had been dispatched from the nearest telegraph office to the district authorities to the effect that while worshipping at the temple she had been murdered by the Naickers. At the temple a sheep was slaughtered to 'prove' this. One of the accused persons was found to have blood on his loin cloth, and the stains were found to be due to human and sheep's blood." The accused, however, were acquitted for want of corroborative evidence. In another case "a man swore before a magistrate that he had been beaten by certain persons, and showed a wound on his head and a cloth stained with blood which, he said, had flowed from the wound, which had been caused by a blow from a *lathi*. The assistant surgeon reported that this wound had been caused by a sharp instrument and not by a *lathi*, and the cloth was found by us to be stained with non-mammalian blood alone. The man was tried for fabricating false evidence and sentenced to two years' rigorous imprisonment."

The medico-legal examination of alleged and true blood stains has given rise to an enormous literature, as may be seen in a recent volume⁴ on the medico-legal importance of stains in general. Lieutenant-Colonel Sutherland's experience with blood stains of many varieties has clearly been very large. The office of Imperial Serologist at Calcutta must be anything but a sinecure, however much lightened by the interest of tracking out the hidden motives of passion or revenge animating the criminals concerned. It is apparent, too, that the medical expert in India is treated no better by the Bench than he is in this country.

PROFESSOR PAVLOV.

PROFESSOR PAVLOV, whose death in St. Petersburg, where he had so long taught, was announced on February 12th, was not only one of the greatest physiologists of his day, but is to be numbered amongst the most distinguished men of science that Russia has produced. The work by which he first became generally known related to gastric digestion, and especially to its nervous mechanism. He showed the immense importance of the nervous element by his experiments on what he called "appetite secretion." The sight of food at once caused gastric secretion more copious and active than the actual presence of food in the stomach. The effect is produced through the vagus. In meat there are some bodies already existing which provoke secretion, and similar bodies may be produced in the other foods by the act of digestion itself, so that when once started, as by the appetite secretion, the process is kept up. He showed, on the other hand, that pancreatic secretion is little, if at all, affected by appetite, its chief excitant being the acidity of the chyle. More recently he had turned his attention to the investigation of the higher nervous functions, a subject on which he delivered an address (a translation of which was published in our columns at the time) before the last International Congress of Physiologists (Groningen, September, 1913). For twelve years he had devoted himself to the experimental study of reflex action and the prime function of the nervous system that concerned the formation of new reflexes, which, in the process of adaptation of living creatures to their surroundings, must be formed. He gave good reasons for believing that a well-developed conditional reflex has a definite cerebral localization, and incidentally threw a curious light on the physiology of sleep and hypnosis. He concluded that the experimental evidence afforded proof that the cerebrum is

the organ for the analysis of sensation and for the construction of new reflexes and new interpretations of sensations. As in the case of the stomach, his method of investigating the higher functions of the brain was new and in his hands had already yielded results of the first importance. Professor Pavlov was born in 1849.

THE ROYAL MICROSCOPICAL SOCIETY.

In taking the chair for the first time as president of the Royal Microscopical Society on January 19th last, Mr. Heron-Allen said that the prime duty of the society was to record the progress of microscopic research and to encourage the development of microscopic technique and appliances. In pursuance of this policy, he, with the assistance of Messrs. C. F. Rousselet, A. Earland, and T. H. Court, made a communication to the meeting of the society on February 16th on the progress and development of vision and definition under the microscope. The subject was illustrated by the exhibition of a series of thirty-one microscopes from the society's collection, ranging from the primitive instrument of Leeuwenhoek (c. 1673) to Messrs. Beck's prismatic binocular. The compound (uncorrected) microscopes ranged from that of Culpeper (c. 1710) to Jones's "most improved" (1798); the achromatic instruments commencing with that of Dellebarre (1777). Under twenty-two of the instruments (all those for which the society possesses contemporary objectives) the foraminifer *Poly-stomella striato-punctata* (Fichtel and Moll), the first protozoan ever figured (by Hooke in 1665 and by Leeuwenhoek in 1702), was exhibited, mounted in the manner adapted to, and contemporary with, the instruments. A series of early books illustrating magnified objects was also exhibited, ranging from Gesner (1565) and Hoefnagel (1592) to the middle of the eighteenth century. The definition of the early microscopes of Leeuwenhoek (1673), Wilson (1702), and Joblot (1716) is poor, but the object is easily identifiable. The double (or compound) microscopes (1710-98) maintain a more or less dead level of slightly improved definition, especially when a back lens is present, but there is always a good deal of colour in the image. The reflecting microscopes of Amici and Cuthbert (1827) did away with this defect to a notable extent; the instrument of Dellebarre (c. 1777) in the society's collection is not in working order, and was, therefore, not available for comparison. The great improvement, leading gradually to the perfection attained in the present day, became first apparent in the achromatic instruments of Charles Chevalier (1820-30). The main object of giving this demonstration was to promote the issue by the society of a comprehensive history of the microscope from the earliest times to the present, illustrated by the instruments in the possession of the society and in private collections. The development of the microscope, and especially of its accuracy and definition, has played a large part in the advance of scientific medicine during the last century, and an accurate microscope is an indispensable part of the outfit of a bacteriologist. Mr. Heron-Allen in his presidential address said, on the authority of Professor Herdman, that Edward Forbes, the father of oceanography, was indirectly instrumental in introducing the study of histology and microscopic structure into medicine, because Professor Hughes Bennett, to whom he assigned this honour, had been a fellow student of Forbes (1841). Without for a moment seeking to take one leaf from Hughes Bennett's laurels, we yet venture to hesitate a doubt whether he is entitled to all the credit in this respect. It is true that Bennett, during his studies in Paris, acquired skill in the application of the microscope to medicine, and that soon after his return to Edinburgh in 1841 he commenced lecturing on histology, and gave a series of microscopical demonstrations in physiology and pathology and the diagnosis of disease, and also

held classes for microscopical demonstration. But we believe that before 1841 William Sharpey had already begun to give microscopical demonstrations in London; he had been appointed professor of anatomy and physiology in the University of London in 1836, and had begun to lecture upon physiology and minute anatomy. He was the possessor of what was for that day a very good microscope, and he used to give evening demonstrations. The microscope was mounted on a round table attached to a long arm pivoted at the centre; it travelled on a broad brass band let into the table. This table existed a few years ago at University College, and may probably still be seen there. Sharpey arranged a specimen under the microscope and passed the instrument to his next neighbour, and so it went the round of the table until it came back to the demonstrator, who then adjusted another specimen. Sharpey published his paper on ciliary motion in 1830 while still a teacher in the extramural school in Edinburgh.

THE ITALIAN MEDICAL SERVICE.

In a recent debate in the Italian Senate Professor Pio Foa of Turin said that at first, in the hurry of mobilization, not a few officers of the medical service of the Italian army had been assigned to posts for which they were not specially fitted. Now, he said, this had been in large measure remedied. Very large demands had been made at the beginning of the war on the younger men, who were all sent to the front, where they had been ever since, and he asked that arrangements should be made for their relief from time to time. He said that already thirty-four medical officers and eight students had been killed and a large number wounded. This was due to their appreciation of the importance of giving first aid to the wounded with the least possible delay. The savagery of an enemy who fired on ambulances, stretcher bearers, and medical officers must also be taken into account. Yet in Italy the army doctor was not regarded as a combatant, and for him there was no hope of promotion for military merit. There was also the question of rank. Every doctor called up for active service had to begin with the rank of lieutenant, though the Minister for War had yielded to a demand that teachers should rank as captains; still it not infrequently happened that university professors had their own former assistants put over their heads with the rank of major. Again, a large number who had been declared unfit when exemption was comparatively easy to obtain and were not afterwards called up for further examination were given comfortable billets at home. Foa next dealt with the proposal to establish a university at San Giorgio di Nogaro where accelerated courses were to be given to students of the fifth and sixth years who should be specially examined at the end of the course by their teachers. These courses might serve if it was decided to create medical sub-lieutenants for military service, but he did not see how certain special subjects such as midwifery and gynaecology could be taught in the field. The Minister for War, Signor Zuppelli, said in reply that he had always held that the medical service was one of the most important factors in bringing the war to a successful end. He knew well that the medical officer insisted on being at the post of honour beside the soldier. The complaint as to want of promotion for war merit was, he asserted, unfounded. The project for a so-called field university was designed not to enable students of the fifth and sixth years to obtain a degree, but to pass certain special examinations. The ultimate fate of the proposal must depend on the judgement of the superior council of public instruction and the cabinet. The idea was to establish a course in some suitable place near the front where a moderate number of students could be assembled; the material available there would be much more abundant than was to be found in any university.

RAT-BITE FEVER.

RAT-BITE fever is a specific infectious disorder of rare occurrence following on the bite of a rat. It has been observed in Europe, Asia, and America, but it is commoner in Japan than elsewhere, being called "sokodu" in that country. It has been caused, also, by the bite of a ferret and of a South African squirrel. It was first brought into general notice by Miyako in 1899, when he reported eleven cases of his own; it appears that fifty-three cases were reported in 1915, with a single autopsy. In 1914 the bacterial cause of rat-bite fever was isolated for the first time, and named the *Streptothrix muris ratti* by its discoverer, Schottmüller. Quite recently Dr. F. G. Blake, of Boston, has described¹ a case, ending fatally, from which he isolated the organism described by Schottmüller. The disease is rarely fatal; not so, however, in Dr. Blake's case. The patient, a healthy woman of 67, was bitten on the tip of the right index finger while taking a rat out of a trap. The wound was not severe, and was washed in hydrogen peroxide solution. Two days later signs of lymphangitis appeared in the arm; the wound was opened and dressed, and in four days the inflammation and pain had entirely subsided. A fortnight later she had a severe rigor and was sent to hospital, where she sank and died in sixteen days. A blotchy macular and maculo-papular rash appeared on the limbs and thorax, as is common in this disease; a moderate leucocytosis was present, with irregular fever. The blood gave a pure culture of the streptothrix mentioned above, and Dr. Blake gives details of its cultural characteristics and several photomicrographs of its growth. The organism was only feebly pathogenic for rabbits and white rats, and not pathogenic for guinea-pigs. At the necropsy the streptothrix was again recovered from the blood; it had caused an acute ulcerative endocarditis of the mitral valve, with perforation; infarcts were found in the spleen and kidney, with local subacute inflammatory lesions in the myocardium and the abdominal viscera that appeared free from streptothrices, and were presumably toxic. The patient's serum developed a high power of agglutinating the streptothrix. As Dr. Blake points out, the mortality of the disease is about 10 per cent., though it often incapacitates the patient for a considerable time; death may occur early from profound toxæmia, or later from the development of severe nephritis. The organism is described as slender and filamentous, forming a mycelium, and, later, chains of cocci, bacilli, or rods, spindles, and clubs may appear. It stains readily, and is Gram-negative and a facultative anaërobe.

SLEEPING SICKNESS IN PRINCEIPE.

SLEEPING SICKNESS is known to have been on the increase among the native population of the West Coast of Africa for at least a hundred and sixty years. The islands of Principe and San Thomé—lying off the Bight of Biafra, colonized mainly from the Gaboon and the Congo, for many years used as an entrepôt for slaves destined for Brazil—both of them Portuguese colonies devoted to the growing of cocoa, have suffered very severely from sleeping sickness during the last forty years. Since 1890 the disease has been an insuperable obstacle to the progress of agriculture in Principe. In this island the average annual death-rate from sleeping sickness between 1902 and 1913 was 5.6 per cent., the total death-rate averaging 15.5 per cent., and being over 22 per cent. in the worst years. About a quarter of the total population was found to be infected with the trypanosomes of sleeping sickness in 1907–11. Medical science meanwhile was not inactive; from 1907 onwards about £1,000 a year was spent on atoxyl—annually some 75,000 injections of 10 grains

each were given—as a first endeavour to check the ravages of the disease. A full and interesting account of the physical and geological characters of the two islands, their flora, fauna, and climate, the great advances that have recently been made in their sanitation, and the further steps taken to stamp out sleeping sickness in them, has recently been published in a Portuguese medical periodical by da Costa, Sant' Anna, dos Santos, and Alvares (*Archivos de Hygiene e Pathologia Exoticas*, vol. v, March 30th, 1915). Lieutenant-Colonel J. A. Wyllie, F.R.G.S., has provided an English translation.¹ One of the first steps was to lessen the area of breeding ground for the tsetse fly, *Glossina palpalis*, the chief of the blood-sucking flies that infect man with the trypanosome of sleeping sickness. Another step was to exterminate the trypanosome carriers among the wild animals inhabiting the island. In 1911 the campaign was reinforced by various legislative enactments. An official sanitary brigade was organized, and was able during the next few years to carry out its duties with greater or less degrees of success; jungles were felled, extensive works for the drainage of swamps were undertaken; sentence of death was passed on all pigs, dogs, and civet cats in the island, and we read that while some 2,000 pigs perished unofficially, the official brigade accounted for 2,500 more, leaving no more than 20 survivors in August, 1914. Over 2,000 dogs were killed by gun or hatchet, and over 2,000 civet cats. It is noted that there is no reason, at present, for supposing either that *Glossina palpalis* ever feeds on the blood of the civet cat, or that the animal is ever a carrier of trypanosomes; none the less the order, "Off with its head," was carried out. Many monkeykeys have been killed, chiefly on account of the damage they do in the plantations; they do not seem to form part of the routine diet of *Glossina*. From 1907 onwards great efforts to destroy *Glossina* have been made, largely by the method of making the plantation workers wear on their backs dark-coloured cloths smeared with viscous preparations, to which the flies stick when they alight. In 1911 and 1912 over 400,000 *Glossinas* were killed in this way; in 1914 the fly was almost extinct in the island. As a further precautionary step, the blood of all the domestic animals in Principe was thrice examined for trypanosomes. Experiments showed that it was practically impossible to sterilize the infected horses, mules, donkeys, or oxen by repeated injections of 30 grams of atoxyl; hence all the infected animals were slaughtered. Great care was taken to detect all the trypanosome carriers among the inhabitants of the island, to isolate them, and to treat them with atoxyl in the form of double injections of 10 grains at forty-eight hour intervals every ten or fifteen days, for a period of at least four months, until repeated negative examinations of the blood for trypanosomes had been made. The cost of this campaign between 1911 and the middle of 1914 was over £30,000. Its results are described in detail, and appear to have been most satisfactory; naturally, as is pointed out, a number of stringent sanitary and other regulations will have to be maintained if the island is to be kept free of sleeping sickness. Descriptions are given of the forms of the trypanosomes found in Principe, the haematophagous insects found there, the intestinal flagellates of the *Glossina*, and the trypanosomes of the tabanid flies. The Portuguese Medical Mission that has been so successful in its efforts to suppress sleeping sickness and to improve the general hygiene of Principe is to be congratulated upon the thoroughness with which it has carried out its work. The colonial system of Portugal has not infrequently been made the object of severe strictures in England: one may doubt whether any country could show a better record of a campaign waged against a relentless disease than is to be found here.

WASSERMANN'S REACTION IN CHRONIC
DISEASES OF THE LIVER.

It has long been recognized that a positive Wassermann's reaction may be yielded by the serum of a patient who has not had syphilis, but is suffering from such diseases as scarlet fever, leprosy, pellagra, yaws, and a few others. Drs. C. Verdozzi and L. Urbani¹ extend this list by the inclusion of certain chronic disorders of the liver. After giving a full account of their technique, which is precisely that described by Wassermann himself, they give a tabular and also a detailed account of 26 patients with chronic hepatic affections in whom no history or signs of syphilitic infection could be obtained. An account is also given of 27 control cases, patients with either some acute disease of the liver or bile ducts, or with acute or chronic disease of some other organ, but free from any suspicion of syphilis. Not one of the 27 controls gave a positive Wassermann reaction. But a positive reaction was obtained in no fewer than 20 of the 26 patients with chronic hepatic disease. Nine of the 26 were suffering from primary or secondary new growths of the liver, and 8 of these gave a positive reaction; in 7 the reaction was complete. The remaining 17 had one or another form of cirrhosis of the liver, and Wassermann's reaction gave a positive result in 9 of these, while in 3 more there was fixation of the complement even in the absence of antigen. The authors remark that Boas failed to find a single positive reaction in 59 cachectic patients with malignant disease; possibly, they suppose, because the liver was little involved in these cases. The authors state that jaundice is not in itself a cause of a positive Wassermann reaction; jaundice was present in 13 of their 26 patients, and 6 of the 13 gave a negative reaction, as was also the case with all the 6 patients in the control series who were jaundiced. They note that the reaction was more often incomplete in hepatic cirrhosis than in the cases of hepatic neoplasm.

RESTRICTIONS ON THE SALE OF LAUDANUM.

THE recent action of the Council of the Pharmaceutical Society, in adding to Part I of the Poisons Schedule all preparations of opium containing 0.75 per cent. or more of morphine, puts an end to a somewhat anomalous state of things which has existed for the last thirteen months. Until the *British Pharmacopoeia* of 1914 came into force on January 1st, 1915, laudanum, or tincture of opium, contained 0.75 per cent. of morphine, and was therefore included in Part II of the Poisons Schedule, and could be sold by any qualified pharmacist without restriction, provided it was labelled with its name, the word "Poison," and the name and address of the seller; only preparations containing 1 per cent. or more of morphine were in Part I, so that they could not be sold unless the purchaser was personally known to the seller or was introduced by some one known to both, and after making an entry, in a book kept for the purpose, of the particulars of the sale, the purpose for which it was required, etc., which entry had to be signed by the purchaser. In the *British Pharmacopoeia* of 1914, however, the strength of the official tincture of opium was raised to 1 per cent. of morphine, while the synonym "laudanum" was retained, and the tincture therefore passed automatically into Part I of the schedule. This placed pharmacists in a somewhat difficult position; if called on *de novo* to dispense or supply tincture of opium or laudanum, the new tincture alone could be supplied and the regulations of Part I must be complied with, but in dispensing prescriptions written when the old *Pharmacopoeia* was in force, obviously the tincture of the old strength must be used, and in selling laudanum to persons who had previously been accustomed to buying it, it would have been dangerous to supply an article one-third stronger than formerly, even though the requirements of Part I as to signing the Poison Book were complied with.

In order to prevent divergence in the methods adopted by different pharmacists in dealing with this situation, the Council of the Pharmaceutical Society passed a resolution recommending that "when laudanum is asked for the 1914 preparation should be supplied, and the Poison Book signed; but when the 1898 preparation is demanded, care should be taken to label it accordingly, and the attention of the purchaser should be called to the fact that it is the 1898 preparation." The Privy Council submitted this resolution to the General Medical Council, and the latter body expressed the opinion that the limit of strength for preparations of opium which can be sold without the Poison Book being signed should be 0.75 and not 1 per cent. This recommendation was duly passed to the Council of the Pharmaceutical Society, as the body charged by law with the duty of amending the Poisons Schedules, and has now been acted upon by it. The present position, therefore, is that any one purchasing "laudanum" without indicating the preparation of the 1898 *Pharmacopoeia* will receive the 1 per cent. tincture, while those accustomed to the older and weaker preparation can obtain it by asking for the 1898 tincture, but in both cases the Poison Book must be signed and the full requirements of Part I complied with. It is certainly desirable that the sale of so dangerous a substance as laudanum should be hedged round with all the restrictions required by the law, and the inclusion of both tinctures in Part I will remove the possibility of obtaining it without complying with these restrictions by demanding the tincture formerly official.

INFECTIOUS DISEASES IN SCHOOLS.

THE common specific infectious fevers, particularly, perhaps, diphtheria, have been the bugbear of the masters and mistresses of schools and colleges for many decades. Small educational establishments have been ruined before now by the occurrence of a fatal case of diphtheria among their boarder pupils, although it may have been obvious that the authority responsible for the health of the pupils was in no way to blame for the catastrophe. Nowadays both parents and public opinion are apt to be so well informed, not to say censorious, in the matter of the spread of infectious fevers among school children, that it is of the utmost practical importance to the medical men, headmasters, and matrons who may be in charge of them that there should be some standard authority to lay down the rules and regulations whereby this spread may best be prevented. This authority is furnished in the excellent *Code of Rules*¹ issued by the Medical Officers of Schools Association. The first edition appeared in 1885; the latest and seventh edition was issued a few months ago. Beginning with a list of the periods of quarantine and of the isolation of the infected, the *Code* gives brief but thorough directions for the general hygiene of schools and their sanatoriums, the precautions that should be taken to avoid the entry or return of pupils who may be infectious, and the steps that must be taken to prevent the spread of such fevers as diphtheria, measles, scarlatina, and the like when they have broken out in schools. Enteric fever, cerebro-spinal meningitis, and poliomyelitis are not included in the *Code*; three appendices contain forms of certificates that may prove useful, the law as regards notification, and practical directions for disinfection. The *Code* is briefly and clearly written. It should be in the hands of all medical men and trained nurses who have to do with children with the specific exanthems, and it may be cordially recommended to the attention of the ever-widening circle of schoolmasters, school managers, and parents who are so directly interested in minimizing the incidence and harmful effects of the acute specific fevers.

GUNSHOT FRACTURES OF THE JAWS.

The treatment of gunshot fractures of the jaws is at the present time attracting a good deal of attention. It is both difficult and important. Part of the difficulty arises from the fact that the parts are almost always infected, and it is practically impossible to free them from infection. Another difficulty, in the case of the lower jaw, is that of safely bringing the fragments into proper position and maintaining them for a sufficient length of time. Unless this can be done union will almost certainly take place in a faulty position, and the use of the jaw in speech and mastication will be seriously interfered with. The distressing nature of the deformities that may be produced, particularly perhaps when the fracture involves the upper jaw, is another reason which makes these injuries worthy of study. We are glad, therefore, to be able to publish this week a set of papers on the subject, in which general and dental surgeons have acted together, with great advantage to their patients. A discussion on war injuries of the jaws is to take place at a meeting of the Section of Odontology of the Royal Society of Medicine on Monday, February 28th, and an exhibition of dental splints, models, radiograms, photographs, and apparatus illustrating the subject, will be open from Tuesday next, February 22nd, to Monday, February 28th (from 11 a.m. to 5.30 p.m. each day). Any member of the profession who can contribute is invited to communicate with the honorary secretary of the Section, 1, Wimpole Street, W.

THE news of the death of Sir William Turner, principal and vice-chancellor of the University of Edinburgh, will be received with a sense of personal loss by thousands of friends and old pupils in every part of the British empire. He was in his 85th year, but had been attending to his university work with his usual alertness and acuteness of mind until about a week ago; he then began to suffer from gastric trouble by which his strength was rapidly exhausted. We hope to publish a biographical notice in an early issue.

A MEMORIAL to Florence Nightingale in the crypt of St. Paul's Cathedral was unveiled by the Queen on February 14th. It is placed on the wall of the archway that leads from the tomb of Nelson to that of Wellington. The Archbishop of Canterbury, in addressing Her Majesty, said that the success of Florence Nightingale was due to the fact that to a buoyant faith, a courageous hope, and a large love were added penetrating judgement, potent personal influence, and almost unrivalled administrative skill. The memorial, which is of white marble, showing a half-length portrait, is the work of Mr. Walker, the sculptor of the statue unveiled last year in Waterloo Place.

THE annual meeting of the Royal Medical Benevolent Fund Guild will be held at the London Mansion House on Monday next, at 3.30 p.m., under the chairmanship of the Lord Mayor. The Guild supplements the assistance given by the grants of the Royal Medical Benevolent Fund by personal services, by gifts of clothing, and in other ways. The number of cases with which it is asked to deal is increasing, and the Guild appeals to the public as well as to the medical profession for support. Subscriptions may be sent to the treasurer, Mrs. Scharlieb, M.D., 149, Harley Street, W.

THE Gynaecological and Obstetrical Societies of Latin and German Switzerland have decided to hold a combined meeting once a year under the name of the Société Suisse de Gynécologie. It will be held alternately in Latin and in German Switzerland. The first meeting is fixed for September next, and will be held at Lausanne under the presidency of Dr. Henneberg, President of the Latin Society.

THE WAR.

WOUNDS OF THE HEAD AND BRAIN.

Dr. W. v. BRUNN¹ states that he enjoyed exceptional facilities for studying wounds of the head, as the field hospital which he commanded was barely 3 kilometres behind the front, and he was able to keep his patients there as long as he wished. Even after they were drafted elsewhere, he was able in practically every case to keep in touch with them, and to learn the late effects of his treatment. Altogether he deals with 297 cases of wounds by projectiles. The face was wounded in 104 cases; 4 of these patients died early owing to extensive shattering of the bones and laceration of the soft tissues. Among the 193 cases of wounds of the head in which the face escaped, there were 74 cases in which the bones of the skull were injured. Among these, again, the brain escaped direct injury in 6.

WOUNDS OF THE BRAIN.

Of the 68 patients whose wounds extended to the brain, 42 died and 24 recovered; the fate of the remaining 2 was unknown, as they had to be transferred elsewhere within the first week. Among the fatal cases were 17 patients whose condition was too hopeless for any operation, and who died in a few hours. Two other patients wounded early in the war died on the fifth and eighth days respectively, no operation having been performed. Twelve patients admitted to hospital in a desperate condition were operated on, and died within a day. Eleven patients were operated on, and died after six to fifteen days, death being due to encephalitis in 5 cases and meningitis in 6. Among the 24 patients who recovered were 8 who had been wounded by bullets passing through the skull (*Durchschüsse*), and who were not operated on. The remaining 16 patients, who recovered, were operated on (trephined). Altogether Dr. v. Brunn saw 17 cases of wounds of the skull in which the bullet had escaped (*Durchschüsse*), and among them 7 died and 10 recovered. Among the 11 wounds of the skull in which the bullet remained in the body (*Steckschüsse*), there were 8 deaths and 3 recoveries. There were also 40 cases of tangential wounds of the skull, with 27 deaths, 11 recoveries, and 2 cases whose fate was unknown. The high proportion of cases admitted moribund to hospital was explained by the brevity of the interval between the infliction of the wound and the admission of the patient to hospital. This class of case was not seen by surgeons only a few kilometres further from the front, and thus it was that these surgeons were apt to be misled as to the prognosis of bullet wounds of the brain.

TREATMENT OF WOUNDS OF THE SKULL.

Treatment of wounds of the skull was instituted as early as possible, but only in two cases was it necessary to operate when the bullet had passed in and out of the skull. Both these patients recovered in spite of shattering of the bone and prolapse of the brain. Operations were frequently undertaken when the bullet remained in the skull, but when it was not found at once no extensive search was made for it, for fear of injuring the brain and exciting encephalitis. Necropsies performed in such cases almost invariably showed that the projectile could not have been removed without serious injury to the brain. Dr. v. Brunn had learnt to defer extensive operative measures for this class of case till weeks had elapsed, when the external wound had healed and facilities were available for operating under aseptic conditions and x-ray control. On the other hand, tangential wounds of the skull were operated on in practically every case, and whenever there was the slightest suspicion of brain injury. At these operations the borders of the wound were cleaned and partially excised, the margins of the bones were trimmed, and loose fragments, some of considerable size, were extracted from the brain or from the space between the skull and the brain. In two cases in which recovery ultimately occurred pieces of the skull, almost as large as the palm of the hand, were removed. When the loose fragments of bone had been removed, loose sterile mull was lightly applied to the wound. The wound

¹ *Deut. med. Woch.*, November 11th, 1915.

was kept open, the greatest care being taken to avoid compression of the brain by sutures or primary plastic coverings. During the first weeks of convalescence every effort was concentrated on the avoidance of infection; and, apart from stringent asepsis, the most important measure was the avoidance of every mechanical irritation, notably pressure on the brain. Irritation thus produced almost invariably provoked more or less severe oedema.

PROLAPSE OF THE BRAIN A REASSURING SIGN.

Dr. v. Brunn repeatedly observed that those patients did well in whom prolapse of the brain developed early and continued some time. He also noticed that what he called the pedicle of the prolapse became united to the surrounding margin of the skull by a fine adhesive membrane, which formed a barrier between the interior of the skull and the surface of the prolapsed brain, often septic and necrotic. When the necrotic layer of the prolapse sloughed off, the brain sank again, but did not retract completely within the limits of the skull, as it had become secured to the margins of the skull and dura. The surface of the brain thus left exposed was first covered by a delicate, rose-coloured layer of granulation tissue, which ultimately gave place to epithelium growing from the margins of the wound. Even when the prolapsed portion of brain was larger than a fist it finally shrank to small proportions, retracting automatically as the wound healed. Dr. v. Brunn took care not to exert any pressure on the prolapse, as the assumption that it needed pressing back into the cavity of the skull was incorrect. It was, however, necessary to protect the brain by a plate or a plastic operation at a later stage when the wound had completely healed.

THE SYMPTOMS OF ENCEPHALITIS AND MENINGITIS.

When, after the first two or three days, the brain showed no further tendency to prolapse, and began instead to sink back into the interior of the skull and to become discoloured, encephalitis had supervened; and the patient, who had gradually been losing consciousness, snuffed out like a light. For this condition there was no remedy. If meningitis occurred, the temperature began to rise before other serious symptoms developed. This warning was an indication for lumbar puncture, which yielded cloudy fluid under high pressure. When this was the case, lumbar puncture should be repeated daily and sometimes even twice a day, if the patient's condition became alarming and the fever increased. Though Dr. v. Brunn had lost many patients in spite of this procedure, it had saved the lives of many others, even after they had developed all the classical signs of meningitis. In all his cases he gave urotropin, and he was prodigal in the use of hydrogen peroxide, which he applied to the whole of the wound. In a most desperate case, in which the lateral ventricle had been perforated, he instilled hydrogen peroxide daily. In spite of a bed sore as large as two hands, the patient, though soporose for days, ultimately recovered, but left hemiplegia remained. Though opposed on principle in other fields of surgery to frequent changes of dressings, Dr. v. Brunn had soon learnt that wounds of the brain required daily changes of dressings—at any rate, for the first weeks. In many cases more or less extensive areas of hyperaesthesia were found associated with injuries to the head. The most varied paralyses were also observed; but Dr. v. Brunn threw no new light on the relations between these conditions and the particular brain lesion by which they had been provoked.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

LIEUTENANT-COLONEL HEW RAMSAY DUFF, of the Canadian Army Medical Corps, was reported to have died in France in the casualty list published on February 11th. He was born at Kingston, Ontario, in September, 1857, the son of the late Lieutenant-Colonel John Duff, police magistrate of that city, and was educated at Kingston grammar school and at Queen's University, Toronto, where he took the degree of M.D. in 1884. He had been connected with the Canadian Army Medical Service throughout his career, was President of the Army Medical Corps Board of Survey

for Ottawa and district, acted as medical officer of the Quebec tercentenary celebrations in 1908, served in the South African war with the Canadian contingent from 1899 to 1901, gaining the Queen's medal with four clasps, and held the Canadian long service decoration. He attained the rank of lieutenant-colonel on July 27th, 1904.

Miss W. S. Coates, V.A.D., serving with the British Red Cross, is reported in the casualty list published on February 12th as having died on service in the Mediterranean.

Killed in Action.

Captain George Seymour Stritch, 6th Service Battalion, Connaught Rangers, was killed in France on February 7th. He was born in Dublin in 1878, the son of the late George Seymour Stritch, K.C., educated at Trinity College, Dublin, and in the schools of the Royal Colleges of Surgeons of Dublin and Edinburgh, and took the Scottish triple qualification in 1895, also the L.A.H. Dublin in 1902, and the L.M., with a special certificate in gynaecology, at the Rotunda Hospital in 1904. After qualifying, he filled the posts of assistant medical officer of the Argyll and Bute Asylum, and resident medical officer of the Lock Hospital, Dublin. He subsequently settled in practice in Dublin, where he was anaesthetist to the Incorporated Dental Hospital, Ireland, and honorary surgeon to the Actors' Association, Actors' Union, and Music Hall Artists' Association. He had also been examiner in midwifery, gynaecology, medical jurisprudence, and materia medica to the Apothecaries' Hall, Ireland, had written several papers on venereal disease, and was the inventor of a prolapse pessary. He had served as a Captain in the Volunteers, and when the war began received a commission in the 15th Battalion Durham Light Infantry, from September 23rd, 1914, being subsequently transferred to the Connaught Rangers. He was a prominent Freemason, and a cousin of Sir Edward Carson. In 1910 he married Lilian, daughter of Canon Ford, and leaves two children.

Wounded.

Captain A. R. S. Alexander, I.M.S., Mesopotamia.
Captain N. R. Rawson, R.A.M.C. (temporary), France.
Captain H. Dunkerley, R.A.M.C. (temporary), France.
Lieutenant E. Doherty, R.A.M.C. (temporary), France.
Lieutenant N. A. Scott, R.A.M.C. (temporary), France.

DEATHS AMONG SONS OF MEDICAL MEN.

Holmes, Philip Lawton, of the King's Royal Rifles, killed on the Western front on November 25th, 1915, was the second son of Dr. James Holmes of Whitefield, Manchester.

Richardson, Thomas Charles, Captain Special Reserve, Royal Engineers, elder son of Dr. T. A. Richardson, of Clifton Park Road, Clifton, late of Combe Martin, North Devon, and formerly of Croydon, killed in France on February 5th. He got a commission as Lieutenant in the Reserve, R.E., in June, 1914, and was promoted to Captain in July, 1915. He was serving with the 185th Company, R.E., when he, with another officer, was killed by the enemy exploding a mine.

Singh, B. P. and B. M., lost in the *Persia*, on December 30th, were the sons of Lieutenant-Colonel B. J. Singh, I.M.S., Inspector-General of Prisons, Bihar and Orissa. They had been at St. Paul's School, and were returning to India.

Turton, Cecil William, Lieutenant 6th Battalion, Royal Sussex Regiment, younger son of James Turton, F.R.C.S., of Brighton, accidentally killed at Brighton on February 4th, aged 21.

MEDICAL STUDENTS.

Marshall, John Morrice Maitland, Lieutenant 4th Essex Regiment, who died of wounds on October 23rd, 1915, was a student at St. Bartholomew's Hospital.

NOTES.

SCOTTISH WOMEN'S HOSPITAL.

THE staff of the first and second Scottish Women's Hospital Units arrived in London on February 12th, after two months' detention as prisoners of war in Austria and Serbia. The members are:—*First Unit*: Drs. Davidson and McDougall; Miss Bowhill (matron); Sisters Fletcher, Brown, Scorgie, Skae, Mortimer, Hissey, Gibson, Pettigrew, Smith, Jones, and Lamb; Miss Madden (chauffeur), Miss Duke (x-ray operator), and Misses Gregory, Hare, and Lees (V.A.D.). *Second Unit*: Drs. Alice Hutchison, Laura Hope, Sybil Lewis, Agnes Proctor, and Charles Hope; Miss Jack (administrator); Miss Philp (matron); Miss Gordon (sanitary inspector); Nurses Bayne, Carter, Caton, Donovan, Dow, Duguid, Ellis, Evans, Gordon, Hall, Hamer, Hart, Kilty, Oldfield, Pinder, Richards, Saunders, Walmsley, Williams, and Wilson; Misses Nicholls, Kerr, M. Fraser, A. Fraser, and Tebbutt (orderlies).

Ireland.

IRISH WAR HOSPITAL SUPPLY DÉPÔT.

THERE are a number of War Hospital supply dépôts in Ireland, where some thousands of ladies make hospital requisites for the wounded. The provincial dépôts work in conjunction with the central dépôt in Dublin, which is affiliated with the Joint Committee of the Red Cross and St. John Ambulance Brigade. The several Irish dépôts are supported entirely by voluntary contributions and all the workers are voluntary. There is a register of over 1,000 voluntary workers at the central dépôt, and the average daily attendance for the past three weeks has exceeded 180. These ladies, working under trained instructresses, who are the most expert of the voluntary workers, make all classes of many-tailed and roller bandages and swabs, special boots for soldiers suffering from "trench feet," and pneumonia jackets. The Dublin dépôt has undertaken the making of surgical dressings for the Committee of the Dublin Salesmasters' Association, which has charge of the administration of the proceeds of the All-Ireland Farmers' sale, which was specially earmarked for dressings, etc., for men in the trenches in the fighting centres. Several bales of dressings on this account have already been sent to Salonika and Flanders. The first grant to the dépôt from this committee was £250, and a further sum of £750 has recently been handed over. By purchasing the materials in large quantities, and having the dressings made by voluntary workers, a saving of at least 25 per cent. is effected. Considerably over 12,000 articles were made at the Dublin dépôt during January. Sphagnum moss is largely used in the manufacture of swabs, and its suitability for this purpose, when properly cleaned, is now widely recognized. Last week Her Excellency Lady Wimborne, accompanied by Major-General Friend, Commander of the Forces in Ireland, visited the central dépôt in Dublin, and after an inspection of the various workrooms, expressed their keen appreciation.

Scotland.

AT the annual meeting of the Glasgow Maternity and Women's Hospital on February 10th it was stated that altogether 3,645 cases, including 1,650 indoor cases, had been treated during the year. Among them were 563 wives of soldiers and sailors. Sir George Beatson, in moving approval of the reports, said that the nation was awakened to the fact that there must be an economy in infant life. Though there were differences of opinion, he thought all were agreed that the organization for dealing with the matter must be built upon the basis of the Notification of Births Act. The Countess of Eglinton, in seconding, said that the expected result from the Insurance Act of a diminution in the mortality among mothers had not come about. This was not due to destitution, because wages were higher and separation allowances adequate. The causes appeared to be carelessness, love of pleasure, dirt, neglect, and maternal ignorance.

At the meeting of the Glasgow School Board on February 10th Dr. Grant Andrew gave a summary of the report on the medical inspection of school children for the year ending July 31st, 1915. Though there was no improvement in the number of underfed and ill-clad children as compared with the previous year, the totals were small and compared favourably with those for 1909-10. Medical treatment was given for ear, eye, teeth, and skin diseases. The proportion of children with decayed teeth was still very high; 5,487 out of 24,611 medically examined had five or more decayed teeth. There were 1,971 cases of rickets, but the percentage of children with rickets and rickety deformity admitted to schools for the physically defective showed a gradual diminution.

In his annual report Dr. G. Douglas McRae, medical superintendent of the Ayr District Asylum, stated that the admissions of men (70) were 14 under the average of the past twenty years, while those for women (71) remained practically the same. Alcoholic excess was present in

41 per cent. of the men and 22 per cent. of the women, as compared with 47 per cent. and 14 per cent. respectively last year. Little influence ascribable to conditions arising out of the war was to be observed among those admitted.

The report presented to the annual meeting of the Glasgow Royal Infirmary on February 14th stated that the capital fund had, for the second year in succession, been seriously encroached upon. The charges amounted to over £5,000 a month, and even after applying the net amount received by way of legacies, donations, etc. (£13,000), it had been necessary to withdraw over £15,000 from capital account. The managers appealed for increased financial support to the extent of at least an additional £30,000 a year. The number of patients admitted showed a slight increase—from 10,291 to 10,705; the daily average number resident was 741, against 678. The average residence of those treated to a conclusion was 25.5 days, against 23.9. During the year 150 beds had been maintained at the disposal of the naval and military authorities, and had been more or less continuously occupied, without interfering with the ordinary work of the institution. Of the members of the medical and surgical staff, 38, or practically all, hold commissions, R.A.M.C., and 12 are engaged in Red Cross hospitals.

TOLAMINE (CHLORAMINE-T).

THE importance of the contribution entitled "Studies in Antiseptics" (Dakin, Cohen and Kenyon, *BRITISH MEDICAL JOURNAL*, January 29th, 1916), describing the advantages of para-toluene-sodium-sulphochloramide as an antiseptic for irrigating infected wounds, etc., has been recognized by the medical profession, and Messrs. Burroughs, Wellcome and Co. have prepared compressed "soloids" of the substance in two strengths—8.75 and 87.5 grains. The title chloramine-T was suggested by the authors of the paper, but for many years a combination of other medicinal agents has been issued bearing the name chloramine. To avoid confusion, therefore, Messrs. Burroughs, Wellcome and Co. have decided to use the name "Tolamine." The statements contained in the paper by Dr. Dakin and his colleagues as to the strength in which the antiseptic has been found suitable in the conditions mentioned may be summarized as follows:

For irrigating infected wounds: 4 per cent.; gr. 8.75 two in 1 oz., or gr. 87.5 one in 5 oz. of water.

For use as a mouth wash: 1 per cent.; gr. 8.75 one in 2 oz., or gr. 87.5 one in 20 oz. of water.

For irrigating bladder and uterus in septic cases and for chronic urethral infection: 0.5 per cent.; gr. 8.75 one in 4 oz., or gr. 87.5 one in 20 oz. of water.

It will be seen by reference to p. 161 of the *JOURNAL* of January 29th that Dakin and his colleagues found that the germicidal action of chloramine, when tested against the ordinary organisms found in infected wounds, is about as powerful as an equal weight of sodium hypochlorite; as the molecular weight of chloramine is about four times that of sodium hypochlorite, the germicidal action of one molecule is about four times as great; as it is less irritating, it may be used safely at a concentration five to ten times as great; it is readily soluble in water and neither precipitates nor coagulates proteins such as blood serum. Its mode of action is thus summed up by its discoverers:

Chloramine represents an active antiseptic containing a store of chemically combined chlorine in a form which is quite stable and non-irritating under ordinary circumstances. But when brought in contact with proteins and similar cell constituents containing basic (NH_2) groups, it acts like a chlorinating agent, losing its chlorine to the basic substances, and thereby exerting its antiseptic action as needed. Chloramine, being a highly reactive substance, should not be mixed with other antiseptics; Both alcohol and hydrogen peroxide are decomposed by it.

The prices for the soloid preparations are unfortunately very high—72s. a dozen for the bottles containing 100 of 8.75 grains, and 54s. a dozen for tubes containing 10 of 87.5 grains. The manufacturers state that these prices are abnormal; owing to the use of chloramine bodies in the making of explosives, materials ordinarily obtained as by-products have now to be made.

MR. SAMUEL MATHER of Cleveland, Ohio, has founded a school for the graduate study of tuberculosis as a memorial to the late Dr. Edward L. Trudeau. The school will probably have its local habitation at Saranac Lake, New York, but co-operating agencies for special study will be created in New York City.

Correspondence.

THE PHYSICS OF A SURGICAL DRESSING.

SIR,—I was delighted to read Lieutenant-Colonel A. Primrose's paper on the above subject in your issue of February 12th, p. 238. For the last three weeks I have been making some simple experiments with water in a glass bottle and a wick leading out of it into a tray. Some methyl blue was placed on the wick at the neck of the bottle to show the direction of the flow. When a bell-jar was placed over the whole apparatus I found that the wick leading into the bottle became stained with the blue dye for nearly an inch, suggesting that under these conditions there was a tendency for the drainage to flow backwards.

My experiments are not yet nearly completed, but I fancy that there are three main conditions that affect the direction and the rate of flow:

1. The difference of level of the fluid in the bottle and the tray.
2. The relative dryness of the air in the bottle and over the tray.
3. The presence of salts in either the bottle or the tray—that is, the effects of osmosis.—I am, etc.,

Newcastle-upon-Tyne, Feb. 13th.

A. S. PERCIVAL.

SIR,—It was with very great pleasure that I read Lieutenant-Colonel Primrose's article under the above heading. Therein he calls attention to a very widespread fallacy in the after-treatment of infected wounds, and the experiments he quotes in support of his argument place on a scientific basis what has been obvious to me clinically for many years.

Whatever bacteriologists may say on the treatment of localized suppurative infections, our most successful treatment still consists in establishing free drainage, and maintaining it until the wound has healed. If this is done, I believe it matters little whether mild antiseptic solutions, salines, or plain sterilized dressings are subsequently applied, for once the tension is relieved the part is automatically flushed with serum and its contained antibacterial substances, whatever they may be.

Fomentations as usually applied consist of a piece of lint wrung out of hot boracic solution, and covered by a piece of gutta-percha tissue or oiled silk larger than the wet dressing, so that when applied it overlaps the latter all round. By this means evaporation is reduced to a minimum, bacteria and discharges are pent up beneath this impervious material, the wound and surrounding skin are left to "stew in their own infected juices," and free drainage no longer exists. In this way the chief object of an incision into an infected area is often neutralized. It has been my endeavour for several years past to impress this fact on the students and nurses of the Birmingham Medical School, but the use of "fomentations" is so firmly established by tradition and usage that it is difficult to eradicate a custom condoned by generations of surgeons.

My attention was first drawn to this matter by the frequently disastrous results which followed the treatment of whitlows in hospital practice. In such cases, despite early incision and free drainage (the routine after-treatment of which is the application of fomentations), in a few days the skin is macerated and undermined with pus, the edges of the wound everted, oedematous and unhealthy, and in a large percentage of cases this treatment fails to prevent the spread of infection up the finger to the palm. It seemed obvious to me that, although surgically free drainage had been established, there was something interfering with the free discharge of the infected fluids, and it did not require any great amount of discernment to fix the blame on the gutta-percha tissue.

For several years I have discarded impervious materials in the after-treatment of infected wounds, using as a rule only dry sterilized dressings, but if pain is severe and requires heat for its relief, or if the discharge is so thick that it will not soak into dry dressings, I use gauze wrung out of hot saline or some mildly antiseptic solution, and covered with several layers of hot dry wool. These do not retain the heat so long as the old-fashioned fomentations, but this is an advantage, in that it is an incentive to change

the dressings more frequently; once an hour is not too often for a freely discharging wound.

By these means the maceration and infection of the surrounding skin is prevented, the infection is rapidly localized, the wound takes on a healthy appearance, and free drainage, once established, is maintained.—I am, etc.,

Birmingham, Feb. 14th.

BERNARD J. WARD.

SIR,—The article by Lieutenant-Colonel Primrose, in your issue of February 12th, is really too absurd, and will, I am sure, raise a storm of protest. The experiments he quotes are of no value whatsoever in support of his statements. Does he not realize that the dressing must be kept moist by an impermeable material, so that drainage is established and maintained by capillary attraction? We are not dealing with flasks of water in surgical practice, but with tissues of more or less solidity. How often have we seen the evil effects—sometimes leading to general blood poisoning and death—which result from the application of dry dressings to septic wounds. Impermeable materials are only of use in keeping the dressing moist, so that capillary attraction is not interfered with; a piece of oiled silk applied directly to a septic wound is every bit as injurious as a dry dressing. I sincerely trust that this article will not cause any practitioner to depart from the old principle of using dry dressings for aseptic surgical wounds, and moist dressings covered with some form of impermeable material for all septic injuries. Otherwise it will be bad for him, and a good deal worse for the patient.—I am, etc.,

Wigan, Feb. 13th.

J. THOMSON SHIRLAW, M.D. Edin.

SIR,—Lieutenant-Colonel Primrose, in the article he contributes to the BRITISH MEDICAL JOURNAL of February 12th, comes to the following conclusion: "I am convinced it would be greatly to the advantage of the wounded if impermeable protective and oil-silk were entirely removed from the surgical armamentarium of the army." Colonel Primrose points out how impermeable tissue is commonly badly employed, just as others have found fault with the use of the probe, but it is absurd to suppress either if it be useful when properly handled.

Many men use a probe as a soldier should a bayonet! With such it is the method, not the means, which is at fault. Impermeable tissue should cover a wet dressing as a tarpaulin does a hayrick, not as it covers goods on a railway truck.

Colonel Primrose says: "In my opinion, the best dressing for septic wounds is a moist dressing, and we found the hypochlorous acid solution wonderfully effective. The moist dressing is applied directly to the wound, and over this dry gauze." Thus treated it would not remain a moist dressing for many hours, and either the wound would have to be dressed with exhausting frequency, or the dressing would be found dry and adherent when removed.

If a wound be discharging freely I cover it with a patty-pan, bent to shape, and having a large hole through its centre. All discharge can then easily escape. If a moist dressing be employed, a pad of wet wool should be put over the wet gauze to help keep it wet, and then a cap of impermeable tissue on top. If the impermeable material be scarcely larger than the dressing it covers, none of Colonel Primrose's troubles will arise, as all discharges can escape laterally. Moreover, a small piece of impermeable is economical, since less wool is required to cover it and extend the needful distance beyond.

Colonel Primrose gives evidence to show that an impermeable material over a dressing tends to urge any chemical constituent in the dressing inwards towards the skin or wound. Such an argument should encourage him to recommend it, since if the solution he prefers—that is, hypochlorous acid—be urged inwards so much the better for the wound.

In my experience a good treatment for discharging wounds is free drainage; a better is continuous irrigation; the best is baths. Dressings are chiefly put on for convenience, since a painful wound wants protecting, and so do the clothes or bed. Little can be done for a deep discharging wound beyond removing dead bone or foreign

bodies operatively, and keeping the parts clean, open, and quiet.

Most surface wounds heal excellently in practice with wet hypochlorous dressings capped, rather than covered, with waterproof tissue. There is, however, no absolute rule in medicine or surgery. I often dress the same wound in two or three different ways in a week. The more experience I have the more I disbelieve in "A" being always good and "B" being always bad, provided "C," the *chirurgien*, uses his wits.—I am, etc.,

Exeter, Feb. 12th.

D. W. SAMWAYS.

TRENCH FEVER.

SIR,—Captain J. W. McNée and his colleague, Lieutenant Arnold Renshaw,¹ are greatly to be congratulated on their demonstration that the causal organism of this disease is transmissible from man to man by blood injections. Their demonstration of this fact is indeed the fundamental basis for all future work on trench fever, especially for immunizing experiments, affording as it does an invaluable control, which is, unhappily, still wanting in many systemic infections of obscure etiology. The majority of the other conclusions drawn from their published experiments—such as that trench fever is a disease *sui generis*, that it is not transmissible by injections of moderate volumes of serum, and that the virus is mainly intracorporeal—appear to be well founded, and to be capable of ready confirmation.

The conclusion, however, that failure to prove infectivity of filtrates of saline extracts of crushed blood corpuscles is good evidence that the virus of trench fever is not filterable, and is therefore presumably of considerable size (though this is only inferred), is on a somewhat different footing, and for this reason. If it is desired to test the filterability of a virus, and hence to get some idea of size relatively to the vanishing point of vision, one condition must in some diseases be observed, even when working with the unsatisfactory Berkefeld filters, before it is possible to come to a final conclusion; and this condition is that the organism it is desired to test must be as far as possible isolated from the albuminous medium in which it occurs before filtration is attempted. And this applies equally to plasma, serum, haemoglobin-stained fluid, and to saline extracts of crushed blood corpuscles. If this isolation be not carried out it is often impossible to prevent blocking of the filter with colloidal albumen, which may be, and often is, fatal to the passage of certain types of small organisms. And this blocking is not necessarily prevented by mere dilution, even up to the limits of practical experiment. In my own work, for example, it has often happened to me—particularly in typhus fever, cerebro-spinal fever, and scarlet fever—to find that attempts to prove the infectivity of filtrates of the blood, serum, plasma, or other albuminous fluid may fail by using the classical technique recommended in the textbooks. And this even when working with high dilutions. If, however, the fluid suspected of harbouring a minute virus be well centrifuged, and if the whole of the albuminous medium—as far as is practicable—be replaced by saline the filtrate will now often prove to be infective, when before it proved to be non-infective. In the case of corpuscles suspected of harbouring a virus, freshly distilled sterile water will often give a far better extract for purposes of filtration than will crushing followed by treatment with saline, the tinted supernatant fluid, after centrifuging, being in the first case finally replaced by saline.

If therefore experiment fails to reveal the presence of a virus in a filtrate when the ordinary methods are adopted, some such method of isolation as that referred to should be given a trial before concluding that the virus is not filterable. The fact that no organisms could be seen in blood films rather suggests the presence in trench fever of a minute virus which may require special treatment before it can be proved to be filterable or the reverse. And it is well to remember that minute organisms are often more difficult to see in an albuminous than in a non-albuminous matrix.

If Captain McNée and Lieutenant Renshaw will accept the suggestion, they may perhaps find it worth while to repeat their filtration experiments on these lines. And if in addition they care to incubate the filtrate, after enrichment with sterile ascitic fluid or with serum-broth,

interesting cultural results may be obtained which are often unattainable when the ordinary methods of filtration of albuminous fluid containing an infective virus are employed, involving moreover the possible retention in the filtrate of antibodies.—I am, etc.,

London, W., Feb. 14th.

EDWARD C. HORT.

THE ETIOLOGY OF CEREBRO-SPINAL FEVER.

SIR,—I have not the necessary qualifications either to support or to question the very interesting speculation launched by Dr. Edward C. Hort¹ in your issue of January 29th, that the true infective agent of epidemic cerebro-spinal meningitis is a filter-passing organism, and that the meningococcus of Weichselbaum, incapable itself of reproducing the disease, is but a phase in the life-history of a more virulent ancestor.

In that article numerous specimens of the unfiltered body fluids are described as containing the following organisms when submitted to complete examination:

- (a) The meningococcus of Weichselbaum.
- (b) The meningobacillus.
- (c) Clusters of very minute organisms, sometimes diplococcal or diplobacillary in form, at other times of quite indeterminate morphology.
- (d) Jaeger's diplococcus.
- (e) Involution forms, diphtheroidal forms, and large bacillary forms.

Now, in so far as certain observations of mine² are cited, amongst others; as confirming these findings in their morphological details, may I say that the experiments in question, so far as I am able to judge, do not appear to have the significance attributed to them here?

From what appeared to me to be pure cultures of meningococci isolated from the cerebro-spinal fluid and from the blood of patients in the acute stage of the disease, there developed in subcultures Gram-negative and Gram-positive diphtheroids, bacilli, and diplococci. With a very definite and full reservation as to the possibility of contamination; I suggested that these results, if confirmed, indicated that the meningococcus was a pleomorphic organism. Again, if contamination could be excluded, these findings would indirectly support the thesis, based on other evidence, of some relationship between the meningococcus and an ultramicroscopic filter-passing organism. On the other hand, if it be a fact that the unfiltered body fluids in this disease contain at least five other varieties of micro-organisms, then my own results must be explained by the presence of these secondary organisms as contaminations in the earlier colonies of meningococci.

That seems to be a very possible and probable contingency, which I readily accept, but as a corollary it deprives my observations of any bearing whatever either on the question of pleomorphism or on the more speculative issue regarding the existence of an unknown virus.

More recent observations on changes in a culture of parameningococcus, isolated at the Royal Naval College, Greenwich, from the naso-pharynx of a contact, have increased my scepticism of pleomorphism, the existence of which must either be established or refuted by the final test of animal inoculation.

In conclusion, may I enter a plea, amidst the purely biological research now surrounding the disease, that "the truer and better means of prevention" should not be neglected? This last, when all is said, written, and done, shall be first. For one thing, the necessary measures have the simplicity of being eminently practical.³ Thus only last week a Brigadier-General wrote: "We had a lot of it (spotted fever) last winter. Yesterday I got my crowd together and talked to them for half an hour about this open air business . . ."

Whatever be the virus it can only exist, develop, and spread under those unhygienic conditions of warm, saturated, impure air too long tolerated by an ignorant civilization, in which unphysiological overcrowding is permitted and legal overcrowding is condemned.

It is clear that under all circumstances and conditions the intelligent recognition of a few simple measures based on physiological laws must inevitably imply that epidemic

¹ BRITISH MEDICAL JOURNAL 1915, i, p. 156.

² Practitioner, January, 1916, p. 17.

³ Lancet, 1915, ii, p. 862.

cerebro-spinal meningitis will cease to be. It is a sad commentary on so great a possibility that fresh cases of this disease are now appearing.—I am, etc.,

HALLIDAY SUTHERLAND,
Temporary Surgeon R.N.

February 1st.

SEGREGATION OF CONSUMPTIVE SOLDIERS AND OTHERS.

SIR,—At present the tuberculosis dispensaries register increasing numbers of broken soldiers and one hears on all hands of hospitals at home and abroad steadily accumulating cases of pulmonary tuberculosis.

Segregation camps—and the necessary legislation for placing the patients in them—will be urgently necessary, and the sooner the matter is taken in hand the better. With the completion of training of the new army it is reasonable to think that many camps suitable for the purpose will be available, and the necessity of putting up the proposed permanent buildings should not arise.

The problem of segregating the infective consumptives will have to be faced, and will tax all the administrative genius of our empire. Public opinion and the so-called freedom of the subject will have to be reckoned with, and will doubtless make the effectual control of this fell disease more difficult than that of stamping out leprosy in the middle ages. Some old churches exhibit to this day leper squint holes, and bear witness to the part the Church took in the crusade; if need be the religious organizations must be called in to our assistance once more if science and its ancillary legislation fail in the task.—I am, etc.,

J. LEWIS THOMAS,

Tuberculosis Officer for West Monmouth.

Newport (Mon.), Feb. 14th.

THE SOLDIER'S HEART.

SIR,—The letters which have appeared in your columns on the subject of "The Soldier's Heart" and the "Irritable Heart of Soldiers," have brought into prominence two points of practical importance, namely, that the condition under consideration is not peculiar to soldiers who have undergone the strain of modern warfare, and that it may be recognized before they proceed to active service. In respect of prompt recognition it would be difficult to improve on the suggestions of Dr. Stewart Allan Orr.¹

The syndrome in question has engaged my attention for many years, and was described by me in a communication to your issue of March 8th, 1913, as being one of cardiovascular atony characterized by mental depression, undue fatigue on exertion or mental concentration, cold and bluish extremities, dicrotic pulse with deficiency or absence of the predicrotic wave, respiratory variations of pulse frequency, postural tachycardia, functional murmurs, and frequently dilatation of the pupils, as well as precordial pain due to fibrositis of certain parts of the chest wall. At the same time I pointed out that the condition is one frequently met with in civil life, especially in children and adolescents, that it is dependent on toxæmia, and is especially liable to assume an acute form in soldiers under the strain of route marching and manœuvres, especially if combined with depressing climatic conditions.

As the suggestions as to treatment have, I think, been somewhat halting and inconclusive, and some have expressed themselves in a tone bordering on hopelessness, I wish to state, as the result of long experience, that a means of cure lies ready to hand. While digitalis and strychnine are of doubtful value, and calcium chloride and adrenalin hydrochloride (orally administered) are often useful as adjuvants, there is no remedy to be compared with the so-called Nauheim methods when administered in this country with judgement and due attention to technical details. As a rule the patient is restored to health, hopefulness, and activity in about two months, and able to resume an active and even arduous life with the keenness and confidence of full vigour. If the toxæmic condition have been successfully dealt with the result may be looked on as permanent.—I am, etc.,

London, W., Feb. 12th.

W. BEZLY THORNE.

THE NOTIFICATION OF MEASLES.

SIR,—You raise some interesting points in your last week's review of the position of practitioners under the new Notification of Measles Order. It will, I believe,

become evident as experience is gathered that the effort to limit the expense by barring practitioners from notifying—whether first cases, or cases in the same house wherein one case has been notified within two months—will defeat its own object. Every case notified by a parent or non-medical person must be a doubtful case not yet diagnosed until some medical person has come in to diagnose it. It cannot be necessary to point out the importance of a correct diagnosis being made in this connexion and the occasional difficulty which presents itself in diagnosis even for a much experienced medical practitioner.

The Local Government Board appear to expect the medical officer of health, or some person qualified to make a diagnosis who acts under the instructions of the medical officer of health, to visit the house to make the diagnosis when the notification is by a non-medical person. This will necessitate the case being examined, and then what about its treatment? Is the medical officer of health or his assistant (medically qualified or unqualified) going to take the onus of advising as to treatment? I do not see how he can do that, but I do see from the experience I already have that a good excuse has come into being for parents who desire to save the doctor's fee writing notes to the medical officer of health soliciting visits, and when they learn that the mention of measles enforces a visit their own diagnosis will probably run in this direction. Such visitation from the health department cannot be done without cost; in fact, it seems to me the cost will be greater than if a doctor's certificate were insisted on.

The one and only object, so far as I know, of the notification of measles is to prevent the death of children from the disease, and the one effective advice that I, and as I suppose all other medical officers of health, have been able to give to parents with children so suffering is to call a doctor in, as the disease is dangerous. But now if we are to save as many notification fees as possible we must keep the doctor out, and when we pay our somewhat costly visit (taxi-cabs are rather expensive), we must be sure to impress the parent to tell the doctor as soon as he comes that the medical officer of health has been in and diagnosed the case, and so prevent the payment of the additional half-crown. It has been seriously suggested to me that I should endeavour to forestall the doctor by sending out circular letters to parents living in poor streets where measles cases are known to exist, calling their attention in particular to their obligation to themselves notify any case arising.

But, after all, the medical officer of health will be the worst sufferer in this officially ordered notification of measles. Too little consideration has been given to his position, and the great responsibility thrown upon him, which I anticipate will become manifest from time to time in the coroner's court.—I am, etc.,

J. H. GARRETT, M.D., D.P.H.,

Medical Officer of Health, Cheltenham.

Cheltenham, Feb. 5th.

THE EDUCATION OF NURSES.

SIR,—No one will deny that nursing is a skilled profession or occupation. Does any other exist in which the worker is expected to start work without any preliminary training? The usual routine for the nurse entering as a probationer is to go straight into the wards and start nursing (?) at once. She picks up as much or as little knowledge as the staff nurse or sister has time or inclination to give. She attends a course of lectures, at the end of which she has certain information which she probably needed on the first day in the wards.

The training is given gratuitously, consequently the nurse has no right to complain. If she meets with the disapproval of the sister, there is the possibility that her conduct may be reported to the matron; she may be told she is unsuited for a nurse and her chance of training is at an end, for there is no court of appeal from the matron's word.

Now I hold that no one should be deprived of the right of taking up a course of training and carrying it through. How can any one say after a few months' training (if it is training a probationer gets) whether she is capable or not? Many medical students are slow in learning, and yet become capable at the end, and no one dismisses a student at the beginning of his course of instruction for incapability; why then a nurse? Again, persons qualifying for

¹ BRITISH MEDICAL JOURNAL, February 5th, p. 218.

a profession are usually taught by those chosen on account of special aptitude for imparting instruction. At hospital any staff nurse or sister is called upon to train the probationer regardless of her qualifications as a teacher. There is no systematized instruction in practical work. The lectures are often left to the house-surgeon, house-physician, or resident medical officer, who is chosen for the post with a view to his qualification as a doctor, and not as an instructor of nurses.

The remedy is to start nursing schools in connexion with the hospitals on the same lines as medical schools. In the first place, the training must be paid for, and secondly, the nurse must have an education in nursing. For the first six to twelve months the training should be theoretical, with demonstrations only; the nurse should not go into the wards at all, except for demonstrations. Then the next year or two ward work should be undertaken, still under supervision. The nursing school should also provide special opportunities for public health work, and make arrangements for its students to work at infant consultation centres and with health visitors and school nurses; also for the special branches of nursing—for example, midwifery, massage, electrical, and x-ray work.

The curriculum should be laid down and the examinations held by an outside body, who would be entitled to grant certificates (or even a diploma) for general nursing and special certificates for individual branches, particularly midwifery and public health.

A scheme as above outlined would safeguard the profession from a danger which is inevitable in the near future—namely, the flooding of the market with women calling themselves "nurses," whose only training has been a short residence in military hospitals. I have said nothing of the advantages accruing to the patients in hospital from such a scheme.—I am, etc.,

Brixton, Feb. 12th.

MILDRED M. BURGESS, M.D.Lond.

SCIENCE, EDUCATION, AND GOVERNMENT.

SIR,—My attention has been drawn to an article on "Science, Education, and Government" in your paper of February 5th. It is impossible to be otherwise than in sympathy with the writer in the purpose of his article, but I hope you will let me point out that the study of natural science is not neglected at the public schools. I have an intimate knowledge of the curricula of two well-known schools. At each of these science—both physics and chemistry—is taught to practically every boy on the modern side, at least four periods in the week being devoted to the subject in the lower sets, and six or seven periods in the higher sets. And at each of these schools not less than 60 per cent. of all boys are on the modern side.

Of the other branches of science mentioned in your article, biology is not generally taught in schools, and geology, which was formerly taught to many army candidates, has—so far as I know—unfortunately dropped out altogether; but the ascertained facts and principles of mechanics and geography are taught, and I think well taught, to modern side boys at all good schools known to me.—I am, etc.,

S. E. LONGLAND,

Glenalmond, Feb. 11th.

Warden of Glenalmond.

THE INTRODUCTION OF CINCHONA TREES INTO INDIA.

SIR,—Dr. F. T. Anderson of Horsmonden, Kent, has written to me, and I understand to you also, asking me to correct my attribution of "the whole credit" of the introduction of the quinine trees into India to Sir Clements Markham. Well, I was asked to write on Sir Clements's services in the matter for an obituary notice of him in your last issue [the 12th inst.], and having regard to the limits of space, and the even more pressing dictates of comparative relation, after a brief reference to previous efforts to naturalize these trees in India, I went on to describe in some detail the immediate and unique success of his importation of them from South America into Southern India, being careful to name all those, with one regretful and quite unintentional exception, who assisted him in this specific and crowning undertaking, the exception being Cross the gardener, who, after Sir Joseph Hooker and Sir George Clerk, Markham would have wished me to name; and I concluded with a brief reference to those who, after MacIvor

had so wonderfully propagated Markham's trees in the Nilgiris, helped to propagate them elsewhere, in Northern India. I regret that among them I did not mention Dr. Thomas Anderson, particularly as he was a contemporary with me and of mine own age at Edinburgh, where he graduated a year before me. But I was thinking, and deliberately, of Markham's own work in the connexion and under the emotion of his death. He was a thorough English gentleman, of the inborn historical type, developed to its highest mettle under the discipline of service in the Royal Navy; and to this, in simple truth, was entirely due his success in a great benevolent and beneficent adventure wherein there is really no second to stand beside him as first. Had I been writing for an encyclopaedia I certainly should have mentioned Dr. Thomas Anderson; and not only him, but Broughton and Falconer, and Fortune, and John Eliot Howard, and Kasten, and Nassau Lees, and De Vrij; and I hold that after Markham we owe most for the blessing of an exhaustless supply of quinine in India to Howard, the author of *The Quinology of the Indian Plantations*.—I am, etc.,

Baling, W., Feb. 15th.

GEORGE BIRDWOOD.

* * A printer's devil, of a hue blacker than usual, transposed the figures giving the age of Sir Clements Markham; he was born on July 20th, 1830; his age was thus 86, and not 68, as printed on p. 247.

LEGAL AND MORAL OBLIGATION.

SIR,—In this discussion I am under the disadvantage, from which you evidently do not suffer, of having at hand neither legal advice nor legal authorities; nevertheless, I stick to my point. I deny that I have confused moral with legal duties, and I contend again that the duty of a citizen to inform the authorities, when he has knowledge of the commission of a criminal offence, is a legal duty and not a moral duty. You say a legal duty is one to which the law will enforce obedience. I agree, provided the law is appealed to. And you say the duty which lies upon ordinary citizens to inform the authorities of a criminal offence is one to which no legal consequences attach. I speak under correction, but I submit that in this you are wrong. The same mistake—that no legal consequences attach to the neglect of duty—was recently made on the same ground, that the law is seldom put into operation, by a man who refused to assist in the arrest of a malefactor when called upon in the King's name by competent authority to do so. That man was indicted for his refusal, and was punished by legal process. Is it to be supposed that a man who could be proved privy to the recent crime of destroying the Government buildings at Ottawa could not be punished for concealing his knowledge? I am much mistaken if he would not be indictable under the common law, and if he would not find the crime of misprision of felony revived for his benefit; and even if this were not so, he could certainly be committed to prison for contempt of court if he refused, in the witness-box, to make the revelation.

You admit that barristers and solicitors are exempt from the duty if the knowledge comes to them from their professional relations with their clients; but you do not say, what is nevertheless the fact, that they are exempted by law. How can they be exempt by law if there is no law which would catch them if they were not exempt? Who brings in a bill of indemnity to absolve him from punishment that he has not incurred, and to which he is not liable? You declare that the duty of the priest to divulge the secrets of the confessional is a moral duty; but you do not venture to declare that the duty of the lawyer, from which he is exempted by law, would, but for this exemption, be a moral duty. Manifestly it would be a legal duty, and if it is a legal duty in his case it is equally a legal duty in the case of the priest and of the ordinary citizen who is neither.—I am, etc.,

Parkstone, Dorset, Feb. 12th.

CHAS. A. MERCIER.

* * A person who refuses to assist a police officer in arresting another who is about to commit a breach of the peace is guilty of a breach of a legal duty for which, as is well recognized, he is liable to be indicted. The question whether the law is habitually invoked in order to enforce any given duty has no bearing upon whether such duty is a legal or merely a moral one. The point is, Does the duty rest upon law or merely upon public opinion? If the

former, then it is a legal duty; if the latter, a moral duty and no more.

As was stated in the article on "The Duties of Medical Practitioners in Cases of Criminal Abortion," in the JOURNAL of February 5th and the note to our correspondent's previous letter which was published in last week's issue, there is no legal machinery by which the duty which rests upon ordinary citizens to give information to the authorities in cases where a criminal offence has been committed can be enforced. We therefore called such duty a moral one, and in this we have no doubt.

The position of barristers and solicitors to which our correspondent refers is this: Unlike any other class, barristers and solicitors are "privileged" in that they are not legally compellable—and, indeed, are not by law entitled—to divulge in the witness-box information which they have obtained from their clients. It therefore follows that the ordinary moral duty of the ordinary citizen to inform the authorities does not apply. But for the legal "privilege" which the barrister and solicitor enjoys in the witness-box, his position would be precisely similar to that of any one else. He might or might not be under a moral duty to inform the authorities.

The central fact, however, which emerges from this discussion, and which we wish once again to emphasize, is that it is now established that medical practitioners who obtain information in their professional capacity as to the commission of a criminal abortion are under no duty of any sort or kind to divulge that information to the authorities, and that their duty to their patients enjoins them to preserve professional confidence and secrecy.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on January 20th.

Clinical Clerks and Surgical Dressers during the War.—It was resolved to admit students who have performed service as clinical clerks or as surgical dressers for not less than six months during the continuance of the war, to the M.B., B.S. Examination after an interval of not less than two and a half years from the date of their passing the second examination for medical degrees in anatomy and physiology, provided that they be not admitted within five and a half years from the date of their matriculation.

Anatomical Nomenclature.—The examiners in anatomy were instructed that no change should be made in the existing nomenclature as used in examination papers without the sanction of the Senate.

The University Medal in Branch IV (Midwifery and Diseases of Women) of the M.D. Examination, December, 1915, has been awarded to Lillias M. Blackett, B.S. (London Royal Free Hospital School of Medicine for Women).

The Lindley Studentship of £100, offered every third year, and a University studentship in physiology, valued £50 for one year, are offered. Full particulars can be obtained from the Academic Registrar.

The Rogers Prize of £100, open to all persons whose names appear on the *Medical Register* of the United Kingdom, will be awarded for an essay or dissertation on "The Nature of Pyrexia and its Relation to Micro-organisms." Essays and dissertations addressed to the Vice-Chancellor must reach the university by 4 p.m. on April 29th.

UNIVERSITY OF ABERDEEN.

At the meeting of the University Court on February 8th the Senate was requested to draw up conditions of appointment and regulations relative to the lectureship in pathology with special reference to malignant diseases, recently instituted by Sir Alexander M'Robert. Colonel Scott Riddell, senior surgeon to the Royal Infirmary, was appointed general council assessor, in room of the late Dr. Westland.

UNIVERSITY OF GLASGOW.

At the meeting of the Glasgow University Court on February 10th the Principal, Sir Donald MacAlister, said that 110 women students and graduates at Queen Margaret College had been training to take certificates under the St. Andrew Ambulance Association, in order to act as part-time nurses at hospitals so as to relieve fully trained nurses on military service. A register of women students and graduates, formed to discover reserves of educated women prepared to take on the work of educated men training for military service, showed that 407 out of 438 students had registered themselves. The students and graduates of the university working on munitions numbered 423, and of that number 300 were engaged for the period of the war, many being either unfit for military service or exempted by reason of special circumstances.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary council was held on February 10th, when Sir William Watson Cheyne, president, was in the chair.

A vote of condolence was passed to the relatives of the late Mr. Stanley Boyd, a member of the council.

Diplomas were granted, jointly with the College of Physicians, to four candidates found qualified for the diploma in public health at the recent examinations.

Mr. C. H. Golding-Bird was re-elected to represent the college on the Central Midwives Board.

CONJOINT BOARD IN ENGLAND.

The diplomas of L.R.C.P. and M.R.C.S. have been conferred upon the following candidates:

J. Andrew, *Mary N. Andrews, G. F. V. Anson, K. J. Bates, T. A. P. Benbow, A. W. C. Bennett, K. H. Bhat, J. T. Bleasdel, E. S. Bowes, *Isabel F. Buckle, A. O. Courtis, D. Crellin, R. G. Dani, P. A. Dargan, L. M. Davies, L. ap I. Davies, H. M. Drake, A. N. Drury, C. Y. Eccles, M. Elias, H. H. Elliot, C. A. L. Evans, D. J. Evans, M. D. Evans, W. J. Evans, C. Gould, H. E. Griffiths, A. B. Gunasekara, C. G. W. Hahr, A. E. Hamlin, W. L. A. Harrison, G. E. Heath, V. R. Hirsch, E. L. Hopkins, *Helen Ingleby, V. C. James, J. G. Jones, L. W. Jones, *Ivy Keess, C. E. Kindersley, M. E. A. Latif, H. Lewis, K. T. Limbery, G. A. S. Madgwick, R. H. Mainot, L. A. Malik, F. W. Maunsell, *Gladys M. Miall Smith, R. D. Moyle, N. R. Nalliah, H. M. Oddy, *May Olivera, *Edith W. Paul, P. R. O'R. Phillips, A. C. Pickett, D. S. Pracy, D. Rees, E. D. Richardson, M. K. Robertson, G. C. Robinson, J. T. Samuel, F. J. P. Saunders, R. J. Scarr, C. P. Sells, G. B. Sellwood, *Edith A. Shaw, *Elsie Stansfeld, A. Sunderland, G. T. Symons, H. J. H. Symons, A. H. Taymour, W. H. Thomas, J. A. Tippet, R. S. Topham, H. M. von Mengershausen, H. J. Wallace, H. A. Whyte-Venables, H. G. E. Williams, A. Wilson, G. C. N. Younger.

* Under the Medical Act, 1876.

The Services.

EXCHANGE DESIRED.

MEDICAL OFFICER attached to Squadron of Royal Engineers wishes to exchange with medical officer holding hospital appointment in England or France—Address No. 750, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Obituary.

DR. GEORGE KIRKWOOD died at his residence in Peterborough on January 30th, after a long illness. He was the son of Mr. James Kirkwood, of Dunbar, where he was born in 1852. He was educated in that town and afterwards at the university and the College of Surgeons, Edinburgh. As resident medical officer at the Royal Infirmary he enjoyed the advantage of witnessing the establishment of antiseptic surgery under Lister. He afterwards held the appointment of house-surgeon to the Cumberland Infirmary, Carlisle, and before settling in practice was clinical assistant in the eye wards in the Edinburgh Infirmary. In 1876 Dr. Kirkwood joined Dr. Walker, sen., and Dr. T. J. Walker in Peterborough, and in the following year entered into a partnership with Dr. T. J. Walker which lasted for forty years. He became surgeon to the Peterborough Infirmary, and throughout his long professional career threw his whole heart into his work, more especially attending to the ophthalmic department. Dr. Kirkwood's services to the institution were recognized by a resolution passed, within a few hours of his death, at the hundredth annual meeting of the governors. He was a member of the British Medical Association, and had held the office of President of the Cambridgeshire and Huntingdonshire Branch. Dr. Kirkwood was dextrous as an engineer, a good photographer, and an accomplished pianist, and played on the French horn. He was most liberal in assisting all enterprises, especially musical societies, in which he took part. The funeral, which took place on February 4th, was very largely attended.

We are indebted to Dr. John Craig for the following notes of the life of Dr. MIDDLETON, who passed away at his residence, 152, Bruntsfield Place, Edinburgh, on February 7th. Robert William Middleton was born at Symington, Lanarkshire, on May 13th, 1853. For a short time he attended school at the neighbouring town of Biggar, and on his parents' removal to Thornhill, Dumfriesshire, continued his school career at Closeburn and at Dumfries Academy. He thereafter studied medicine at Glasgow University, where he received the degrees of M.B., C.M. in 1878. After acting as assistant to the late Dr. John Kello, of Biggar, he spent nine months in Paris

in post-graduate work. In 1888 he settled in London, where he gained a large practice. In 1892 his health gave way, and he was reluctantly compelled to give up work. After spending some time in endeavouring to recover his health at Southsea and at Reigate, he went to reside in Edinburgh about fifteen years ago, and had since been confined to the house and almost entirely to his bed. He was unmarried. Dr. Middleton was beloved by all who knew him. In his retirement he drew around him a small circle of friends who delighted to visit him. His keen appreciation of a good story and his hearty laugh will long be remembered by those who knew him. He was patient during his long illness, and although at frequent intervals he suffered great pain he never complained. On February 10th he was laid to rest beside his parents and grandparents in the quiet churchyard of his native village of Symington under the shadow of the hills he loved so well.

SURGEON-MAJOR-GENERAL JOHN PINKERTON, I.M.S.(ret.), M.D., who died on February 11th, at the age of 83, took the qualifications of M.D.Glas. and L.R.C.S.Edin. in 1855, and became F.R.C.S.Edin. in 1907. He entered the Indian Medical Service in 1855, and served in the Persian war, 1856-7. During thirty-eight years' service in India he held many important posts. From 1868 to 1876 he was superintendent-general of the vaccination department of the Bombay Presidency, and drafted the first Vaccination Bill in India, which became law in 1877. He was in charge of the European General Hospital, Bombay, from 1876 till 1882. He was the first president of the Bombay Branch of the British Medical Association, and had twice held the post of Dean of the Medical Faculty of the University of Bombay, of which university he had been a Fellow since 1868. He was honorary physician to Queen Victoria, and continued as such to King Edward VII and King George V. For five years preceding his retirement he was at the head of the I.M.S. in the Bombay Presidency. At the time of his retirement, in 1893, he was a member of the Legislative Council of the Bombay Presidency. He was the recipient of the good service pension of £100 for meritorious services. In 1894 he was elected F.R.F.P.S.Glas. for distinction in medical science. General Pinkerton lost his only son, Dr. John Pinkerton, in the Russo-Turkish war of 1878. He is survived by an only daughter, the wife of Dr. Ebenezer Duncan, president of the Royal Faculty of Physicians and Surgeons, Glasgow. The funeral took place at Cathcart Cemetery on February 15th.

COLONEL CHARLES FREDERICK POLLOCK, R.A.M.C.(ret.), died at Cowhenth, Dumfries, on December 19th, 1915, aged 71. He was born on December 24th, 1844, educated at Trinity College, Dublin, where he took the M.B. and M.Ch. in 1867, and entered the army as assistant surgeon on October 1st, 1867. He became surgeon on March 1st, 1873, surgeon-major on October 1st, 1879, attained the rank of colonel on August 3rd, 1898, and retired on September 7th, 1898. He served in the Egyptian war of 1882, was present at the battle of Tel-el-Kebir, and received the medal with the Khedive's bronze star.

BRIGADE SURGEON JOHN NORMAN DAVIS, R.A.M.C.(ret.), died at Clondarragh, Foxrock, co. Dublin, on December 30th, 1915, aged 77. He was born on October 15th, 1838, the son of the late James Davis, of Millbrook House, Galway, educated at Queen's College, Galway, and took the M.R.C.S. on July 30th, 1862, the M.D. of Queen's University, Ireland, on October 16th, 1862. Entering the army as staff assistant surgeon on April 14th, 1863, he became surgeon on March 1st, 1873, surgeon-major on March 18th, 1877, and retired with a step of honorary rank on April 18th, 1885. The *Army List* assigns him no war service. A great part of his service was spent in India. Since his retirement he had lived for twenty-six years at Clondarragh. He had been a member of the British Medical Association since 1880.

THE LATE MR. STANLEY BOYD.—Lieutenant S. G. Vinter, R.A.M.C., calls attention to Mr. Stanley Boyd's work as a member of the council of Epsom College. He took a keen interest in the success of the school, and did much to raise it to the high position it now holds.

Medical News.

M. GODART, Under Secretary (Health) in the French War Ministry, has addressed a letter to the Wounded Allies Relief Committee, thanking it for the valuable work it has done for wounded French soldiers, especially in maintaining hospitals at Limoges and Dieppe.

A COMMITTEE, with Viscount Hambleden as chairman and Captain H. S. Tunnard as secretary, has been formed to erect a memorial in the chapel of King's College Hospital to Miss Katharine Monk, who was for twenty-one years sister-matron of the hospital.

La Nipologia (we presume from *νήπιος*, an infant) is the title of a new Italian quarterly review devoted to the scientific study of childhood, with special reference to the hygiene and medicine of early infancy. The editor is Professor Ernesto Cacace of the University of Naples.

STATISTICS published in German journals show that, as might be expected, there has been a great falling off in the number of foreign students in the universities of Germany owing to the war. Whereas the number in the second semester of 1914 was 4,750, that for the corresponding period of 1915 was 1,305.

THE next course of lectures and discussions arranged by the Child Study Society, London, will begin at 90, Buckingham Palace Road, S.W., on Thursday next at 6 p.m., when Mr. Cyril Burt, psychologist to the London County Council, will speak on psychological problems arising out of the war.

AT the meeting of the Harveian Society of London on Thursday next, at the Stafford Rooms, Titchborne Street, Edgware Road, at 8.30 p.m., a discussion on the treatment of gunshot wounds will be opened by Sir Berkeley Moynihan, and continued by Mr. d'Arcy Power, Mr. Burghard, Mr. Percy Sargent, Mr. Clayton-Green, Dr. Fleming, and others. All members of the profession who may be desirous of hearing the discussion are invited to be present.

THE propaganda of the Pure Food Society is in abeyance during the war, but the National Milk Hostels Committee is doing excellent work, we are informed, in providing poor war mothers with pure milk under the certificate of the society. Medical men and their wives who desire to join the society should apply to the honorary secretary at 67, Jermyn Street, London, S.W.

THE nature and scope of the *Athenaeum Subject Index to Periodicals* were described in a note which appeared in the BRITISH MEDICAL JOURNAL of November 27th, 1915 (p. 799). The first two of the series of class lists, which are later to be incorporated into the annual index for 1915, have appeared. One of these, containing forty-eight pages, relates to the economic, political, and military history of the war, and was issued in January. The other, containing eighty pages, deals with science and technology with special reference to the war. The index, which is issued at the request of the Council of the Library Association, is published by the *Athenaeum*, Bream's Buildings, Chancery Lane, W.C.

A STIRRING appeal for funds on behalf of the French Red Cross has been written by Mr. Dion Calthrop in France. It is entitled *The Wounded French Soldier*, and contains a number of little pictures of French life as it has been transformed, tortured, and ennobled by the war. It is illustrated by a number of photographs showing the ruin of war in all its phases. Mr. Calthrop is a sentimentalist, quick to feel for the sufferer, quick to recognize the virtue of the armour of laughter and firm fortitude with which the French nation has armed itself in the desperate stress of modern warfare. The book, which costs 1s. 6d., should be widely read; the French Red Cross can and does make good use of every penny it receives, and its address is 9, Knightsbridge, London, S.W.

VOL. XV of the clinical series of the *Archives of the Middlesex Hospital* (London, Macmillan and Co.) contains the statistics of the patients treated in the various in-patient departments for the year 1913. In addition, it has an account of a case of systemic haemolysis with haemoglobinuria in a rheumatic woman of 56, by Drs. Pasteur and Whittingham; no note is made as to the presence or absence of Wassermann's reaction. Dr. Ward contributes a paper on the use of the electrocardiograph in the study of the heart muscle, with illustrative electrocardiograms. Brief notes on a few unusual or particularly interesting cases are appended to the report by the pathologist. The volume would, perhaps, gain by the inclusion of a table of its contents.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the **BRITISH MEDICAL ASSOCIATION** and **JOURNAL** are: (1) **EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology, Westrand, London*; telephone, 2631, Gerrard. (2) **FINANCIAL SECRETARY** AND **BUSINESS MANAGER** (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) **MEDICAL SECRETARY**, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the **British Medical Association** is 16, South Frederick Street, Dublin.

Queries answers, and communications relating to subjects to which special departments of the **BRITISH MEDICAL JOURNAL** are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

F. has in the past paid income tax on a return arrived at after deducting wear and tear of his car, but for 1915-16 the surveyor of taxes has objected. He inquires whether he is entitled to deduct depreciation, and if not whether he can claim an adjustment of his assessment for 1914-15 in view of the fact that in the year 1913—the last of the average for 1914-15 the cost of renewal of the car exceeded the sum deducted as depreciation.

The surveyor appears to be right, that is, the depreciation allowance does not apply to assessments on professions, and therefore the cost of replacement of a practitioner's car can only be dealt with as an expense as and when it is incurred. Presuming that our correspondent had proper notice of the assessment for 1914-15, he is not now entitled to any adjustment. At the same time, we may perhaps point out that he is still entitled to bring the cost into the average for 1915-16 and 1916-17, so that he has lost only one-third of the net cost of replacement, and against that he had the deduction which he made for depreciation for 1914-15.

C. W. S. left South Africa for this country on October 28th last. He inquires as to when he became liable to income tax.

It is necessary to distinguish between income arising in this country and income arising abroad. As regards the former, "C. W. S." becomes liable at once—that is, immediately such income is receivable; but as regards the latter, the liability is subject to the conditions laid down in Sec. 39 of the **Income Tax Act of 1842**—namely, that if he has come to this country for some temporary purpose only, he does not become liable if his stay here does not exceed six months.

THE CHANNEL ISLANDS.

B., who has practised in South Africa, and thinks of settling in the Channel Islands, asks for particulars as to general conditions and those specially affecting medical men.

* * We are indebted to **Dr. H. D. Bishop**, Secretary of the Channel Islands Division of the **British Medical Association**, for the following information: Any doctor whose name appears in the current number of the *Medical Register*, and who produces his certificate of registration (not diplomas, etc.) can be admitted to practise by the Royal Court upon paying a fee of £2 10s. A knowledge of French is not necessary, but it is useful in the country districts where the local patois is still spoken, although nearly every one understands English except a few of the old people. Local dialects are very different from ordinary French, and indeed they vary in different islands, and even parishes. The cost of living is much about the same as it is in England. The system of taxation is now being changed, and I cannot say what it will be in the future. Hitherto it has been a tax upon capital and real property, not upon incomes. At present any one could live here for two years without paying any local taxation, but that is going to be altered at once, which is not to be wondered at. People living here have to pay English income tax on investments other than those in the islands. Laws and customs differ in many ways in Jersey and Guernsey, and both have separate governments. No stranger should purchase any property in either island without first consulting a good lawyer, or he may find an apparently straightforward title a valueless one. A wife has certain extraordinary rights upon her husband's property, known locally as her "dower."

DEFORMITY OF THE EXTERNAL EAR.

D. J. G. W. inquires whether any good is likely to follow surgical interference in the case of an infant born with a deformed pinna of the ear, which is folded up and closed over

the meatus; no meatus can be felt. In such a case, is there a drum and meatus present?

* * From the literature on the subject it appears that in no case out of sixteen autopsies, on presumably similar cases, was the middle ear normal or a tympanic membrane found. It further appears that embryological, pathological, and clinical observations prove surgical interference to be useless.

LETTERS, NOTES, ETC.

THE COUNTESS OF CHINCHON.

It will be noticed that in his note last week **Sir George Birdwood** used the spelling "chinchona." He did so because the name of the countess after whom the genus was named was spelt Chinchon. The official spelling in the *British Pharmacopoeia* is "cinchona," and **Sir George** admits that in all English books the name of the plant is still spelt cinchona. "The right spelling," he characteristically adds, "is every where the wrong spelling of the majority, and wrong the right of the minority."

SEVERE TETANUS SUCCESSFULLY TREATED BY ANTITOXIN.
DR. JAMES ADAM (Hamilton) writes: Captain T. P. Kilner's report (January 8th, p. 46) of a case of recovery from tetanus developing five days after infection and his quotation from the **BRITISH MEDICAL JOURNAL** report that "if the disease has an incubation period of less than twelve days it is fatal in spite of treatment, whether by antitoxin or other means," recall a note I published in the **JOURNAL** of November 10th, 1906, of two cases of tetanus. In one the incubation period was ten days, in the other three days; both recovered.

The summary of the first case was: "Numerous dirty wounds; first symptoms on tenth day; first injection of serum on eleventh, last on twenty-second, two abdominal; total, 157 c.cm." The summary of the second case was: "Slight bruise of great toe; first symptom of tetanus by third day; muscles of jaw and spine chiefly involved. First injection of serum on seventh day (subdural), the last on the fourteenth; total, 100 c.cm. Wound swabbed with pure carbolic acid on seventh; required no more dressing."

These and Captain Kilner's case prove that the contention of the **BRITISH MEDICAL JOURNAL** report is incorrect and support his plea for perseverance in treatment.

* * The quotation in Captain Kilner's communication was taken from a report on the 2nd Eastern General Hospital, Brighton, published in the **BRITISH MEDICAL JOURNAL** of December 5th, 1914, p. 992.

THE DAILY FOOD RATION OF GREAT BRITAIN.

DR. J. C. MCWALTER (Dublin) writes: Adverting to Professor Thompson's very interesting food figures, published in your issue of February 12th, 1916, p. 239, it surely is a shocking thing to see the Government limiting the supply and raising the price of such invaluable articles of child feeding as sugar and fruit. Unnecessary luxuries are conveyed across the sea to minister to indolence and vice, whilst the scantily-fed child is robbed of the fruit which kept away scurvy, and of the sugar so vital to its growth. And, again, are all our university chemical laboratories incapable of turning out a few hundred pounds of phenacetin or phenazone, or even of sodium salicylate? It is painful to see sick men and women deprived of analgesic drugs, which have almost become a necessity, owing to their high price.

ANDREAS VESALIUS.

BIOGRAPHER writes: We must all agree with your correspondent, "J. E. (Edinburgh)," in his observation at the end of his paragraph on "The Angulus Ludovici" (**JOURNAL**, February 12th, 1916), that the student should know something of the men whose names are embedded in anatomy. Let it be remembered, however, that there is considerable difficulty in authenticating their names. Roth of Bâle, in his important biographical work, *Andreas Vesalius Bruxellensis*, published in 1892, shows that Vesalius's family name was not Wessels. "The family of Vesalius was originally called Witing, and was once domiciled in Wesel, in the circle of Cleves; later on it settled in Nymwegen and, in reference to its former home, changed its name into Wesalius. The three weasels (Dlemish *wesel*) on Vesalius's coat of arms are a play of words on its origin" (p. 38).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	...	0	5 0
Each additional line	...	0	0 8
A whole column	...	3	10 0

All remittances by Post Office Orders must be made payable to the **British Medical Association** at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

THE EPIDEMIC JAUNDICE OF CAMPAIGNS.

BY WILLIAM HENRY WILLCOX, M.D.,
F.R.C.P. LOND.,

LIEUTENANT-COLONEL, R.A.M.C.; CONSULTING PHYSICIAN TO THE
MEDITERRANEAN EXPEDITIONARY FORCE; PHYSICIAN TO
OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON.

THE following paper is based upon the study of a considerable number of cases of jaundice in the Mediterranean area during the past six months, and also on the study of a number of cases of jaundice from the Expeditionary Force in France during the earlier part of the war.

Jaundice is of common occurrence amongst troops on campaign. In the South African war a considerable number of cases were reported. In the present war jaundice has occurred amongst our troops in almost all parts of the sphere of operations.

The cases of jaundice of the epidemic type have fortunately been of a mild nature generally, and very few deaths have been reported. A considerable amount of incapacity for duty has, however, resulted, so that epidemic jaundice is a disease of importance from the military point of view.

The epidemic jaundice of campaigns is of great pathological interest, since it throws considerable light on the pathology of jaundice generally.

It will be convenient to consider, first, the symptoms of the common type of epidemic jaundice as seen in the Mediterranean area during the later half of the past year. Other varieties of jaundice which were also observed will then be considered, and the relation between them will be discussed.

SYMPTOMS OF EPIDEMIC JAUNDICE (THE COMMON TYPE).

The patient had usually some abdominal discomfort for a few days, associated with anorexia, nausea, and either diarrhoea or constipation.

Pyrexia, generally of a mild type, would then set in, and this was associated with some chilliness, and in some cases by an actual rigor. Vomiting occurred sometimes at this stage, and also headache. Sometimes there were "pains all over." Abdominal discomfort in the hepatic and epigastric regions usually occurred. The pyrexial period in some cases lasted only one or two days. Generally it was from two to four days, but cases have been observed in which it lasted as long as eight days.

Liver: Gall Bladder.

Jaundice now occurred, at first slight, but it gradually increased in intensity and became of the ordinary type of obstructive jaundice. The stools were pale and the urine bile-coloured when the jaundice became marked. With the onset of jaundice the temperature usually fell to normal and remained so.

At this stage definite enlargement of the liver could be made out. It was felt usually extending to one or two inches, or even more, below the subcostal border in the right nipple line.

The surface was smooth and the enlargement uniform. There was slight tenderness on palpation over the liver. It moved freely with respiration. In some cases there was definite enlargement over the gall bladder region, and on palpation the gall bladder could be felt. This enlargement of the gall bladder occurred in about 10 per cent. of the cases, and it no doubt indicated an obstruction due to the catarrhal inflammation of the duodenum, involving the common bile duct and its ampullary orifice into the duodenum.

The stools were pale when the jaundice was marked, and unless aperients were given they were constipated.

Spleen.

At this stage the spleen could usually be felt, extending for half an inch, or considerably more, below the left subcostal border on inspiration. In some cases there was definite tenderness on palpation over the spleen. Percussion over the splenic area showed an increase of dullness upwards. The tongue was often moist and clean, but in some cases it was moist and somewhat furred.

Circulation.

The pulse was quickened during the pyrexial period to, for example, 80 to 90 per minute, but with the onset of jaundice it became slow, in some cases being only about 50 per minute.

The heart condition was very interesting. A definite increase of the deep cardiac dullness occurred. This was most marked on the right side. On percussion in the fourth space to the right of the sternum the cardiac dullness extended often to two inches beyond the right sternal margin. The cardiac dullness showed only slight increase to the left, reaching to the left nipple line or half an inch or so beyond.

The dilatation of the right side of the heart in epidemic jaundice is very characteristic, and, apart from pulmonary conditions, the only other acute disease showing commonly a specific dilatation of the right side of the heart is acute rheumatism. Usually no cardiac murmurs were present on auscultation, though occasionally a systolic murmur would be heard with the first sound. The dilatation of the right side of the heart subsided with rest, but it usually persisted for several days.

Urine.

The urine showed the usual signs of a specimen from a case of obstructive jaundice. It was acid and contained bile pigments. Acetone and diacetic acid were not present in the cases examined. Albumin was absent, except in the exceptional severe cases. Casts were usually absent, except in very severe cases.

General Symptoms.

No anaemia was noticed in the cases observed, showing that this type of epidemic jaundice was not associated with haemolysis.

Pruritus was not a marked symptom in the cases of epidemic jaundice, though the jaundice was often quite deep for two or three weeks or more. Purpura occurred in a few of the cases. The cutaneous manifestations, such as lichen, urticaria, boils, xanthoma, telangiectasis, etc., which are common in cases of protracted obstructive jaundice due to other causes, were not observed here.

It is remarkable in cases of jaundice due to mechanical obstruction of the duct, without liver involvement, for what a long time the deep jaundice will persist without toxic symptoms due to bile absorption (cholaemia) developing.

In the cases of epidemic jaundice the toxic symptoms which occurred must be regarded as due either to the toxæmia of the infection, or to autointoxication from resulting degenerative changes in the liver, and not to the toxic effect *per se* of the bile in the blood.

Nervous System.

Asthenia was a marked symptom in all but the very mild cases of epidemic jaundice, and depression was a characteristic symptom in most of the cases while the jaundice persisted. It must be mentioned, however, that several officers remained on active duty throughout the whole period of their attack, and it was remarkable to see them doing responsible and important work while deeply jaundiced.

The reflexes (knee-jerks, plantar, and abdominal) showed usually no change, and signs of organic disease of the nervous system were usually absent.

In another paper I have called attention¹ to the frequency of the occurrence of epidemic jaundice amongst the few beri-beri cases occurring amongst the troops in the Dardanelles area. The beri-beri cases all showed marked signs of multiple neuritis, and it is possible that in some of the cases the toxæmia associated with a previous attack of jaundice may have been a factor in the development of beri-beri.

Epidemic jaundice was, however, not the sole etiological factor in these cases; there was a more important dietetic factor, to which was added a toxic factor associated with jaundice.

The marked general weakness which usually occurred in the cases of epidemic jaundice rendered convalescence slow. This was especially evident in the cases showing cardiac dilatation and marked hepatic and splenic enlargement. In these cases weakness and dyspnoea on exertion

occurred for some weeks, and the diminution in the size of the liver and spleen was slow.

Usually in the moderately severe cases of epidemic jaundice two months, or even more, would elapse before the patient was fit to return to active duty. In the milder cases the period of inability for duty might be less, but it was usually about two months.

Secondary Pyrexia.

Some of the moderately severe cases of epidemic jaundice showed a second period of pyrexia occurring after the temperature had become normal. This was exceptional unless the patient had contracted some other infection—for example, paratyphoid fever—in addition to the epidemic jaundice.

Toxaemia.

In very rare instances cases of epidemic jaundice showed symptoms of marked toxaemia after the development of the jaundice. Stupor and a low delirium and vomiting, sometimes associated with hiccup, occurred. The pulse became feeble and usually quickened in rate. Some collapse occurred, the temperature being usually subnormal. Coma supervened and death occurred.

The above symptoms of the gravest cases were similar to those associated with acute yellow atrophy of the liver. They resulted, no doubt, from the degenerative changes in the liver cells, caused by the toxins of the infective agent, and the final symptoms were mainly due to an auto-intoxication from defective liver function. Fortunately only two out of a large number of cases examined were of this grave type, terminating fatally.

OTHER TYPES OF JAUNDICE.

Other types of jaundice commonly met with were:

1. *Catarrhal Jaundice.*

In this type of case the patient had for a few days symptoms of anorexia, nausea, sometimes vomiting, epigastric discomfort, and general malaise. Pyrexia was generally absent. Jaundice occurred of the obstructive type, associated with pale stools, and bile in the urine. The liver was slightly enlarged, but the spleen could not usually be felt.

In these cases the general symptoms were slight, except that depression and general weakness were marked, and it was usually several weeks before the patient was fit for duty.

2. *Jaundice associated with Specific Infections.*

Patients suffering from such diseases as typhoid fever, paratyphoid fever, relapsing fever, dysentery, malaria, etc., sometimes developed jaundice in the course of them.

With typhoid and paratyphoid fever the occurrence of jaundice of a catarrhal type was not uncommon. The jaundice generally occurred about the second or third week of the disease, and it was not a grave complication, unless associated with acute cholecystitis, when in a few cases operative treatment was necessitated.

Dysentery, both amoebic and bacillary, was sometimes associated with jaundice of a catarrhal type in the course of the attack. This was no doubt due to secondary infection of the bile duct and bile capillaries. The dysentery cases showed a great susceptibility to secondary infections of various kinds. Thus in amoebic dysentery secondary paratyphoid infections were not at all uncommon.

In *relapsing fever* jaundice was observed in a number of cases. The jaundice was not of the type of the epidemic jaundice described above, but was usually of a slight intensity, occurring after the second or third day of pyrexia, and it was of the haemolytic and not of the obstructive type. Pale stools did not occur, and bile in the urine was not constant. This jaundice rapidly cleared up when the fever subsided, and it was often so slight as to escape notice, unless specially looked for.

In *malaria* slight jaundice of the haemolytic type and accompanied by definite anaemia was seen in chronic cases. Occasionally jaundice of the catarrhal type occurred in association with a malarial attack.

Mediterranean Yellow Fever.

Fortunately no cases of this type have occurred in the Mediterranean Expeditionary Forces, as far as I am aware.

Mediterranean yellow fever sometimes occurs in the Mediterranean area; it has been carefully studied by Dr. Ruffer, who has seen many cases and to whom I am indebted for a description of the disease.

It is a disease of high mortality. It begins with an acute onset, chilliness or rigor, headache, severe pains in the back and limbs, and high temperature being marked. Vomiting is common. The face is flushed and the eyelids are injected. Slight jaundice may occur during the first two or three days. Albuminuria is common and sometimes casts are present. In severe cases suppression of urine and fatal uraemia may supervene.

The temperature in a case of moderate severity will remain up for three or four days and then subside for a day or so, after which it rises again. In this secondary pyrexial period the jaundice becomes marked, haemorrhages such as haematemesis or melaena may occur, and frequently a profound toxaemia, like that of acute yellow atrophy, results, and death occurs. Mediterranean yellow fever resembles closely ordinary yellow fever, and it is probable that the infection is conveyed by the mosquito *Stegomyia fasciata*.

PATHOLOGY AND DIAGNOSIS.

Every case of jaundice seen on campaign should be examined with an open mind, and one should aim at making a true pathological diagnosis of the type of jaundice present. It is only by this means that prophylaxis and treatment can be carried out on correct lines.

It will be convenient briefly to review the causes of jaundice, and to consider the relationship of the "epidemic jaundice of campaigns" to other types of jaundice.

CLASSIFICATION OF JAUNDICE CASES.

These can be conveniently divided into two main groups:

1. *Obstructive jaundice*, where there is a mechanical obstruction in the common bile duct, preventing the flow of bile into the intestine. Types of this are:

1. Congenital absence of the bile duct.
2. Stricture of duct.
3. Obstruction in the duct itself:
 - (a) From foreign bodies—for example, gall stones, bile sand, or parasites;
 - (b) From growth in the wall of the duct;
 - (c) From swelling of the mucous membrane of the duct or its ampullary opening—for example, catarrhal jaundice.
4. Pressure on the duct from without—for example, tumours of pancreas, liver, stomach, etc., enlarged glands in portal fissure, aneurysm, etc., or kinking of the duct from dragging on it, as may occur in movable kidney.

2. *Non-obstructive Jaundice*.—This type has been called haematogenous jaundice, owing to the idea that the symptoms were the result of excessive bile formation consequent on increased blood destruction.

Modern research has shown that the distinction between the two types of jaundice is to some extent an artificial one. In most cases of non-obstructive jaundice, although no gross obstruction exists in the common bile duct or main hepatic ducts, yet there is an obstruction in the smaller bile ducts due to catarrh (cholangitis). Also in these cases the bile is altered in character, and often the viscosity is much increased. In many varieties of this type of jaundice there is increased destruction of red blood corpuscles and increased bile formation.

Hepatogenous Jaundice.

The terms "hepatogenous," "haemohepatogenous," and "intrahepatic" have been suggested for this type of jaundice—that is, for the non-obstructive type.

The following are its chief varieties:

1. *Toxic*, caused by chemical poisons. These may act by causing a cholangitis, and degenerative changes in the liver cells—for example, tetrachlorethane, chloroform, etc.—or by causing in addition marked haemolysis—for example, phosphorus, arseniuretted hydrogen, toluylene-diamine, snake venom, etc.

2. *Toxaemic*, caused by the toxins set free by specific pathogenic organisms—for example, typhoid fever, paratyphoid fever, malaria, yellow fever, relapsing fever, typhus fever, septicaemia, pyaemia, etc. In the first two of these diseases the jaundice is due to an infective cholangitis—

that is, it is hepatogenous in type, while in the remaining diseases there is in addition increased haemolysis, so that the term "haemohepatogenous" applies to the type of jaundice.

3. *The Epidemic or Infective Jaundice of Campaigns and Weil's Disease.*—Both of these diseases are types of toxæmic jaundice and should really be classed with the preceding group. Weil's disease is a special type of infectious jaundice, due to infection with the *Bacillus proteus*. Its symptoms are very similar to those of the epidemic jaundice of campaigns, but are of a more acute and severe type.

4. *Icterus Gravis, or Acute Yellow Atrophy of the Liver.*—This condition is really a "symptom complex," the result of cessation of liver function consequent on extreme degenerative changes in the liver cells. The symptoms of acute yellow atrophy of the liver are identical with those of the grave cases of either the toxic or toxæmic types of non-obstructive jaundice—for example, tetrachlorethane jaundice.

5. Other Special Types of Jaundice:

I. Hereditary icterus.

II. Icterus neonatorum due to:

- (1) The physiological haemolysis occurring with the circulatory changes at birth;
- (2) Congenital absence of the bile or hepatic ducts;
- (3) Congenital syphilis;
- (4) Septic pylephlebitis due to septic inflammation spreading from the umbilical cord.

PATHOLOGY OF "EPIDEMIC JAUNDICE OF CAMPAIGNS."

Post-mortem examinations were made on two fatal cases in this series of cases.

Post mortem Appearances.

There was the usual bile staining of the skin and tissues associated with a case of deep jaundice.

Small Intestines.—The duodenum showed a marked red velvety appearance of the mucous membrane, which was swollen. There was congestion of the ileum in one case; this was most marked in the lower half. It was much less intense than that of the duodenum.

The common bile duct showed redness and swelling of the mucous membrane. This catarrhal condition had spread up the cystic duct and into the hepatic ducts.

The gall bladder was distended in one case with a thin semi-purulent greenish fluid, from which paratyphoid B organisms were obtained.

The liver showed a pale yellowish appearance and some bile staining. The fatty degeneration was more marked in patches.

The heart showed dilatation, which was especially marked in the right auricle and ventricle.

The heart muscle was somewhat pale and showed some degenerative changes. In one case an ante-mortem thrombus was present in the right auricle and ventricle. A portion of this had become dislodged and caused an infarct in the lower lobe of the right lung.

The kidneys showed some degenerative changes of the epithelium.

In neither of the above cases was there any complete mechanical obstruction of the larger bile ducts.

Duodenitis.

In the above cases a marked duodenitis had occurred. In one case this was primary, in the other it had probably spread from a paratyphoid infection of the lower intestine.

The common bile duct and larger bile ducts showed marked catarrh spreading along their course and causing a definite cholangitis.

There were fatty changes present in the liver, and also in the kidneys and heart muscle.

The duodenitis had given rise to a cholangitis, which caused obstruction not in the large bile ducts but in the smaller ducts in the liver itself.

As a consequence of the toxæmia associated with the disease, fatty degeneration had occurred in the liver cells, and to a less extent in the kidney, epithelium and heart muscle. These degenerative changes caused impairment of function of the liver, and auto-intoxication, so that the terminal symptoms of both the fatal cases of jaundice were those of a toxæmia such as is observed in acute yellow atrophy.

The pathological condition found in the two fatal cases of epidemic jaundice described, was almost identical with that observed in cases of tetrachlorethane poisoning which I have described elsewhere.³ In each condition the jaundice is deep and due to a cholangitis, causing block-

ing of the finer bile ducts in the liver itself. In each duodenitis is marked.

In tetrachlorethane poisoning the poison is of a deadly nature, producing marked fatty degeneration of the liver cells, and so much consequent auto-intoxication that a fatal result is common, and the prognosis always grave when the jaundice is deep. The terminal symptoms are exactly similar to those of acute yellow atrophy.

In epidemic jaundice, fortunately, the toxin from the bacterial infection is less deadly in nature, so that fatty degeneration of the liver cells or those of the kidney or heart is very rare, consequently symptoms of auto-intoxication such as occur in the late stages of tetrachlorethane poisoning or in acute yellow atrophy are very rare.

THE BACTERIOLOGY OF EPIDEMIC JAUNDICE.

In a few of the cases examined a paratyphoid organism, usually of the "B" type, was found, but in the great majority of the cases of epidemic jaundice special tests for paratyphoid "A" and "B" were negative.

Captain Archibald, R.A.M.C., made blood cultures from several cases while in the pyrexial stage, before the development of jaundice, but the results were negative. Blood culture tests, after the development of jaundice, likewise proved negative.

The specific organism which is the cause of epidemic jaundice of campaigns has yet to be isolated.

It is interesting to note that in a small outbreak of infectious jaundice investigated at Bruyères, France, by Dr. Carnot and Dr. Weill-Halle,⁴ an organism of the paratyphoid group was isolated from the stools. The organism did not correspond to either the "A" or "B" varieties of paratyphoid. The cases occurred in the civil population.

SUMMARY.

The epidemic jaundice of campaigns thus appears to start as a gastro-intestinal infection, the inflammatory catarrh being most marked in the duodenum.

At this stage pyrexia and a certain amount of toxæmia occurs, but there does not appear to be a general blood infection usually, since blood cultures have generally been negative. A catarrhal cholangitis follows from spread from the duodenum, and marked jaundice now sets in, due to obstruction in the finer bile ducts.

The jaundice is hepatogenous in type and does not appear to be associated with increased haemolysis of red blood corpuscles, anaemia being absent.

Fortunately, most cases do not progress beyond this stage, and the catarrhal condition subsides with clearing up of the jaundice. In very exceptional cases the infective condition may give rise to degenerative changes in the liver, and symptoms of icterus gravis will then supervene.

It is interesting to note that sometimes mild gastro-enteritis occurs in cases exposed to similar conditions, and that in many of them jaundice will develop, while in a few it will not. It has been thought that as regards the infection and toxæmia associated with it the two groups of cases were similar.

Catarrhal Jaundice of Campaigns.

This is very common, and it must be classed etiologically with epidemic jaundice. When on campaign numerous cases of epidemic jaundice of the type described above are occurring there will also occur with them many cases in which there is no pyrexia or splenic enlargement.

These cases are undoubtedly due to an infection of a mild type, similar to that of the epidemic cases, and the asthenia and nervous weakness of the two conditions are very similar.

The French school have long regarded catarrhal jaundice as a benign form of infective jaundice, and this view appears to be correct as regards the catarrhal jaundice of campaigns.

Toxæmic Jaundice.

In cases of jaundice symptoms of any specific infection which may be the primary cause of the jaundice should always be looked for.

The clinical symptoms will usually indicate this type of jaundice—for example, the prolonged pyrexia of typhoid and paratyphoid is unlike that of epidemic jaundice, the rigor and very high temperature of malaria; the early delirium and profound toxæmia of relapsing fever

are quite distinctive. In every case of jaundice any accompanying specific infection should be elucidated without delay by means of appropriate pathological investigations.

ETIOLOGY.

Since the causal agent of "epidemic jaundice of campaigns" is not known with certainty, the etiological factors cannot be stated with precision. It is certain that the insanitary conditions inevitably associated with military campaigns play a most important part.

Food.—The infection is almost certainly conveyed by the alimentary tract, and contamination of food with infected dust probably plays a most important part in the causation. Flies, also, as in paratyphoid and typhoid fever, may convey infection to food; but they are probably not the main cause of the spread of the disease, since, in the Dardanelles area epidemic, jaundice occurred after the flies had largely disappeared.

Water.—The infection may be conveyed by water, but cases occurred where this channel of infection could be excluded.

Carriers of the disease very probably, as in paratyphoid and typhoid fevers, are responsible for the spread of infection.

Air.—In civil practice outbreaks of epidemic jaundice have been described⁴ in which the evidence pointed to the disease being air-borne and conveyed by the respiratory tract. Thus infection was spread in day schools amongst children sitting at the same desk.

Probably in the "epidemic jaundice of campaigns" the infection is almost entirely gastro-intestinal in its mode of spread, since air-borne infection was not observed—for example, epidemic jaundice was not observed to be conveyed in hospitals from one patient to another, when isolation of the jaundice cases was not carried out.

PROPHYLAXIS.

As regards prophylaxis, careful attention to latrines, to prevent spread of infection by dust and flies, is most important. Fly and dust proof latrines are very valuable as regards prevention. Refuse destruction by means of incinerators is most important.

The greatest care possible should be paid to prevent contamination of food and water.

Patients suffering from epidemic jaundice should receive hospital treatment in order that spread of infection may be guarded against.

Notification of jaundice cases is a most important prophylactic measure in order that immediate preventive measures may be instituted.

TREATMENT.

Rest in bed in the early part of the disease should be insisted upon. Careful dieting, which will be mainly liquid, is important.

It must be remembered that on campaign the milk will, owing to its sterilization, be devoid of anti-scorbutic and anti-beri-beri vitamins, so that some articles of diet should be given to counteract that deficiency. Thus fresh lemon juice in lemon drink is important. Porridge, pea-flour in soups, mashed potato, yeast in some form—for example, dried yeast added to hot milk, or yeast cakes made into a paste with milk—are important additions to the dietary. Soups to which fresh vegetables are added are valuable.

Owing to the anorexia present, the diet must necessarily be quite light. Excess of protein should be avoided, and meat is best not given until the jaundice is clearing up.

As regards medicines the following mixture may be given with advantage:

Sod. bicarb.	gr. xx
Potass. citrate	gr. xxx
Sod. sulph.	gr. xxx
Syrup. aurantii	3j
Aqua	ad	3j
t.d.s.				

Urotropin gr. x t.d.s. in water, as a gastro-intestinal antiseptic seemed to do good in many cases. Calomel should not be given in repeated doses, since it appeared that patients suffering from epidemic jaundice were very susceptible to the effect of calomel thus given. In some

cases mercurial stomatitis occurred. There is, however, no objection to giving a single dose of calomel in the early stages.

The cases almost without exception progressed favourably under treatment, though, as described above, convalescence was often somewhat slow.

For valuable help in the above work my thanks are due to Captain Archibald, R.A.M.C., for placing his bacteriological results at my disposal; also to Lieutenant-Colonel Crawford and Lieutenant Collins, R.A.M.C., of No. 18 Stationary Hospital; to Major MacMunn, R.A.M.C., of No. 15 Stationary Hospital; to Major Lewis, R.A.M.C., and to Lieutenant Corbett, R.A.M.C., of No. 16 Stationary Hospital, for valuable help and co-operation.

THE TREATMENT OF TOXIC JAUNDICE DUE TO TETRACHLORETHANE POISONING.

BY

WILLIAM HENRY WILLCOX, M.D., F.R.C.P.LOND.,

LIEUTENANT-COLONEL R.A.M.C.,

PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON, W.

The subject of toxic jaundice from tetrachlorethane poisoning was fully dealt with in a paper read before the Medical Society of London, March 1st, 1915.¹

It was pointed out that this type of toxic jaundice was of frequent occurrence amongst the workers in aeroplane factories, who were exposed to the vapour of the "dope" or cellulose varnish used for the wings of aeroplanes. One of the constituents of the dope or cellulose solution is tetrachlorethane. It was shown that the vapour of the tetrachlorethane in the dope, if inhaled for long periods, as occurred in the case of aeroplane workers, was likely to give rise to malaise and jaundice, and that this jaundice was of a serious type, and in severe cases often terminated fatally. The pathology of the condition showed that the jaundice was due to a cholangitis set up in the smaller bile ducts, causing an obstruction to the flow of bile from the liver, and also there was present marked fatty degeneration of the liver cells.

In severe cases this fatty degeneration was followed by necrosis of the liver cells and symptoms of autointoxication identical with those of acute yellow atrophy of the liver.

Did the patient survive the effect of necrosis of some portion of the liver, then the affected area became replaced by fibrous tissue; that is, a replacement fibrosis occurred and symptoms of portal obstruction—for example, ascites, etc.—resulted.

The jaundice of tetrachlorethane poisoning was found to be "hepatogenous" in type. It was not associated with haemolysis or anaemia, and no changes in the red blood corpuscles were observed.

The kidneys in severe cases showed degenerative changes—for example, fatty degeneration.

Pathology.

It is important that the pathology of this type of jaundice be thoroughly understood in order that the treatment of cases can be carried out on right lines.

Early Symptoms.

Obviously the first indication of the treatment of an early case is the removal of the patient from all influence of the poison. The presence of anorexia, drowsiness, general malaise, constipation, headache, and occasional vomiting, are quite sufficient indications for this step to be at once taken in the case of aeroplane workers.

The above early symptoms are the first indications of the poisoning, and treatment should be at once commenced. Unless at this stage the patient is removed entirely from the toxic action of tetrachlorethane, jaundice is almost certain to supervene and render the prognosis much more serious.

It is thus seen how important is the periodical medical inspection of factories where tetrachlorethane is used.

Classification of Cases.

From the point of view of treatment cases may be divided up into—

- I. Early cases with little or no jaundice (pre-jaundice stage).
- II. Cases with jaundice but not marked toxæmia.
- III. Cases with jaundice and marked toxæmia (acute yellow atrophy or icterus gravis type).
- IV. Cases with signs of hepatic fibrosis (replacement fibrosis) and portal obstruction.

In all cases of toxic jaundice of the type described, since the liver is profoundly affected and as the kidney may likewise be affected, it is important to relieve these organs as much as possible by giving a diet which is easily digestible and in which the protein and extractives are reduced as much as possible. Also all toxic drugs should be avoided.

I. Early (Pre-jaundice) Cases.

These patients should have light diet—for example, milk, fruit, vegetables, milk puddings, toast or bread. Meat, meat extracts, soups, and alcohol should be avoided. Tea or coffee may be given owing to their diuretic action, and the effect of the theine or caffeine present is to relieve the headache.

The bowels should be kept open by an initial suitable aperient—for example, aloes and cascara, to which podophyllin or colocynth may be added. A single dose of calomel, say 2 or 3 grains, may be given, but it must be remembered that in toxic jaundice cases of all kinds repeated small doses of calomel are to be avoided. These patients are very susceptible to their influence, and there is serious risk of mercurial stomatitis resulting.

Lemon drink, or the imperial drink used in hospitals, may be freely taken:

Potassii tartratis aciduli	3j
Syrup. limonis	3jss
Aquam	ad Oj

For medicine—

Sod. sulphate	3ss to 3j
Potass. citrate	gr. xl
Sod. bicarb.	gr. xx
Syrup. aurantii	3j
Aq.	ad 3j

t.d.s.

should be given so that the bowels may be kept open. Rest and fresh air are advisable, and the patient should be kept free from toxic influences of all kinds. Rest in bed is not essential. The room occupied by the patient should be well ventilated and the air kept fresh and pure.

II. Cases with Jaundice but not Marked Toxæmia.

The treatment should be on the general lines, as described under I. Rest in bed is essential.

Diet should be liquid if there is any tendency to vomiting—for example, whey, citrated milk (2 grains of sodium citrate to the ounce), raisin tea (made by boiling up $\frac{1}{2}$ lb. of broken raisins with 1 pint of water and straining), Benger's food; tea and coffee may be taken. The bowels should be kept loose by means of aperients and the sodium sulphate mixture given above. All toxic drugs should be avoided—for example, all forms of opium or its preparations and alkaloids are particularly harmful, since these patients are extremely susceptible to their influence. Chloroform—for example, chloroform water or spirits of chloroform—should not be given.

As a rule these cases improve and the jaundice gradually clears up. It is remarkable how long in even mild cases the jaundice persists. The cases do well unless toxic symptoms develop, and then further special treatment is necessary.

Cases of this type should not be allowed to return to work until at least a month has elapsed after the complete clearing up of the jaundice, and the work should not necessitate any further exposure whatever to the vapour of tetrachlorethane.

III. Jaundice with Marked Toxic Symptoms.

The symptoms which indicate toxæmia are vomiting, wandering or delirium, stupor, drowsiness, twitchings, or coma. The urine may become diminished in quantity, and the presence of albumin or casts are grave signs. Leucin or tyrosin in severe cases may be found in the deposit, and there may be acetoneuria.

In cases of jaundice with toxic symptoms of any kind the bowels should be kept well open. The following mixture should be given every three hours:

S.d. citrate	3j
Sod. bicarb.	gr. xxx
Potass. citrate	3ss
Caffeine citrate	gr. iij
Syr. aurant.	3j
Aq.	ad 3j

Infusion of normal saline Oij into a vein should be given once or twice a day until the toxic symptoms improve.

Subcutaneous injections of normal saline Oj to Oij may be given instead of the intravenous injections.

Rectal injection of sodium bicarbonate 3ij, normal saline Oj, should be given every eight hours.

The diet should be on the lines of that for cases Type II.

In cases in which there is suppression of urine, cupping over the lumbar region and electric light baths given in bed, or hot-air baths, may be employed with advantage.

The prognosis in cases of this type is always grave. The elimination of toxins should be aimed at as far as possible, and saline infusion into a vein subcutaneously and rectal salines should be given early with this object.

Alkali producing drugs such as citrates and bicarbonates are given to counteract the tendency to acid intoxication.

In cases of toxic jaundice I, II, or III the symptoms due to the jaundice *per se*—that is, pruritus, skin symptoms, etc.—are not sufficiently marked to call for any special treatment.

IV. Cases showing Signs of Portal Obstruction.

These cases are rare. Rest in bed and light diet, as indicated under Type II, are important. Aperients should be given and the sodium sulphate mixture given above should be taken. Potassium iodide gr. x may be added with advantage to the mixture.

Where ascites is marked and is causing dyspnoea or distress paracentesis should be performed. A convenient indication for resort to this measure is afforded by observing the level of the ascitic fluid with the patient propped up in bed. If the dullness due to the fluid reaches above the umbilical level then artificial removal of the ascitic fluid should be carried out.

One case of this type after paracentesis had been performed twice, over 20 pints being removed on each occasion, made a complete recovery.

THE TREATMENT OF KALA-AZAR (INDIAN FORM) BY TARTAR EMETIC INTRAVENOUSLY AND BY INUNCTIONS OF METALLIC ANTIMONY.

BY

SIR LEONARD ROGERS, M.D., F.R.C.P., I.M.S.,

PROFESSOR OF PATHOLOGY,

AND

CAPTAIN N. H. HUME, M.B., I.M.S.,

FIRST RESIDENT SURGEON, PRESIDENCY GENERAL HOSPITAL, CALCUTTA.

ONE of us (L. R.) early in 1915¹ commenced the use of tartar emetic intravenously in the treatment of kala-azar on the strength of its previous use in sleeping sickness, and independently of any other worker, although, as he subsequently learnt, Drs. Cristana and Caronia had previously given it successfully in the African form of kala-azar in Sicily, and he has already reported favourable results from its use in the Medical College Hospital.² Owing to difficulties in following up Indian patients, the European General Hospital presents better opportunities for determining the ultimate results of the new treatment, so during the last seven months we have been treating a consecutive series of cases of kala-azar among Europeans with tartar emetic, and are now able to form definite ideas of its value. All the intravenous injections have been given by one of us (N. H. H.), while the microscopical examinations of the specimens obtained by spleen puncture and the blood counts have been made by the other. The following

brief accounts of the cases will suffice to allow the results to be judged.

CASE I.

A European male, aged 18, admitted February 23rd, 1915, for fever of six weeks' duration, with his spleen down to the navel. Red corpuscles 3,660,000, white 2,000, ratio of white to red 1 to 1,830, as in kala-azar. He was treated with alkalis internally, and later was given a subcutaneous injection of oil of turpentine, but the fever, of an intermittent and low remittent type, continued, and by the beginning of July he had lost 5 lb. in weight, being now only 89 lb. 10 oz.

Spleen puncture was now performed, and numerous Leishman-Donovan bodies were found. Intravenous injections of a 2 per cent. solution of tartar emetic were therefore commenced, beginning with $\frac{1}{2}$ to 1 c.cm., soon raised to 3 c.cm., and gradually increased up to 9 c.cm., containing 18 cg. of tartar emetic. He very soon began to gain weight steadily, while the temperature declined to a slight intermittent rise to between 99° and 100° F. Two months after the commencement of the injections, when he had received a total of 140 cg. of tartar emetic, the fever finally ceased. Spleen puncture was again performed three weeks after the temperature had been quite normal, and no parasites could be found. By five weeks after the cessation of the fever he had gained 16 lb. 4 oz. since the commencement of the treatment, and was discharged "cured." He has been seen again recently, three months after leaving hospital, during which he has been at work. The spleen can no longer be felt, while the blood shows 5,750,000 red and 8,500 white corpuscles, so he may be considered to be completely cured.

CASE II.

A European male, aged 28, who had been in hospital during June, was readmitted on August 2nd, 1915, for fever of seven months' duration with enlargement of the spleen to 1 in. below the navel, and of the liver 1 in. below the costal margin. Red corpuscles 2,990,000, leucocytes 1,375, ratio of white to red 1 to 2,174, being thus characteristic of kala-azar. Spleen puncture was performed, and Leishman-Donovan parasites found; intravenous injections of tartar emetic were commenced, and the doses increased up to 8 c.cm. of the 2 per cent. solution. After a total of 96 cg. had been given in the course of six weeks, the temperature became normal. When he left hospital at his own request on October 4th, 1915, he had gained 8 lb. in weight, while his spleen only extended 2 in. below the costal margin. As he left Bengal we have not been able to obtain his further history, but, judging from the other cases, there is good hope of his having completely recovered.

CASE III.

A European male, aged 23, was admitted on December 21st, 1914, for fever of six months' duration; the spleen was enlarged to 3½ in. below the ribs, and he had cough with râles in the lungs, and diarrhoea. He was greatly emaciated, weighing only 6 st. The fever continued during the next six months, and no appreciable improvement occurred.

Spleen puncture was performed on June 28th, 1915, and numerous Leishman-Donovan parasites found. The blood now showed red corpuscles 2,960,000, leucocytes 1,125; ratio of white to red 1 to 2,631. Although it was recognized that the kala-azar infection was complicated by tuberculous disease of the lungs and bowels, and his case was a most unfavourable one, intravenous injections of tartar emetic were commenced on July 27th, but had to be omitted during September on account of the diarrhoea being worse; only a few doses up to a maximum of 6 c.cm. of the 2 per cent. solution could be given during the following two months, when the treatment was discontinued, after a total of 56 cg. of tartar emetic had been given, owing to the pulmonary phthisis having progressed to a serious degree. On December 10th, 1915, a second spleen puncture was performed, and no parasites could now be found, but as the specimen showed but little spleen pulp this negative result is open to possible doubt. The patient succumbed to tuberculous disease on December 27th, 1915, and no autopsy could be obtained. The spleen had become greatly reduced before his death. In this case the tartar emetic injections appear to have been successful in dealing with the kala-azar infection, but were powerless against the pulmonary tuberculosis.

CASE IV.

A European male, aged 36, was admitted on May 13th, 1915, for fever of a year's duration, contracted in Assam, with a double rise of temperature at times. The spleen was enlarged to a little below the navel and hard. The liver was not felt. Red corpuscles 3,850,000, white 1,125; ratio of white to red 1 to 3,422. Weight 99 lb. 4 oz. The temperature was of a low remittent type, from 99° to 101° F. There was no material change during the first two and a half months in hospital.

Spleen puncture was performed on June 26th, but only blood with no spleen pulp was obtained, and parasites were not found. On repeating the puncture on August 5th Leishman-Donovan parasites were found and injections of tartar emetic were commenced. After five weeks' treatment, during which 78 cg. of the drug had been given, the temperature became normal, but the injections were continued for eleven weeks more and pushed up to 10 c.cm., or 20 cg. at a time, a grand total of 326 cg. in all having been given. On December 7th spleen puncture was again performed, with a negative result as regards parasites. On December 12th the blood showed red corpuscles 5,160,000, white 10,250; ratio of white to red 1 to 503—a most remarkable improvement up to fully the normal point.

He had gained 20 lb. in weight, while the spleen only extended one inch below the ribs, and when he left hospital he was well on the road to complete recovery. He has been seen since, and remains in good health.

CASE V.

A European male, aged 36, who had been in hospital during the previous year for kala-azar, and improved greatly on the alkaline treatment described by one of us (L. R.) in a previous paper.³ He was readmitted in an emaciated and anaemic condition, and stated that he had suffered from fever for the past two months, with a double rise of temperature on some days. The spleen was greatly enlarged, extending some 2 in. below the navel, and fever of an intermittent and low remittent type was present.

On July 17th spleen puncture was performed and Leishman-Donovan parasites found in small numbers, so tartar emetic injections were commenced. He soon began to gain in weight, and his temperature fell to normal, but after three weeks he developed bronchitis, and for twenty days was in a most critical condition, during which the injections were suspended. On improvement in his general condition taking place the tartar emetic injections were resumed and the dose gradually pushed up to 10 c.cm. of the 2 per cent. solution, and by late in December 307 cg. had been given. The temperature had now been normal for over two months, during which he had increased 14 lb. in weight and was gaining daily in strength. Spleen puncture was now repeated, with a negative result, while his blood showed 5,120,000 red corpuscles and 6,750 white, the ratio of white to red being 1 to 578, and he has recently been discharged as "cured."

The improvement in this patient has been most remarkable, and we have every reason to expect a complete recovery from a very advanced stage of kala-azar.

CASE VI.

A European male, aged 28, was admitted on October 4th, 1915, for fever of four months' duration and enlargement of the spleen to 3 in. below the costal margin and 1½ in. to the right of the navel. The blood showed 4,250,000 red corpuscles and 2,375 white, the ratio of white to red being 1 to 1,970.

Spleen puncture showed numerous kala-azar parasites. Intravenous injections of tartar emetic were at once commenced and 124 cg. had been given by the end of six weeks, when the treatment had to be suspended for three weeks owing to the inflamed state of the elbows due to the escape of a little of the highly irritating solution around the veins. Spleen puncture now revealed two degenerate-looking, badly-staining parasites only after a long search, and on January 7th, 1916, a further spleen puncture showed no parasites. The blood now showed 3,750,000 red and 3,250 white corpuscles, being 1 white to 1,098 red. He had now been free from fever for two weeks and had gained 16 lb. in weight.

This patient has only been long enough under treatment to show very marked improvement, but, judging from the other cases recorded above, we have very good hope of his eventual recovery. His case is included to complete the series we have so far treated with tartar emetic intravenously.

INUNCTIONS OF FINELY DIVIDED METALLIC ANTIMONY IN KALA-AZAR.

One of us (L. R.) has already suggested and reported promising results from the inunction of finely divided metallic antimony in lanoline.² This simple method has great advantages in the case of children with small veins, who are also liable to be much frightened by such a procedure as spleen puncture. In the following case it appears to have been successful.

CASE VII.

A European girl, aged 15, was admitted for kala-azar of a year's duration, with intermittent fever and enlargement of the spleen to 6 in. below the ribs. She was fairly well nourished, and was a comparatively favourable case for treatment.

Spleen puncture showed Leishman-Donovan parasites. One drachm of a 5 per cent. antimony ointment was rubbed in over the abdominal wall every third day. Her weight at the commencement of the treatment was 5 st. 8 oz. At the end of five weeks the temperature remained normal, and on her discharge from hospital she had gained 12 lb. and greatly improved in her general condition, while the spleen had also decreased considerably. She has continued the treatment since she left hospital, and was heard from recently, when she was keeping free from fever and continued to improve in health, so there is good promise of her complete recovery.

CASE VIII.

Another European male child, aged 5, was admitted more recently with a history of fever for six months; there was marked emaciation, and the spleen extended 4½ in. below the ribs. He has now been treated for seven weeks with antimony inunctions. His temperature has fallen to normal, he is gaining weight and walking about, and appears to be much better. It is, however, far too early to say what will be the ultimate result, his case being included to complete the series which have been treated up to the time of writing this paper.

TECHNIQUE OF THE INJECTIONS AND DOSAGE.

The technique of the injections is very simple. A 10 c.cm. serum syringe is used, and the vein selected—usually either the median basilic or cephalic, or a prominent vein in the forearm—is made to stand out by tying a bandage round the upper arm, and by the patient clenching his fist. Tr. iodine is used to sterilize the skin. As soon as it is thought that the needle is in the vein the piston is withdrawn slightly, and a little blood is drawn up into a syringe; or, if a syringeful of the solution is to be given, the barrel is removed from the needle and a few drops of blood are allowed to flow before the solution is injected. Great care should be taken that the injection is made into the vein, and not into the tissues around the vein. The tartar emetic solution is very irritating, and a few minims injected under the skin cause great pain at the time of the injection, and later on a hard, tender, brawny swelling, or even sloughing of the tissues.

The symptoms which follow the injections have varied in different cases. Three patients had no untoward symptoms—one experienced a metallic taste in his mouth for several hours, a disinclination for food and vague abdominal discomfort. Another had a severe paroxysm of coughing and vomiting, which came on immediately after the injection, and lasted about ten minutes.

DOSAGE.

We began with only half to 1 c.cm. of the 2 per cent. solution, but rapidly increased it to 3 or 4 c.cm., and repeated the injection every two or three days, adding 1 c.cm. at each injection up to a maximum of 10 c.cm. if the patient had no marked gastric disturbance, in which case the dose may be reduced slightly for a time. In no case have any serious symptoms developed, although we have repeatedly given the large dose of 20 cg.

CONCLUSIONS.

The cases we have briefly recorded are a consecutive series and so are quite unselected. The uniform and rapid improvement in all except the unfortunate patient with tuberculous affection of the lung and bowels—who, indeed, also appears to have been much benefited as regards his infection with kala-azar—is quite unique in our experience of the disease, which, in the case of one of us, extends over almost twenty years, and includes a knowledge of nearly every case treated in the Calcutta European Hospital for the last fifteen years. Numerous recoveries of patients with kala-azar under other lines of treatment have been recorded by one of us,³ but only in occasional cases, while in the majority of them most disheartening failures were met with. We now have no hesitation in advising the use of intravenous injections of tartar emetic as a routine method of treating kala-azar, beginning with 4 to 6 cg. on alternate days, and increasing by one or two centigrams every other day up to a maximum of 20 cg., if the patient will tolerate as much. The treatment should be continued until the temperature has remained normal for several weeks with steady gain in weight, and the parasites are found to have completely disappeared from the spleen, and the leucocytes have been raised to about the normal level. It is not necessary to continue until the spleen has been reduced to its normal size, as it will continue to shrink after the injections are omitted.

In children and nervous female patients inunctions of antimony ointment, preferably in a strength of 10 per cent., is worthy of trial, although there is not yet sufficient evidence to decide how far this much simpler measure can be relied on. If further experience shows it to be able to cure the disease it will present manifest advantages, especially in out-patient and village practice.

We believe that in tartar emetic, and probably in other preparations of antimony, a specific treatment for the terrible lingering and very fatal kala-azar has at length been found, and yet another serious tropical disease been brought within the pale of curable affections.

ATTEMPTS TO PRODUCE A SAFE AND EFFECTIVE BACILLUS DYSENTERIAE (SHIGA) VACCINE FOR PROPHYLACTIC PURPOSES.

By J. D. THOMSON, A.M., M.B., C.M.

(From the Lister Institute.)

THE question of the prophylactic treatment of dysentery is of considerable importance, and the desirability of placing the subject on a satisfactory experimental basis is self-evident. As a preliminary contribution to this aspect of the question as it relates to the bacillary type of dysentery I venture to give the following general account of some experiments* carried out with *B. dysenteriae* (Shiga) at the Lister Institute of Preventive Medicine during the past year, and a summary of results so far obtained, with the conclusions drawn therefrom.

The vaccines that have been experimented with up to the present are:

I. Heated Vaccines (at 56° C. for one hour).

- A. Ordinary vaccines (non-sensitized).
- B. Vaccines treated with normal horse serum according to the method described and advocated by Broughton-Alcock in the BRITISH MEDICAL JOURNAL, August 18th, 1914.
- C. Vaccines treated with diluted specific Shiga-agglutinating serum.

II. Unheated Carbolyzed Vaccines.

- A. Ordinary carbolyzed vaccines ("non-sensitized").
- C. Carbolyzed vaccines treated with diluted serum, obtained from known immune rabbits.

Experimental Animal.

The rabbit was chosen as the experimental animal because of its susceptibility to the Shiga bacillus and because it reacts in a characteristic manner both to the bacillus and to its toxin.

Test for Immunity.

For this I relied on the intravenous injection of living bacilli. The intravenous injection of 200 million of living bacilli (twenty-four hours culture) in 1 c.cm. of normal saline, of the strain of Shiga which was used, was known to be almost invariably fatal to the normal healthy full-grown rabbit. Of ten strong healthy control rabbits that got 250 million intravenously, only one survived. To test if the vaccinated rabbits had acquired a reasonable degree of immunity, the dose usually given was 1,000 million of living bacilli (twenty-four hours culture) in 1 c.cm. of normal saline, given intravenously.

Summary of Animal Experiments.

Four series of experiments were carried out. All vaccines were given subcutaneously. Heated vaccines were used in the first three series. These series differed from each other simply in respect of dose. Each series is further divided into three groups. In the "A" groups, ordinary (non-sensitized) vaccines were used; in the "B" groups, vaccines treated with normal horse serum; in the "C" groups, vaccines treated with diluted specific Shiga-agglutinating serum. In each case the serum was thoroughly removed by centrifugalizing and by washing. The deposit of "sensitized" bacilli was finally made into an emulsion of known strength in fresh normal saline. In Group C₁ the vaccine was sensitized and washed before it was heated, in Groups C₂ and C₃ the vaccines were first heated and then "sensitized."

SERIES I.

Group A₁—Vaccines used, ordinary (non-sensitized), heated at 56° C. for one hour.

Doses given: First, on January 14th, 200 million; second, on January 25th, 400 million; third, on February 4th, 800 million.

Of 20 rabbits that formed this group, 5 did not survive the first dose; 1 survived the first but not the second dose; 1 survived the first and second but not the third dose; 13 survived all three doses.

Each of the 13 that survived all three doses was given as a test dose 1,000 million of living bacilli (twenty-four hours Shiga culture) in

* Complete protocols of these experiments will appear, it is hoped, in a future number of the *Journal of the Royal Army Medical Corps*.

† Further experiments with unheated vaccines are now being carried out. These will include vaccines sensitized with undiluted specific Shiga serum from highly immune rabbits, prepared according to the method found successful in the case of vaccines used for therapeutic purposes by Gordon (*Proceedings of the Royal Society of Medicine, Therapeutical and Pharmacological Section*, 1913, vol. vi, pp. 153-176).

1 c.c.m. of normal saline intravenously—6 on February 19th and 7 on February 23rd. Of these, 12 survived and 1 died about a month later, probably as a result of the test dose.

Group B₁.—Vaccine used, "sensitized" with normal horse serum after it had been heated at 56° C. for one hour.

Doses given: First, on January 18th, 200 million; second, on January 29th, 400 million; third, on February 8th, 800 million.

Of 23 rabbits that formed this group, 12 did not survive the first dose. In 4 of these the fatal issue was complicated by pregnancy; 1 survived the first but not the second dose; 7 survived all three doses.

Each of the 7 that survived all three doses was given as a test dose 1,000 million of living bacilli (twenty-four hours Shiga culture) in 1 c.c.m. of normal saline intravenously on February 23rd. Of these, 6 survived and 1 died as a result of the test dose.

Group C₁.—Vaccine treated with dilute specific Shiga-agglutinating serum before it was heated.

Doses given: First, on January 26th, 200 million; second, on February 6th, 400 million; third, on February 16th, 800 million.

Of 20 rabbits that formed this group, 12 did not survive the first dose. In one pregnancy and in another pseudo-tuberculosis complicated the fatal issue; 8 survived all three doses.

Each of the 8 that survived all three doses was given, as a test dose, 1,000 million of living bacilli (twenty-four hours Shiga culture) in 1 c.c.m. of normal saline intravenously on March 3rd. Of these, 7 survived, and 1 died of marasmus as a result of the dosage.

SERIES II.

In this series all the rabbits were inoculated on the same days, the doses being the same for each group—namely: First, on February 11th, 100 million; second, on February 22nd, 300 million; third, on March 4th, 900 million.

Group A₂.—Vaccine used, ordinary (non-sensitized) heated at 56° C. for one hour.

Of 6 rabbits that formed this group, 2 did not survive the first dose. In 1 of these the fatal issue was complicated by the presence of pseudo-tuberculosis; 4 survived all three doses.

Each of the 4 that survived all three doses was given as a test dose 1,000 million of living bacilli (twenty-four hours Shiga culture) in 1 c.c.m. of normal saline intravenously on March 20th. All 4 survived.

Group B₂.—Vaccine heated at 56° C. for one hour, and afterwards sensitized with normal horse serum.

Of 6 rabbits that formed this group, 3 did not survive the first dose, 1 survived the first and second but not the third dose, 2 survived all three doses.

Each of the 2 rabbits that survived all three doses was given as a test dose 1,000 million of living bacilli (twenty-four hours Shiga culture) in 1 c.c.m. of normal saline intravenously on March 20th. One died on the following day, and *post-mortem* examination revealed an advanced stage of pseudo-tuberculosis. The other survived.

Group C₂.—Vaccine heated at 56° C. for one hour and afterwards treated with diluted Shiga-agglutinating serum.

Of 6 rabbits that formed this group, 2 did not survive the first dose (1 of these was pregnant); 1 survived the first and second but not the third dose; 3 survived all three doses.

Each of the 3 rabbits that survived all three doses was given as a test dose 1,000 million of living bacilli (twenty-four hours Shiga culture) in 1 c.c.m. of normal saline intravenously on March 20th. One became completely paralysed in its hind quarters and died on the sixteenth day after receiving the test dose. The remaining 2 survived the test dose.

SERIES III.

In this series also all the rabbits of each group were inoculated on the same days, the doses being the same for each group—namely: First, on April 28th, 25 million; second, on May 8th, 100 million; third, on May 18th, 500 million.

Group A₃.—Vaccine, ordinary (non-sensitized), heated at 56° C. for one hour.

Of 10 rabbits that formed this group, 1 did not survive the first dose. The *post-mortem* examination revealed old lesions in mesenteric glands and in liver; 1 survived the first but not the second dose—it had young after the second dose; *post-mortem* examination revealed old-standing disease of the lung; 8 survived all three doses.

Of the 8 that survived all three doses, 1 died before the test dose was due, and the cause of death in this case was complete prolapse of the womb during parturition.

Of the remaining 7, 2 got as a test dose 500 million of living bacilli in 1 c.c.m. of normal saline intravenously on July 13th—1 survived and 1 died; 3 got as a test dose 1,000 million of living bacilli intravenously, 2 on June 4th, and 1 on July 13th—2 survived and 1 died as the result of this test dose; 2 got as a test dose 1,500 million of living bacilli in 1 c.c.m. of normal saline intravenously—1 survived, and 1 died on the third day after this dose. The immediate cause of death was pneumonia.

Group B₃.—Vaccine heated at 56° C. for one hour, and afterwards sensitized with normal horse serum.

Of 10 rabbits that formed this group, 2 did not survive the second dose, or surviving the ten days, were too ill to get a third dose. In both "abortion" occurred; 8 survived all three doses.

Of the 8 that survived all three doses, each of 2 got 500 million of living bacilli in 1 c.c.m. of normal saline intravenously on July 13th; both survived this test dose. Each of 4 got 1,000 million of living bacilli in 1 c.c.m. of normal saline intravenously as test dose, 2 on June 4th, and 2 on July 13th; all 4 survived. Each of 2 got 1,500 million of living bacilli in 1 c.c.m. of normal saline intravenously on July 13th; 1 survived and 1 died as a result of this dose.

Group C₃.—Vaccine heated at 56° C. for one hour, and afterwards treated with diluted Shiga-agglutinating serum.

Of 10 rabbits that formed this group, 1 did not survive the third dose; 9 survived all three doses.

Of the 9 that survived all three doses, each of 2 got 500 million of living bacilli in 1 c.c.m. normal saline intravenously on July 13th—both survived this test dose; 1 got 750 million of living bacilli in 1 c.c.m. normal saline intravenously on July 13th—survived. Each of 4 got 1,000 million of living bacilli in 1 c.c.m. normal saline intravenously, 2 on June 4th, 2 on July 13th; 3 survived, and 1 died as a result of this dose. Each of 2 got 1,500 million living bacilli in 1 c.c.m. normal saline intravenously as a test dose on July 13th; both survived.

In all the above three series the vaccine used had been heated at 56° C. for one hour. During the course of some complement fixation experiments, undertaken with the idea of finding some guide to the dilutions of bacilli and of specific serum which, when mixed together, would give the optimum sensitization of the bacilli, it was found that very little fixation of complement took place in any dilution if the bacillary emulsion had been first heated to 56° C. for one hour, and that none at all took place if the bacillary emulsion had been heated to 62° C. for one hour or more. For a time it was supposed that this result was in some way connected with the death of the bacilli, and acting on this hypothesis the vaccine used for Group C₁ was prepared. Later on, other experiments showed that it is the heat that destroys the property of the emulsion to act as antigen, and that emulsions of Shiga made with freshly prepared carbolized saline (0.5 per cent. carbolic in normal saline) and left until sterile, still retain that property. For the next series of experiments, therefore, the vaccines were not heated.

SERIES IV.

This series was divided into two groups of A₄ and C₄.

For Group A₄, ordinary (non-sensitized) unheated carbolized vaccine was used. For Group C₄, unheated carbolized vaccine treated, when sterile, with diluted serum from known highly immune rabbits, was used. The dosage was the same for both groups. Each group was divided into two lots. Each rabbit in lots 1 got two doses only, 50 million for the first dose, and, ten days later, 100 million for the second dose. Each rabbit in lots 2 got, in addition, a third dose, 400 million, ten days after the second dose.

Of 14 rabbits that formed group A₄, 2 did not survive the first dose. In 1 *post-mortem* examination showed that the fatal issue was complicated by pseudo-tuberculosis. The remaining 12 were divided into two lots, as above. Six rabbits (lot 1) all survived their second dose. Six rabbits (lot 2) all survived their second and third doses.

Three weeks after their last dose of vaccine, lots 1 and 2 got test doses as follows: Of lot 1, 3 got 500 million living, intravenously, and 3 got 1,000 million; all survived. Of lot 2, 3 got 1,000 million living, intravenously—all survived; 3 got 2,000 million—2 survived and 1 died as a result of this test dose.

Of 14 rabbits that formed group C₄, 3 did not survive the first dose. The remaining 11 were divided into two lots. Six rabbits (lot 1) all survived their second dose. Five rabbits (lot 2) all survived their second and third doses.

Three weeks after their last dose of vaccine the 6 rabbits of lot 1 got test doses as follows: 3 got 500 million living intravenously, and 3 got 1,000 million; all survived.

The rabbits of lot 2 did not get test doses of living bacilli, but, as above mentioned, all survived their third dose of vaccine, while of two controls that got the same dose both died.

ANALYSIS OF RESULTS.

1. Toxicity of Vaccines.

This may be measured by the percentage of rabbits that died during immunization. Eliminating those rabbits in which the fatal issue was complicated by pregnancy, abortion, or by well marked chronic disease, we find that in our attempts to immunize rabbits with heated vaccines—Series I to III inclusive—

24.2 per cent. succumbed to ordinary non-sensitized vaccines.

43.3 per cent. succumbed to vaccines sensitized with normal horse serum.

39.4 per cent. succumbed to vaccines sensitized with diluted specific Shiga-agglutinating serum.

The numbers on which these percentages are based, namely, 33, 30, and 33 respectively, are small, but are approximately the same for each of the vaccines. Again, most of the deaths occurred after the first dose in Series I and II, and when the dosage was modified, as in Series III, the results were:

No death in 8 during immunization with ordinary non-sensitized serum.

No death in 8 during immunization with vaccine sensitized with normal horse serum.

1 death in 10 during immunization with vaccine sensitized with diluted specific Shiga-agglutinating serum.

With unheated vaccines only one series—Series IV—is available, and applying the same process of elimination as before, we find that

1 death in 13 occurred during immunization with non-sensitized vaccine.

3 deaths in 14 occurred during immunization with sensitized vaccine.

Toxicity may also be measured by the severity of general symptoms and by the effect on the weight of those animals that survived. Data on those points do not appear in the above summary of experiments, but it may here be stated in general terms that the bowel symptoms were most severe in Group C₁, where the vaccine used was sensitized before it was heated; that where comparatively large doses of heated vaccines were used the severer

symptoms referable to the central nervous system were most marked after "sensitized" vaccines, and that loss of weight was most marked after ordinary "non-sensitized" vaccines, but that this was less noticeable in Series IV, where the vaccines were unheated and where the dosage was less.

2. Immunity Conferred.

The fact that the numbers available for this analysis are still smaller and more unequal for each group than for the first analysis must be borne in mind when expressed in percentages. Although the conditions varied in each series, they were the same for each group of each series, so that, with the proviso made above with regard to percentages, we may quite fairly compare the "sensitized" and "non-sensitized" vaccines in respect of the immunity conferred.

First, then, considering Series I to III (heated vaccines) together, the numbers protected against the test doses given were:

- In "A" group (ordinary non-sensitized" vaccine), 20 out of 23; or approximately 87 per cent.
- In "B" group (vaccine sensitized with normal horse serum), 14 out of 16; or approximately 87 per cent.
- In "C" group (vaccine sensitized with diluted specific Shiga-agglutinating serum), 17 out of 20; or 85 per cent.

But if we take Series III by itself the figures are:

- In "A" group, 4 protected out of 6.
- In "B" group, 7 protected out of 8.
- In "C" group, 8 protected out of 9.

With unheated carbolized vaccines, only Series IV, consisting of two groups (Group A_u, in which ordinary non-sensitized vaccine was used, and Group C_u, in which the vaccine was treated with diluted serum from rabbits known to be highly immune), is available. The number of rabbits treated is small, but the results, so far as they go, indicate that, quite apart from sensitization, unheated carbolized vaccines give better immunity than vaccines that have been heated at 56° C. for one hour.

Local Reaction.

In the rabbit, in doses that can safely be given, the local reactions following Shiga vaccines are quite negligible. The rabbit, therefore, is not a suitable animal in which to study and compare the local reactions of Shiga vaccines. With *living* Shiga bacilli the case is different, and the following experiment may be cited as showing the difference in local reaction caused by the subcutaneous inoculation of large doses of *living* Shiga bacilli in immune as compared with that in unprotected rabbits.

1. Two healthy unprotected rabbits (Reference Nos. 14 and 15) got subcutaneously 2,000 million and 4,000 million of living Shiga bacilli respectively. On the following day there was in No. 14 a soft, prominent swelling of the subcutaneous tissues at the site of inoculation, and the skin over the centre of the swelling was purplish-red in colour. In No. 15, the swelling at the site of inoculation was somewhat more prominent, and the skin over it was mottled purple and red in colour. No. 15 died on the fourth day, and No. 14 on the fifth day after the inoculation. In both cases the skin over the centre of the swelling had necrosed, and on cutting into the swelling a central slough about $\frac{1}{2}$ in. thick at its centre, and thinning off towards the periphery, was exposed. The area of the necrosed skin and the slough were somewhat more extensive in No. 15 than in No. 14.

2. Two rabbits (Reference Nos. 3 and 6) that had each survived a dose of 200 million prepared vaccine on December 14th, 1914, were afterwards treated as follows. Each got on January 13th, 1915, 200 million, on January 20th 400 million, on January 27th 800 million, and on February 3rd 1,600 million of ordinary killed Shiga vaccine that had been heated at 56° C. for one hour. On May 27th No. 3 got 2,000 million and No. 6 got 4,000 million of *living* Shiga bacilli subcutaneously. In each case there was on the following day a soft puffy swelling of the subcutaneous tissue and some redness of the skin at the site of inoculation. Two days later the swelling was less puffy and the skin was less red. Ten days later there was still some puffy swelling in the case of No. 3 and a firm elongated swelling in the case of No. 6. The skin over the swellings was normal in appearance; the swellings themselves were much reduced in size and

later on gradually disappeared. Both rabbits remained well.

The above results suggest that the local reaction following the injection of vaccines used for therapeutic purposes in patients suffering from the disease—at all events, in chronic cases or in cases that have lasted for some considerable time—may be mild compared with that in normal persons, and workers using exclusively any particular vaccine for therapeutic purposes only may be misled as to its probable local reaction if used prophylactically in normal persons.

At the King George Hospital I understand that ordinary Shiga vaccine has been given to patients suffering from chronic dysentery of the Shiga bacillary type without its producing any local reaction, in doses that in normal persons have produced severe local reactions.

SUMMARY AND CONCLUSIONS.

1. *Toxicity.*—The toxicity of the vaccines studied has been determined by the liability of the initial dose to kill the experimental animals; and in those that survived by the severity of general symptoms, but more especially by the effect on the weight of the animals during the period of immunization.

In the series of animals in which moderate and large initial doses of vaccines were given, it was found that serum-treated vaccines were more fatal than untreated vaccines, and in the case of animals in which comparatively small initial doses were given the numbers are not sufficiently large to warrant us drawing a conclusion on this point.

With heated vaccines, bowel symptoms were most severe after the vaccine that had been treated with diluted specific Shiga-agglutinating serum *before* being heated. Symptoms referable to the central nervous system were, on the whole, most severe after serum-treated vaccines.

Serum-treated vaccines produced less loss of weight than untreated vaccines, but this was less noticeable in Series IV, where the vaccines were unheated and the dosage was less.

2. It has been found necessary to diminish the initial dose of vaccine in each succeeding series of rabbits, and the results obtained encourage the view that an initial dose at once relatively non-toxic and still able to immunize may be hoped for, though such a dose has not yet been established.

3. The first dose is the critical dose with all the vaccines used. Even with 50 million as a first dose, no less than four healthy animals died out of twenty-seven, while none died after 100 million given as a second dose.

4. The second dose should not be greater than twice the size of the first dose, though this ratio (1 : 2) may be exceeded in subsequent doses.

5. Heating should be avoided in the preparation of Shiga vaccines. It does not reduce their toxicity, and it destroys the antigen that calls forth the complement fixing body. Moreover, unheated vaccines may be sterilized by weak carbolic, freshly prepared, without losing the above-mentioned antigen; and these unheated carbolized vaccines gave in our experiments a better immunity.

6. Immunity, as tested by the power to withstand lethal doses of living bacilli given intravenously, was obtained with serum-treated and with untreated vaccines in apparently about equal degree. Whether the immunity obtained by the one is more lasting than that obtained by the other was not determined.

7. *Local Reactions.*—The rabbit is not a suitable animal on which to study and compare the local reactions caused by dead Shiga vaccines.

THE Accademia dei Lincei of Rome has awarded the King's prize of £400 for human physiology to Dr. Filippo Bottazzi, professor of physiology in the University of Naples. He is the author of a treatise on physiological chemistry and of memoirs on the metabolism of the red corpuscles, and other subjects.

It has been arranged to hold the Oxford Ophthalmological Congress as usual this year. It will assemble at Keble College on the evening of July 12th. The whole of the following day will be devoted to a discussion on the relation of ophthalmology to general medicine, to be opened in the morning by Sir William Osler and in the afternoon by Sir Anderson Critchett. Further particulars can be obtained from the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton.

NOTES ON DYSENTERY VACCINATION.

BY

ALDO CASTELLANI, M.D., M.R.C.P.

DYSENTERY vaccination is of such great practical importance that one wonders that so little attention, comparatively speaking, has been paid to it since the pioneer work of Kruse and Shiga. Such vaccination has never been used to any large extent, owing, I believe, to the following reasons:

1. Vaccines containing the Shiga-Kruse bacillus, prepared according to the usual technique (broth cultures killed by heat), give an extremely severe local and general reaction. I have seen persons incapacitated for work for more than two weeks after such inoculation. In the lower animals, too (rabbits), such vaccines produce very severe symptoms and sometimes death.

2. A vaccine prepared with Shiga-Kruse bacillus does not give immunity for forms of dysentery due to Flexner, Flexner-like, and other dysentery germs.

Peptone-Water Mixed Vaccine.

The only way to obviate these two drawbacks is to prepare the Shiga-Kruse vaccine by a method which will decrease its irritating properties, and to use a mixed vaccine instead of a mono-vaccine. I have carried out experiments on the subject since 1903 and 1904. In the *Ceylon Medical Reports* for 1904 I published the results I arrived at in that year. I stated that as the anti-dysentery vaccine prepared with broth cultures gives rise to very severe symptoms, great tenderness and redness of the skin, very often enlargement of the neighbouring glands, and fever, which may be very high, it had occurred to me to use peptone water cultures instead of broth cultures. This simple modification of the technique was most satisfactory; the irritating properties of the vaccine practically disappeared without apparently any distinct decrease in its immunizing power. I did not think this result was merely due to the fact that peptone-water cultures contained a smaller number of bacteria than broth cultures.

Preparation.

The Shiga-Kruse bacillus and three species of dysentery-like germs (paradysentery), common in Ceylon, were grown in peptone-water tubes for three days at blood temperature. They were then kept for one hour at the temperature of 60° C. Using all aseptic precautions, the different cultures were mixed in this proportion:

Dysentery	3 parts
Paradysentery No. 1	1 part
Paradysentery No. 2	1 "
Paradysentery No. 3	1 "

The resulting mixture was the vaccine, of which I inoculated 1 c.cm. (sometimes $\frac{1}{2}$ c.cm.), the injection being repeated one or two weeks later.

The inoculation was followed in most cases by practically no local symptoms. In other cases it was followed after five or six hours by mild signs of reaction—some little tenderness and redness of the skin at the place of inoculation. In some instances the temperature rose to 100° or 101° F.

The conclusions I came to were that the inoculation of the mixed peptone-water cultures vaccine was harmless and that the blood of the inoculated persons agglutinated the *Bacillus dysenteriae* (Shiga-Kruse) and the various strains of paradysentery with which the vaccine had been prepared, though the agglutinins were in small amount and disappeared after a short time.

Carbolized Mixed Dysentery Vaccine.

Since 1912 I have prepared and used in Ceylon a carbolized mixed dysentery vaccine, consisting of an emulsion of Shiga-Kruse, Hiss Y bacillus, original Flexner bacillus, a Flexner-like bacillus No. 1, isolated in Ceylon, a Flexner-like bacillus No. 2, also isolated in Ceylon.

Preparation.

The individual vaccines are prepared by making emulsion from twenty-four hours agar cultures, in normal salt solution (0.75 per cent.), to which 0.5 per cent. of carbolic acid had been added. All particulars of the technique are given in my

previous papers on the subject of mixed dysentery vaccines. The individual vaccines are standardized as follows per c.cm.:

Shiga-Kruse bacillus	1,000 million.
Flexner bacillus	1,000 "
Hiss Y bacillus	1,000 "
Flexner-like No. 1	1,000 "
Flexner-like No. 2	1,000 "

These vaccines are mixed in equal parts, so that 1 c.cm. of the mixed vaccine will contain 125 million of each of the organisms used.

Of this vaccine, 0.5 to 0.6 c.cm. is given hypodermically the first time, and the same amount after a week. The reaction is not very severe, though more marked as a rule than after the typhoid-paratyphoid vaccine. Agglutinins generally develop for all the germs of the dysentery group which have been injected, but their amount is not high, the agglutination limit seldom being higher than 1 in 40, and is somewhat inconstant and irregular; but the same may be said of individuals inoculated with simple mono-vaccines, Shiga-Kruse, Flexner, etc.

Combined Typhoid+Paratyphoid A+Paratyphoid B +Dysentery.

This combined vaccine, on which I have published several previous papers, consists of an emulsion of Shiga-Kruse, Hiss Y bacillus, original Flexner bacillus, a Flexner-like bacillus No. 1, isolated in Ceylon, a Flexner-like bacillus No. 2, also isolated in Ceylon, typhoid bacillus, paratyphoid A bacillus, and paratyphoid B bacillus.

Preparation.

The individual vaccines are prepared by making emulsions from twenty-four hours agar cultures in normal salt solution (0.75 per cent.), to which 0.5 per cent. of carbolic acid has been added.

The individual vaccines are standardized as follows per cubic centimetre:

Typhoid bacillus	4,000 million.
Paratyphoid A bacillus	1,000 "
Paratyphoid B bacillus	1,000 "
Shiga-Kruse bacillus	1,000 "
Flexner bacillus	1,000 "
Hiss Y bacillus	1,000 "
Flexner-like bacillus No. 1	1,000 "
Flexner-like bacillus No. 2	1,000 "

These vaccines are mixed in equal parts, so that 1 c.cm. of the mixed vaccine will contain 200 million of the typhoid bacillus and 125 million of each of the other organisms used.

Of this vaccine, 0.5 to 0.6 c.cm. is given hypodermically the first time, and the same or double the amount after a week. The reaction is severer as a rule than after the typhoid-paratyphoid vaccine. As regards agglutinins, the agglutination for the germs of the dysentery group is not high, the agglutination limit seldom being higher than 1 in 40; it is also somewhat irregular and inconstant, but to a certain extent the same may be said of individuals inoculated with simple Shiga-Kruse, Flexner, etc., mono-vaccines. Typhoid, paratyphoid A and paratyphoid B agglutinins, on the other hand, are produced in fair amount, though as a rule distinctly less than in control individuals inoculated with simple typhoid, paratyphoid A and paratyphoid B vaccines.

CONCLUSIONS.

1. A dysentery vaccine should contain several species of dysentery bacteria, and not one only.

2. As I have stated in all my publications since 1904, the vaccine should never be prepared with broth cultures, as such vaccine often gives a most serious reaction with very severe infiltration and occasionally an abscess.

3. The vaccine should be prepared with a carbolic salt emulsion from agar cultures without heating, or peptone-water cultures may be used. Of sensitized dysentery vaccines I have little experience.

4. It is essential to prepare the vaccine with strains which, though rich in antigen, are not virulent, or very little so. It is very rare to come across such a strain of the Shiga-Kruse germ. A large series of strains of this organism should be inoculated in rabbits, and the least virulent, provided it be rich in antigen, should be kept permanently as a stock culture to prepare the vaccine.

THE DIAGNOSIS OF ABORTIVE CEREBRO-SPINAL MENINGITIS.

BY

M. CULPIN, M.B., F.R.C.S., CAPTAIN (TEMP.) R.A.M.C.,
SURGICAL SPECIALIST, ALEXANDRA HOSPITAL, COSHAM.

ABORTIVE cases of cerebro-spinal meningitis are mentioned in the textbooks, but it is probable that many are overlooked by those whose mental picture of the disease is formed by their experience of the severe type.

In this district last winter the writer was able to

CHART A.—Patient reported sick with headache on the two days previous to admission. Puncture fluid contained diplococci and a few lymphocytes.

observe a series of cases ranging from the fulminant (proving fatal within twenty-four hours) to the mildest type where recovery is apparently complete by the end of a similar period. Though the mild cases form a series continuous with the severe, yet, as the disease assumes a benign form, a certain sign appears which seems of diagnostic value.

This mild or abortive type starts with a headache and evanescent meningeal irritation, as shown by a stiff neck

CHART B.—Igor two days before admission. Pains in head and neck. Face flushed and Kernig's sign present. Puncture fluid apparently normal. Herpes on lips twelve days after onset.

and Kernig's sign. Lumbar puncture at this stage may reveal a few pus cells (chiefly lymphocytes as opposed to the polymorphonuclear cells in the severe cases) and an occasional diplococcus, or may be negative. There is a rise of temperature, to which the pulse-rate is often unrelated, but within two or three days or even less the temperature and pulse become normal and the patient seems well.

If, however, a careful watch is kept the pulse-rate will be found to drop at some time between the second and seventh day after the onset. This drop may be to as low as 60 a minute and often as low as 50, and lasts a variable time, from a few readings only up to a week, with occasional increases. If the patient is allowed up whilst the pulse is slow, he complains of feeling poorly or "fuzzy in the head," and the pulse-rate does not increase.

This sign was almost invariably present in the cases in which there were clinical grounds for the diagnosis, even when lumbar puncture gave a clear fluid.

Slowing of the pulse is said to occur during convalescence from febrile illnesses, but such a slowing as is shown on the accompanying charts seems characteristic of recovery from a mild cerebro-spinal meningitis, and should be useful confirmation of a doubtful diagnosis.

An interesting case occurred in a ward orderly. He reported sick; his pulse-rate was 56; he had no headache, but volunteered a history of a bad headache three days before. His pulse remained slow for a week, and made occasional excursions to or below 60 in the week following, finally reaching his normal rate of about 80. It is probable that other signs would have been found if he had reported sick with his headache. Another man (Chart A) had reported sick on two successive mornings with headache. His medical officer then met the writer, heard his views, and mentioned the case. The man was sent to hospital, and lymphocytes and diplococci were found in his spinal fluid.

CHART C.—Onset day before admission; vomiting and headache. Face flushed; one purpuric spot on his back. Kernig's sign marked. Spinal fluid under pressure; watery, but contained diplococci. Labial herpes three days after onset.

The number of mild cases seen cannot be given, for some were certainly missed early in the epidemic, and there is no definite demarcation from the severe, but one may say that about twelve were recognized which the ordinary observer would not have believed to be a form of meningitis. They seemed commoner at the end of the epidemic, but that may have been because they were more often detected.

It is the opinion of the writer that many escape diagnosis, and it is necessary for the study of the disease

CHART D.—Onset three days before admission. Headache, stiff neck, and Kernig's sign. Puncture fluid apparently normal.

that they should be detected; it is for this reason that these observations are placed on record to be confirmed or confuted.

I have to thank Captain Leon, R.A.M.C.(T), for the bacteriological work in connexion with the whole series of cases.

THE seventh Pan-American Medical Congress, recently held at San Francisco, passed resolutions calling for the appointment by the various American Governments of a Commission for the systematic investigation of the medicinal flora of America. The view was expressed that this investigation should be conducted in connexion with recognized universities, hospitals and laboratories in the various countries, and in the instance of each article investigated should embrace: (1) A description of the plant; (2) its botanical classification; (3) its habitat, including the possibility of acclimatization and cultivating; (4) methods of gathering and transportation; (5) alkaloidal and other chemical properties; (6) present uses, domestic and professional; (7) pharmacological investigation, with experimental and subsequent clinical data; (8) the probable value of the plant as an article of commerce; (9) additional facts of value as may be demanded by the Commission or determined by individual investigators.

Reports of Societies.

FEMALE NURSES IN MALE WARDS OF MENTAL HOSPITALS.

At a meeting of the Medico-Psychological Association in London on February 17th Dr. GEORGE M. ROBERTSON, physician-superintendent of the Royal Edinburgh Asylum, Morningside, and lecturer on mental diseases in the University of Edinburgh, read a paper on the employment of female nurses in the male wards of mental hospitals in Scotland. After recalling that he had opened a discussion on the subject at the annual meeting of the association ten years ago, and observing that the shortage of male attendants in asylums had again made the consideration of the plan urgent, he gave a historical sketch of the growth of opinion on the subject. Auxiliary female care had been introduced into the Gloucester Asylum in 1841 by Dr. Samuel Hitch, who employed the wives of his married charge attendants to help their husbands. In 1883 Dr. R. M. Bucke, of the London Asylum in Canada, had employed widows in the male wards with complete success. Sir Thomas Clouston, who had placed a married couple in charge of the Male Hospital at Morningside, when the husband died in 1890 appointed the widow in full charge, and placed the male attendants under her authority. The defect of the system of auxiliary female care was that the nurses were few in number, and only assisted the male attendants, the bulk of the nursing even in those wards in which they were employed being still done by the male attendants.

The first step towards the system by which a group of male patients was entirely nursed by women was taken by Dr. Turnbull in the Fife and Kinross Asylum in 1896; he placed a ward containing thirty male hospital patients entirely under the charge of female nurses by day. Supervision was exercised by the matron and the charge nurse of the female hospital. The Scottish Commissioners realized the value of Dr. Turnbull's innovation, and on the advice of Sir John Sibbald a similar arrangement was introduced into the Glasgow (Gartloch), Lanark, and Perth District Asylums. In 1900, Dr. Robertson said, he had placed a group of male patients at the Stirling District Asylum under the charge of female nurses by night as well as by day. The Scottish system of entire female nursing was totally different in practice from that of auxiliary female care, and all who had large experience of women nurses in male wards agreed that they were infinitely more useful if placed in sole charge of a group, and they much preferred it themselves. The desire to make use in asylums of the high standard of skill in nursing possessed by those trained in general hospitals had led to the appointment of large numbers of trained hospital nurses during the last twelve years to important positions in the Scottish asylums; for, unfortunately, men did not receive training in nursing in the general hospitals. Dr. Campbell Clark was the first to appoint, at the Kirklands Asylum, Bothwell, in 1880, a trained hospital nurse to be matron. In the following year he began the systematic teaching and training of his asylum nurses and attendants. In 1885 the Scottish division of the Medico-Psychological Association published a handbook for attendants on the insane, which was subsequently adopted by the association, and had led to the granting of the certificate for proficiency in mental nursing and to the registration of certificated mental nurses.

The first hospital nurse to work within the wards among insane patients and asylum nurses was appointed by the speaker at the Perth District Asylum in 1896. This step not only had its direct influence on ward work, but created a supply of hospital nurses specially trained for the duties of asylum matronship. So great did the demand become that three dozen of his own nurses had received such appointments in other institutions. Nurses accustomed to attend to male patients in the general hospitals thought it the most natural thing to continue to take charge of male patients in asylums, and their presence had led to the introduction of innumerable reforms which had approximated the methods employed in the asylums to those in the hospitals, and the greater employment of women in the male wards was only one among these. The employ-

ment of female nurses in the male wards in Scotland was, in fact, only a part of a much greater ideal—that of the hospitalization of the asylum. Nursing by women was now as distinctive and firmly established a feature of the Scottish system of care for the insane as the boarding-out system. It was employed in some measure in all but two of the important asylums of the country, and in these exceptions failure to introduce it was not due to opposition to the principle but to structural difficulties. In a fourth of the asylums in Scotland, and among them some of the large ones, the matron was head of the staff on the male side as well as on the female side.

In introducing female nurses into the male wards for the first time the most reliable women on the staff should be selected. They should be experienced and should not be young. The working unit should not be less than four, and it was a great advantage to place a hospital nurse with asylum experience in charge of them. They were best adapted to manage wards containing patients confined to bed. When the patients were dressed and going about it was advisable to employ one or two trustworthy male married attendants to bathe the patients and to assist in other ways. It was not true that female nurses were only of use in the care of the sick and helpless in an asylum. They usually exercised more control over cases of mania than male attendants, and their success was due to the fact that their method was based on persuasion and not on force or compulsion. A woman had much the same influence over an insane man not actually delirious as she had over one supposed to be in his sound mind, and it was absurd to assume that all feelings of chivalry and honour died in a man because he suffered from some derangement of the mind.

The capacity of the insane for education in good habits, while not illimitable, was very extensive, and in practice was never exhausted in large institutions. If it could be alleged of any asylum that its male wards were not a suitable place for women, then the sooner a reformation was effected the better, for it was not a condition that need continue indefinitely. Male patients were always less troublesome and excitable than female, and women found that they received more courtesy and readier obedience from men than from women. It was not necessary to pay an extra salary, for once the system was started the women were engaged as in general hospitals, simply to nurse, and it was all in the day's work whether their patients were male or female. It was doubtful whether the employment of women instead of men would mean any saving in expense, because, owing to the higher standard of hospital care sought, usually a larger number of nurses was required. In Scotland any saving had been more than counterbalanced by the increased night staff, which was proportionally much larger than that employed in English asylums and on hospital nurses for purposes of supervision, a practice now largely adopted. Lastly, it has been said that many male patients, owing to their sexual proclivities, could not be cared for by women. This was undoubtedly true, but the remedy was simple—do not place them under women; let them be cared for by men. No experienced administrator would allow a simple difficulty of this kind, with an obvious remedy, to deter him from the introduction of women nurses. Every day of the year, in every asylum in the country, a much more difficult and responsible task of an analogous nature was faithfully performed—that of distinguishing the patients who were suicidal from those who were not, and of making special arrangements for their care. To pick out patients whom it was undesirable to place under the care of women was, compared with this, an exceedingly simple matter.

Nursing the sick, the infirm, and the helpless, sane or insane, was pre-eminently woman's avocation, and Sir Thomas Clouston had summed up the situation tersely when he said that all his nurses longed to work in the hospital, whereas all his male attendants preferred outdoor work. Moreover, women were better than men at the superintendence and discharge of domestic duties. The proportion of women it was desirable to employ on the male side of an asylum was, according to the Scottish Board of Control, at least 25 per cent. of the total day staff on the male side and 15 per cent. of the night staff. These figures were considerably exceeded in several asylums, among which might be mentioned the Stirling District Asylum. It might be taken as a typical county

asylum in the accommodation it provided, in its complete organization, and in the modern methods it employed. It admitted over 250 patients annually, and had a resident population of over 800. Dr. R. B. Campbell, its medical superintendent, had employed for the last seven and a half years, as the speaker did for an equal period, a staff on the male side by day of which 40 per cent. consisted of women, there being three hospital nurses, including the matron. By night 27 per cent. of the staff consisted of women, including the night superintendent, who is a trained hospital nurse.

Dr. Robertson said that he did not accept the contention that female nurses were more suitable for asylums admitting parochial than for those receiving private patients. Craig House, the department of the Royal Edinburgh Asylum for private patients, was a separate mental hospital, and of the staff of 32 employed by day to attend to 100 gentlemen exactly one-half consisted of nurses, including in this number the lady superintendent and 3 matrons, and of these 3 were hospital nurses. At night 6 out of a staff of 13 consisted of women, including the night superintendent, who was a trained hospital nurse. The proportion of women varied, and had perhaps been swelled by the war, but there was no difficulty in employing 40 per cent. of women by day and 25 per cent. by night in a private asylum.

In the discussion which followed some criticism was heard, but on the whole a striking amount of agreement with Dr. Robertson's contention. Dr. STODDART said that the employment of male nurses in male wards was an anachronism, but he would prefer women nurses who possessed the association's special certificate as mental nurses, for they would be superior to ordinary hospital-trained nurses for the work. Dr. WOLSELEY LEWIS agreed; he was not in favour of hospital-trained nurses, as the conditions were very different in asylums. Dr. SOUTAR, while thinking that male attendants should not be employed in hospital duties, had not found them so deficient in the capacity to nurse as to feel justified in ousting them. Sufficient importance did not seem to have been attached to the fact that in asylums physically fit patients rendered various kinds of assistance. Dr. SARGENT, after trying a wholly male staff, and finding it a failure, had, after a short period of partial employment of females, appointed a wholly female staff. Dr. LEGGE, from a careful study of the Scottish system at the time when his committee decided to build a new asylum, had become convinced that the system advocated by Dr. Robertson was much ahead of the general system used in England. In the Derby asylum 90 per cent. of the patients were put straight into the wards and nursed by women both by day and night. Dr. BRANDER said that he had found male patients objected to being nursed by women, and in any case disapproved of the employment of mixed staffs. Dr. HAYES NEWINGTON thought it would be dangerous to accept the principle that women were essential as nurses on the male side, although he recognized that female influence was very useful on that side. Ambulatory male patients should not be placed solely in the charge of women. Dr. O'NEILL considered that it was essential at first to have hospital-trained nurses to instruct beginners in the proper conduct of a ward. In seven years' experience of female nurses for male patients he had not met with difficulties, nor had he seen any evidence of depreciation of the moral tone of the nurses. The President Lieutenant-Colonel DAVID G. THOMSON, M.D., considered that the plea for female nursing of male patients was sound within very definite limitations. It was not possible to make the case of the asylum precisely parallel to that of a hospital.

BOTHRIOCEPHALUS LATUS.

At the meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on January 21st Dr. T. T. O'FARRELL showed a specimen of *Bothriocephalus latus*, believed to be the first detected in Ireland. It had been supplied to him by the Right Hon. M. F. Cox, M.D. The patient, a man who resided on the banks of the River Shannon, in co. Longford, had suffered for some time from vague symptoms of indigestion, but had no pronounced anaemia. He passed the first segments of tapeworm in December, 1915. The usual antichelmintics were given.

The head had not been found, but the smallest segments had been recovered. The man had always resided in Ireland, except for three trips to England and two to Scotland, each of about five or six days' duration. On these occasions he did not partake of fish. He had frequently eaten fish from the Shannon—perch, pike, bream, roach, and eels—but no trout so far as he remembered. The fish had not been undercooked, and others had eaten of it without becoming infected. [It may be added that the ordinary host is the pike, and that Leuckart does not mention the trout.]

Reviews.

VAGOTONY.

THE vagus nerve, like the nerves of the somatic system or sensorimotor nerves, is constantly transmitting tonic impulses to the viscera it serves—namely, the heart, bronchi, oesophagus, stomach, intestine, and pancreas. In a general way, it may be said that the drugs pilocarpin, physostigmin, and muscarin increase the force of these tonic impulses, while atropin depresses them and tends to produce vagal paralysis. Drs. EPPINGER and HESS¹ have endeavoured to isolate from the mass of nervous disorders known as the neuroses a group of patients in whom the neurosis is due to abnormally great tonus of some of the involuntary muscles or secreting tissues supplied by the vagus nerve, and have published their results in a pamphlet of which Drs. Kraus and Jelliffe have recently issued an English translation. Such a vagotonic patient, it is stated, is abnormally sensitive to the subcutaneous injection of pilocarpin; the dose of 1 cg. ($\frac{1}{2}$ grain), producing sweating and salivation, and such other signs as hyperacidity, eosinophilia, asthma, slow pulse and respiratory or cardiac arrhythmia, and spastic constipation. If the case is one of vagotony, these signs and symptoms will be relieved by the exhibition of atropin.

Vagotonic patients are said to exhibit a rapid and forcible ("nervous") action of the heart when the precordia are inspected. Gastric hypersecretion and hyperacidity, and their extreme form gastrouscorrhoea or Reichmann's disease, with pylorospasm and increased peristalsis and antiperistalsis, and cardiospasm and oesophagospasm, are all common in vagotony and may habitually be relieved by giving atropin. Vagotony may produce either constipation or diarrhoea, by increased intestinal peristalsis or by intestinal spasm; the authors believe that some cases of spasm of the gall bladder and bile ducts are due to vagotony without local organic disease. Finally, they mention eosinophilia as developed on a vagotonic basis; it may be evoked by pilocarpin and dissipated by atropin, and is entirely lacking in patients with the opposite condition of sympathicotony or abnormal tonus of the muscles and glands mainly innervated by the sympathetic nervous system. The skin of vagotonic patients flushes easily and perspires freely; the patients are thin (this is a great fault in Vienna) but have large, often beautiful eyes which glisten; the heart is excitable, the reflexes are very brisk, the urine is often hyperacid, gastric and intestinal derangements are common. Persistence of the thymus and the lymphatic constitution are not rare; indeed, vagotony is summed up as a form of constitutional inferiority. It will be seen from this brief and incomplete review that the authors make the conception of vagotony cover a very wide clinical field; with what success is a question that the future will decide. Many of the authors' far-reaching conclusions seem to be based on deductions drawn from only a case or two, and to be quite unwarrantable as generalizations. They do not appear to state the doses of atropin required to relieve the main symptoms of vagotony.

The translators have done their work fairly well; a note should be added on p. 4 to the effect that in English-speaking countries the autonomic nervous system—a term introduced by Langley in 1898—means the nervous system of the glands and of the involuntary muscles, and includes

¹ *Vagotonia: A Clinical Study in Vegetable Neurology*. By Dr. H. Eppinger and Dr. L. Hess of Vienna. Authorized translation by Drs. W. Max Kraus, A.M., M.D., and Smith Ely Jelliffe, M.D., Ph.D. Nervous and Mental Diseases. Monograph Series, No. 20. New York: The Nervous and Mental Disease Publishing Co. 1915. (Roy. 8vo, pp. 93. 1 dol.)

the sympathetic nervous system. Drs. Eppinger and Hess describe Langley's "autonomic" as the "vegetative" nervous system, and divide the vegetative into the "sympathetic" and the "autonomic" nervous systems, thus perpetuating a very confusing and unnecessary difference in terminology.

PROGNOSIS.

We have formed a high opinion of the value of the *Index of Prognosis and End-results of Treatment*, edited by Dr. A. RENDLE SHORT,² which is issued as a companion to the *Index of Treatment* and the *Index of Differential Diagnosis*. As the title indicates, it aims particularly at setting forth the end-results of various methods of treatment, their advantages and their risks, while it also furnishes data for arriving at accurate forecasts of what will happen to an individual patient. Although we admit that there is justification for the claim that this volume stands by itself and that no modern work in the English language can compare with it, yet we do not agree with the complaint that little help in prognosis is given by current textbooks, which generally include prognosis in their descriptions of diseases, and although they do not always support their conclusions by "trustworthy figures," they do so in many instances—as, for example, in the treatment of typhoid fever, diphtheria, gastric ulcer, and of cerebro-spinal fever, to give only a few instances. It may be true that the published results of individual surgeons are often "touched with *couleur de rose*," but the compilers of textbooks are not open to this reproach, and such published figures have been subjected over and over again to analysis by hospital registrars and others, so that it is only the reports of a quite new method which may mislead by being unduly favourable; this must continue to be the case so long as enthusiasm for what is believed to be progress persists, and should it be lost we fear that with it would also disappear the ardour of mind that has brought about the real advances of the last fifty or sixty years.

We have carefully read many of the sections, and where all are good it may seem invidious to select any for special praise; yet we may mention those on angina pectoris, appendicitis, exophthalmic goitre, heart disease, tuberculosis of the genital and urinary organs, and diseases of the stomach. We repeat the favourable opinion with which we opened this notice, and desire to commend the work to our readers as one which they would do well to place upon their bookshelves.

HINDU THOUGHT.

In his work, *Indian Thought, Past and Present*,³ Mr. FRAZER has compiled an exhaustive treatise on a very abstruse and difficult subject. After an introductory chapter he first discusses the Vedas, "the dawn of thought," dating back to the first Aryan invasion of India, 2,000 to 1,500 B.C.; then he deals with the philosophic studies of the Brahmanas, and explains their view of the Pythagorean doctrine of transmigration. After next giving an account of the Upanishads, or books of secret knowledge, he describes in successive chapters various schools of thought—of Vedanta, the world as illusion, *maya*; Sankhya, the world as matter; Vaiseshika and Nyaya, the world as atoms; lastly, Yoga, or asceticism. The longest chapter—nearly half of the whole work—relates the rise, sway, and decline of Buddhism. In the next chapter, on (modern) Hinduism, the author discusses the proposal, now passed into an Act, for the institution of a Hindu University at Benares, with a faculty of Hindu theology; points out the similarity between the Biblical story of Christ and Herod and the Hindu legend of Krishna and Kans, and considers the possible Christian origin of the latter; he next compares the tenets and practice of the two chief Hindu cults—the worship of Vishnu the Preserver, and of Siva the Destroyer. The third member of the Hindu Trinity, Brahma, the Creator, has no extensive following; only

two temples in his honour exist in India. The next chapter deals with the past and present position of woman in India, while the last describes the Hindu thought of the present day, with the foundation of the Brahmo Samaj by Raja Ram Mohan Roy in 1828; and of the Arya Samaj by Dayananda Swami in 1875.

Perhaps "Hindu Thought" would have been a more accurate title than *Indian Thought*. Islam is barely mentioned. It may be said that all Indian thought is Hindu. The Musalman is usually a practical person, whose religious doctrines are crystallized in the *Quran*, and is little given to deep speculation, either philosophic or religious, yet between one-fourth and one-third of the population of India is Musalman, and many of the more virile races follow the creed of Muhammad. Very little also is said of Sikhism. Belief imported from abroad, the author considers, is foredoomed to failure. Buddhism, Islam, and Christianity have left Hinduism almost unaffected.

The author speaks of the "sting" of a snake (p. 232, last line). Snakes do not sting, they bite. Another slip occurs on p. 301, where it is said that the latest Marriage Act, the "Age of Consent" Act, was passed in 1891 by the Government of Lord Lawrence. This should be Lord Lansdowne. Lord Lawrence's viceroyalty was a quarter of a century earlier. The illustrations are well executed, and most of them are beautiful.

NOTES ON BOOKS.

IN his little book on *The Dietetic Treatment of Diabetes*⁴ Major BASU gives an account of the etiology and treatment of a disease that is, for one reason or another, very common in India. There is nothing very abstruse in the text, which draws its strength largely from quotations from the works of Pavy, von Noorden, and other standard authorities on diabetes mellitus. The book is designed for the use of the inhabitants of India, and it may be warmly recommended to their attention as a short and practical manual.

A brief and breezy account of the life spent by an Englishwoman nursing in a French military hospital is furnished by DOROTHY CATOR,⁵ who points her moral and adorns her tale by many incidents showing the vices and the virtues of both the French and the English. It seems that if the French have much to learn from us about the management of hospitals, we in turn may learn much from them as to the graces of life and daily dealings with one another. The authoress was shocked by the dirt and lack of religious principle she found in France; she is still more shocked by the national conceit and inability to learn that now, she fears, threaten to drive England definitively to the dogs. The book is good reading, and appeals to the layman rather than the medical practitioner.

*The Log of H.M.S. Bristol*⁶ seems to be exactly what it professes to be—namely, a diary kept by a leading signalman during the commission from May, 1914, to December, 1915. She was part of Admiral Sturdee's squadron at the Falkland Islands, but when the action began was detached with the *Macedonia* to sink two colliers, which they did, taking off 109 prisoners. Afterwards the *Bristol* took part in the four months' search for the *Dresden* in the Magellan Straits. This meant a great change of climate, for in the earlier part of her commission the *Bristol* was sent to keep an eye on the Mexican revolution, in which, at that time, the world was much interested. Unfortunately, the ship went aground in one of the narrow channels in the Straits, damaging her rudder so badly that another had to be extemporized under great difficulties. The account of the incident gives a good idea of the emergencies the engineering branch may have to face at any moment, and the skill and perseverance with which they are met. The book is well worth reading not only for the historical events in which the ship and the writer took part, but also because it gives a plain picture of life at sea during war, its long weeks of monotony and short hours of excitement.

⁴ *The Dietetic Treatment of Diabetes*. By B. D. Basu, Major I.M.S. (retired). Sixth edition, revised and enlarged. Bahadurganj, Allahabad: The Panini Office. 1915. (Cr. 8vo, pp. 108. Rs. 1.8.)

⁵ *In a French Military Hospital*. By Dorothy Cator. London: Longmans, Green, and Co. 1915. (Cr. 8vo, pp. 99. 2s. 6d. net.)

⁶ *The Log of H.M.S. Bristol*. By Wm. Huchan, Leading Signalman. London: The Westminster Press. 1916. (Cr. 8vo, pp. 163; illustrated. 4s. net.)

The *British Journal Photographic Almanac* for 1916, edited by Mr. G. E. BROWN, gives a summary of the recent progress of photography, and is an up-to-date guide in all photographic matters. It contains a compendium of practical hints gathered from British and foreign journals, and an excellent account of the various printing processes explained in such a way as to be intelligible to beginners. British firms are now thrown very much on their own resources in the manufacture and supply of photographic material of all sorts; indeed, some of these firms appear to have transferred their energies to the manufacture of munitions. There appears to be nothing of interest to skiagraphers in the *Almanac*, which came out first as long ago as 1860. It should be in the hands of every photographer, professional or amateur.

MEDICINAL AND DIETETIC PREPARATIONS.

A New Intestinal Antiseptic.

In a paper recently read to the members of a Connecticut medical society Dr. J. T. Ainslie Walker brought forward a new intestinal antiseptic which, he claims, is really effective. Countless excellent antiseptics have been employed in the past for the purpose of lessening the putrefactive processes that occur normally in the intestine, and when unduly free produce symptoms of disease. To mention only a few out of many, calomel, mercuric sulphide, salol, resorcin, various bismuth salts, beta-naphthol, and naphthalene tetrachloride have all had their vogue as intestinal antiseptics, and all have proved failures in the hands of the great majority of medical practitioners. As a result of this we have seen other methods of lessening intestinal sepsis recommended and practised, notably the use of the lactic acid bacillus advocated by Metchnikoff and the more drastic surgical procedures of Sir Arbuthnot Lane. The new drug so strongly recommended as an intestinal disinfectant by Dr. Walker is a benzene derivative, 1-2-4-5-6-trimethylmethoxyphenol, with the formula $C_6H_3(CH_3)_3(OCH_3)OH$. He does not mention how it is formed or where it may be obtained. It is administered by the mouth in the form of 2½ minim gelatine capsules containing a 50 per cent. admixture of the drug with a vegetable base, and alternatively as a syrup, for infants and children unable to take the capsules. A 50 per cent. gelatine emulsion of the drug is known for short as "trimethol." It is stated to have a Rideal-Walker coefficient of 20, or in other words to be twenty times more efficient than pure phenol as a germicide, and is not, it is said, decomposed in its passage through the alimentary tract, and is excreted unchanged in the faeces. It appears from the cases quoted by Dr. Walker that up to twenty of the capsules of trimethol described above may be given to an adult daily; offensive diarrhoea, enteritis, ulcerative enteritis, mucous colitis, and ulcerative non-amoebic dysentery are mentioned among the intestinal disorders in which the new drug proved strikingly effective. As every medical man knows, intestinal sepsis is nowadays credited with being the *fons et origo* of many diseases that may at first sight appear to have little connexion with it—rheumatoid arthritis, for example, and pernicious anaemia. Dr. Walker certainly makes out a good case for the further trial of trimethol in both acute and chronic septic disorders of the intestine.

ROYAL MEDICAL BENEVOLENT FUND GUILD.

ANNUAL GENERAL MEETING.

The annual general meeting of the Royal Medical Benevolent Fund Guild was held at the Mansion House, London, on February 21st, the Lord Mayor (Sir Charles Wakefield) presiding. Lady TWEEDY read the report of the council, in which reference was made to the success of the sale of work at Crewe House last November, by which more than £1,000 was added to the funds of the Guild. During the year written reports had been made upon 400 cases—a "case" often meaning a family—which had been referred by the Fund to the Guild. Mrs. LIVING, in an account of the work of the Visiting Committee, mentioned that as a result of the war the Guild was called upon to deal with many widows and children who, in happier times, would never have dreamed of asking for such assistance. Mrs. SCHARLIEB made the

treasurer's statement, from which it appeared that the income of the Guild during the year, including the proceeds of the Crewe sale, was £3,726; £1,500 of New Zealand stock had been purchased, and the special education fund now stood at £300.

Sir ARTHUR MAY, K.C.B., Medical Director-General, said that when the war was over it was possible that the outlook for benevolent organizations would not be so black as some were inclined to depict it. Many a wall of prejudice would have been broken down, and charity would have a wider gate. The Guild stood especially to benefit from the new social impulse, for the public support would be given to those societies which had under their care cases of distress arising directly out of the sacrifice of the individual in the war. Speaking for his own branch of the service, he said that the navy was at concert pitch, and to this state of affairs, which was a matter less of material than of personnel, the medical department had very largely contributed. Notwithstanding the hardships of the long vigil, the health of the fleet to-day was better than it had ever been since statistics were taken. At least half the medical men now serving in the navy had left civilian practice during the last eighteen months. No profession stood to lose so much by service with the forces as did the medical profession, simply because it was a profession which depended to so great an extent upon personality. Patients were notoriously fickle, and it was possible that by the time the doctor returned to civil life he would have to rebuild his practice almost from the beginning. Time after time since the war began he had been approached by medical men, who had said, "I would join to-morrow if it were not for my wife and children." In such cases he used no pressure, but many men had left family and practice to come and do their share. Before the war the insufficiency of medical men in the navy had been a great shadow upon his mind, but it had been lifted by the splendid manner in which civilian doctors had come forward. They were serving to-day in every theatre of war, and it was for those who remained at home to do their utmost to relieve from possibility of want the dependants of these men should the breadwinner be called upon to make the final sacrifice.

Dr. JAMES CAMPBELL McCURE said that medical men were not much given to looking to the morrow, partly because the temperament which led a man to the medical profession was the reverse of that which tempted a man to business, and partly because the training of the medical student encouraged on the one hand a scientific abstraction and on the other an altruistic spirit. This temperament and training, combined with many social demands made upon the young doctor, furnished the necessity for the Fund and Guild. The world was often surprised to find how little a doctor had bequeathed, forgetting that the few years of prosperity which had preceded his death had been spent only too often in the liquidation of debts incurred during his years of struggle. Dr. McCURE suggested that appeals for this benevolence should have a place in every hospital and college; and Dr. LOUISA GARRETT ANDERSON, in a later speech, made the further suggestion that grateful patients should be asked to help by a donation, instead of offering the silver tankard or cigarette case which sometimes figured as a personal gift to the family doctor.

On the motion of Sir WILLIAM CHURCH a vote of thanks was accorded to the Press, more especially the medical Press, for space granted to the work of the Guild, and the meeting closed with compliments to the Lord Mayor and Lady Mayoress voiced by ADELIN, DUCHESS OF BEDFORD, and Sir JOHN TWEEDY.

THE Secretary of the London (Royal Free Hospital) School of Medicine for Women has forwarded to us a prospectus explaining the arrangements for dental students. The Royal Dental Hospital of London School of Dental Surgery, Leicester Square, and the University College Hospital dental department and school (National Dental Hospital) are both open to women students. That part of the course only which is not obtainable at the dental school and hospital is taken at the Royal Free Hospital school. The prospectus explains the course of study, which occupies a minimum period of four years subsequent to registration, and includes three examinations.

British Medical Journal.

SATURDAY, FEBRUARY 26TH, 1916.

SIR WILLIAM TURNER.

SIR WILLIAM TURNER throughout an active life which exceeded the common span exerted a great but often silent and unseen influence on the development of medicine in this country. His influence was due in part to a strong intellect, in part to his own example of diligence and continuity in scientific research, and in still larger part perhaps to a staunchness of character which made it impossible to imagine that he could ever be blown about by any wind of doctrine.

For more than sixty years he was actively concerned with medical education. For almost half a century he taught anatomy in the University of Edinburgh, and how great he was as a teacher is shown by the list of his pupils who are now teaching anatomy all over Greater Britain. All that time he had been impressing his ideals and his character not only on his pupils, but on the whole of that great university, until, when he was 71, he was called to be its chief executive officer. As was characteristic of him, he had long before this made himself thoroughly acquainted with the business of the university in all its aspects, and by so doing had incidentally broadened his own outlook on medical education. It was in the fitness of things that the university should have sent him quite early to represent it on the General Medical Council, and that that body after experience of his qualities should have chosen him to be its President. As Sir Donald MacAlister says in the tribute he pays to his predecessor elsewhere in this issue, Sir William Turner had to face a somewhat difficult position. Things were going askew with the Council in more than one respect, and there was not wanting much depreciatory and destructive criticism. Turner met it not by retorting, but by quietly and steadily setting to work to right what was wrong. He succeeded by being just and constant, keeping an open mind, and not letting prejudice imported on either side bias his judgement; he had, as his successor says, the judicial mind, and that perhaps sums up his outstanding quality as no other phrase could.

To his scientific work he brought this same quality of mind and with the like success. No doubt his appointment in the prime of early middle life to the chair of human anatomy in Edinburgh gave him a very great opportunity—there was no like opportunity in Great Britain at that day—but his was the merit of taking full advantage of it and realizing fully how it was to be used. It was a moment when the science of human anatomy needed a leader of the comprehensive and accurate mind and breadth of outlook which Turner pre-eminently possessed. The enthusiasm that had impelled and sustained the older students of human anatomy was dying away: their method had been worked dry to the dregs. Two new currents of thought were beginning to flow. Harvey, first of the great British anatomists, and, after a long interval, Bell, had shown the course along which one stream was to run—the application of experiment to anatomy, hitherto a science of pure

observation. Its course had then already brought it close to physiology, and now no clear line can be drawn between the two. The other current was towards comparative anatomy and anthropology—to the study of man's relation to the rest of the animal world, to his ancestors, and of races to each other. Both currents combined to carry human anatomy into the broad stream of biology. It was to the second stream that Turner committed himself and most of his original work; without detracting from his contributions to comparative anatomy it may be said that it was in anthropology that his work and his influence was most fruitful. To the influence of his teaching is largely due the eminent position of British anthropology—its richness in detail, grasp of principles and boldness in speculation, qualities in which its only rival is the French school. We are fortunate to be able to publish this week a tribute by Professor Arthur Keith which deserves that much abused epithet "eloquent." The facts are eloquent in themselves, and the truth of his summing up will, we believe, be more and more appreciated: that "the most marvellous aspect of the whole" of Sir William Turner's "career was his ability to combine a life of extraordinary scientific industry with one laden with administrative duties."

PENSIONS AND ALLOWANCES ON DISABLEMENT BY DISEASE.

MANY instances have been brought to public notice of soldiers and sailors who have been discharged from the army or navy on account of constitutional weakness, without prospect of pension or other national recognition of the services that they may have rendered. The whole question of the responsibility of the State for the future care of its defenders of all ranks was brought prominently forward by an amendment to the Address moved by Mr. W. Thorne in the House of Commons on February 16th to the effect that the Government should accept responsibility for the payment of pensions and allowances to all soldiers and sailors discharged on account of diseases contracted or developed during service with the colours. In his brief speech the mover asserted that it had been stated that it was not possible to pay pensions to soldiers or sailors discharged for medical defects. He questioned the right of the Government to refuse such pensions, and maintained that a recruit, once passed as medically fit and accepted for service, should, even if serving only for home defence, be entitled to the same treatment as the wounded man from the front, if he should be incapacitated by disease.

The debate served to emphasize the strong feeling which animates both public and official circles that the spectacle shall not again be permitted of the disabled defenders of their country reduced to poverty and want. The action of the War Office and the Admiralty has hitherto been guided by the terms of a Royal Warrant and of an Order in Council, and these terms admit of varied interpretation. The parliamentary representatives of both services expressed the earnest desire to interpret them sympathetically, but at the same time indicated that discretion must also be regarded.

Breakdown in health from constitutional causes, such as a tendency to rheumatism or tuberculosis, may occur in military as well as in civil practice, and it is equally difficult, if not impossible in many cases, for medical authority to forecast the liability to such breakdown.

More especially is this the case with regard to tuberculosis. Many members of Parliament would still seem to have overlooked the fact that a large proportion of the population become infected, at some period of childhood or adolescence, with tuberculosis. The most careful and prolonged medical examination may fail to detect evidence of the latent disease, although it may at any time become active. It does so far more frequently in the person of the sedentary clerk in his office than in that of the similar individual transferred to the active open-air life of the camp. The hardships and dangers of life under fire have undoubtedly been followed in some instances by a recrudescence of tubercle, countless examples have been forthcoming of the invigorating effect of the strenuous open-air life upon young men of slender physique who have been thereby converted into hardy soldiers. A large proportion of such men must be potentially tuberculous, but it is wholly beyond the powers of medical boards, however carefully constituted, to say whether such potentiality will ever become active.

The establishment of a statutory committee to make provision for the care of disabled officers and men after they have left the service will doubtless provide a court of appeal in difficult cases, but it is not to commence operations until next July. In the meantime the National Relief Fund and the Soldiers' and Sailors' Families Association are available to deal with urgent cases.

It was made quite clear in the course of the debate that, while the terms under which pensions and allowances are granted must be adhered to, they will be liberally interpreted, but such liberality will not extend to the cases, of which there must of necessity be a certain proportion, in which the breakdown occurs within a short time after enlistment. Medical boards, often working at high pressure to examine recruits, are not infallible, and the principle that the Government must make itself responsible for the future care of every one who passes the doctor is too sweeping for acceptance. Many of the speakers were inclined to adopt the interpretation of the Workmen's Compensation Act as defining the liabilities of the Government with respect to pensions and allowances, but the general outcome of the discussion upon the amendment, which was withdrawn, did not indicate more than a general desire on the part of the speakers for sympathetic treatment of hard cases, and a willingness on the part of the Government to accord it.

ARMLETS AND ATTESTATION.

The attention of all medical men who are single and under the age of 41 next birthday, and who are enrolled with the Central Medical War Committee, is called to the fact that they can only obtain armlets under the Derby scheme if they are attested. The period for attesting terminates automatically when the provisions of the Military Service Act come into force on Thursday next, March 2nd. It is important, therefore, that every medical man to whom the above description applies, and who wishes to be in a position to wear an armlet, should make arrangements to attest within the next few days. Attestation, with the consequent right to wear the armlet, will make it clear that the wearer has, while the voluntary system is still in force, shown his readiness to serve his country when called upon to do so.

MEDICAL STUDENTS AND THE MILITARY SERVICE ACT.

In consequence of the passing of the Military Service Act, 1916, the Army Council has issued an instruction modifying the procedure to be followed in the case of medical students

as provided under the Derby scheme.¹ The instruction will be distributed in recruiting subareas, and directs that all medical students in their fourth or fifth year of study, and those in their third year of study whose examination takes place during the winter session, must either attest under the group system or become liable to the Military Service Act. A student who attests under the group system should produce a certificate signed by the dean of the faculty of his college, to the effect that he is enrolled in an officers' training corps, and is either a fourth or fifth year student, or a third year student to be examined during the winter session. A fourth or fifth year student will not be called upon, while a third year student will be postponed to April 15th, 1916. In their case, recruiting officers on that date are instructed to ask the dean of the college concerning the result of the examination. If the student has passed he will not be called up; if he has failed he will be called up, provided the group to which he belongs has been called up. A student who does not attest under this, the voluntary, system becomes liable to the provisions of the Military Service Act, and must appeal to the local tribunal if he desires exemption. A certificate from the dean of the faculty of his college stating that he is enrolled in an officers' training corps, whether he is a third, fourth, or fifth year student, and if a third year student that he is to be examined during the winter session, must be attached to the claim, and military representatives are instructed to assent to such claims subject to the provision, in the case of the third year's student, as to the examination being passed during the winter session. On April 15th the military representatives will apply for the withdrawal of the exemption certificates of third year students who have failed in their examination. The order is dated February 20th, 1916 (No. 389, Military Service Act).

MEDICAL EXAMINATION OF ENROLLED MEDICAL MEN.

The following is the text of an instruction which is being addressed to the Deputy Directors of Medical Services in Commands: "In connexion with the question of the enrolment of medical men for service with the army, it has been decided that local arrangements shall be made for the physical examination of all medical men who are so enrolled. The Central Medical War Committee have accordingly been instructed that they, or the local committees, may arrange direct with you for the examinations to be carried out at the nearest recruiting board. Each candidate should be required to complete Army Form W. 3075, and in case of unfitness the reasons should be stated on the certificates. When the cause of unfitness is defective vision, the degree of vision with and without glasses should be stated. The certificate and Army Form W. 3075 should be returned to the local committee, and will be forwarded by them to the Central Medical War Committee or Scottish Medical War Emergency Committee, who in turn will send these documents to the office."

CEREBRO-SPINAL FEVER IN 1915.

ACTING in collaboration with the War Office, the Medical Research Committee has recently issued a full and interesting report² upon the bacteriological studies of cerebro-spinal fever made by a number of specially competent observers at twenty-four separate stations in England during the first eight months of the year 1915. The report is divided into five parts. The first of these is concerned with the biological properties of the meningo-

¹ SUPPLEMENT TO BRITISH MEDICAL JOURNAL, January 15th, 1916, page 9.

² Report of the Special Advisory Committee upon Bacteriological Studies of Cerebro-spinal Fever during the Epidemic of 1915. Medical Research Committee, London, 1916. (6d.)

coccus, the organism still accepted by practically all bacteriologists, as the report states, as the infecting agent in cerebro-spinal meningitis. Discussing the evidence adduced by Dr. Hort and his collaborators¹ to show that Weichselbaum's meningococcus is a highly pleomorphic organism—perhaps a "late non-infective phase" of a microbe which may be a filter passer—the authors of the report do not agree with any such views; they characterize the "pleomorphism" rather as "involution." They make many interesting observations on the difficulties of identifying the meningococcus, due in part to the fact that it exists in many different immunological strains or races, or even in forms so different from one another as to deserve the name "subspecies." No finality has been reached as yet in this matter; in the same way no finality has yet been reached in the formula of the culture medium best suited for the rapid isolation or identification of the meningococcus. At the present time a pea-flour-agar medium, known as "tryptagar," is probably the best for this purpose, though it leaves much to be desired. It is noted that nasal mucus, saliva, and other organisms such as pneumococci and streptococci, all tend to inhibit the growth of meningococci on culture media, an obvious further embarrassment in the search for the microbe on swabs from the nose or throat. Regarding the bacteriological diagnosis of cerebro-spinal fever, the report speaks of the invariable presence of polymorphonuclear leucocytes in the cerebro-spinal fluid during the active stages of the disease, and emphasizes the fact that they make their appearance here very early in the disease. This is of interest as not being in accord with the early cerebro-spinal lymphocytosis described by Netter, Sophian, and others, as of frequent occurrence. It is noted that the meningococcus can be grown from the circulating blood in only a small proportion of the cases, and those the most acute; yet the authors of the report believe that the route of infection in cerebro-spinal meningitis is habitually from the pharynx to the meninges by way of the blood stream. They hold that it is but rarely excreted by the kidneys. Part III of the report is given to an analysis of the very extensive investigations of the problems raised by meningococcus carriers that have been made. Roughly speaking, 6 or 7 per cent. of carriers were found in a total of over 10,600 contacts examined, the percentages found by different observers varying from 1 to 20. As regards treatment, the general conclusion reached is that the meningococcus carrier will recover spontaneously almost as fast as with the most careful local or general treatment; vigorous local treatment is certainly undesirable. In Part IV the epidemiology of the disease is discussed from the bacteriological point of view; overcrowding and deficient ventilation are described as the chief factors in the spread of cerebro-spinal fever among soldiers. The incubation period is indefinite, varying from three days to three weeks and probably longer. The authors regard the meningococcus as essentially a saprophyte with a low virulence for the average human being, excluding infants; in times of epidemic cerebro-spinal fever individual races of meningococci must be assumed to attain a greater virulence that enables them to produce meningitis in young adults who in ordinary circumstances are immune. There is evidence to show that at least one of the three principal meningococcal strains concerned in last year's epidemic was introduced by the Canadian troops. Part V of the report deals with the specific treatment of the disease, the results of which have certainly been disappointing. The reason for this no doubt lies in the multiplicity of the meningococcal strains that are abroad among us. The use of hexamine and soamin has been no more successful. This report is one that should be read by all who wish to keep abreast of our knowledge of cerebro-spinal fever.

EUGENICS AND THE WAR.

EUGENISTS who had been anticipating some speculations on the effect of the war on the race were a trifle disappointed with Professor E. B. Poulton's Galton lecture delivered last week. His subject was "Eugenic Problems after the War," but he seemed to feel, with the Walrus, that the time had come to talk of many things, and after touching on the revolting eugenic effect of a German victory, he proceeded to rejoice in the shattering of the party system in this country, and also to denounce the neglect of science and scientific education by the governing bureaucracy. The voluntary basis of recruiting was another matter which came under his ban. He described it as being contrary to all the principles of eugenics, particularly in the absence of proper selection and classification, and the absence also of authority to decide that the energies of a man of certain scientific attainments would be better employed in the laboratory or classroom than in the trench. The present struggle had been compared in its social upheaval to the Civil War, but Professor Poulton thought that the Civil War, engaging as it did only thirty thousand or so combatants on each side, while the rest of a populous England looked on, had nothing like the impact which this war would have upon our generation. He conceived it the most pressing business of the Eugenics Education Society to unite with the scientists of every department in doing their utmost to see that, in the new form of government that was coming, science should have its proper recognition. Sir E. Ray Lankester, in moving a vote of thanks to the lecturer, agreed that the British Government was ignorant of, and therefore hostile to, science in all its branches. The ignorance extended from the highest Minister to the humblest official in the civil service. The real trouble, as he conceived it, was the servitude to snobbery. We were willing to see every post of importance go to no matter whom, provided he belonged to the right set, wore the right kind of collar, and had been to the right school. Professor E. W. Macbride, while almost equally severe in his criticism, thought that the lack was not so much the fault of the officials as of the way in which they had been brought up. Major Darwin, who presided, said that while it would be pleasant to believe that all suffering could be swept away by social reform, it was necessary to make the best of the world as it was. Just as brothers differed, so each generation might show an advance or a decline in comparison with that which preceded it, and social conditions would not prevent degradation if the inborn qualities of a nation were deteriorating. He quoted the saying of Lincoln: It is "for us to be here dedicated to the great task remaining before us"; that is, in the first place to winning the war, and then to seeing "that this nation, under God, shall have a new birth of freedom"; and added that Galton would have said that increasing freedom and racial degeneracy never marched hand in hand. If London was a little disappointed, the Liverpool branch of the society could not have felt that the address of its president last week in any way lacked in vigour. That stormy petrel, Sir James Barr, spared neither the working man nor the capitalist, but demanded that the Government should apply conscription all round in the interests of the nation. During the last eighteen months, he said, it had not merely been business as usual, but a large portion of the population, especially the middlemen and distributors, had striven to see how much they could make out of the war, a liberal donation to a charitable war object, and a good investment of profits in the war loan being sufficient to salve their consciences. The tax on war profits should not be confined to capitalists, but should extend to those unpatriotic wasters who had been on strike for an extra penny an hour, while the brave men in the trenches were not getting a penny an hour. Officers barely got a living wage, and yet a cool and calculating Government deducted

¹ See BRITISH MEDICAL JOURNAL, 1916, 1, 159.

a war income tax from their salaries. Could base ingratitude go much further? In conclusion, he said that the nation must prepare for the great trade war which was certain to follow as day followed night. All must be imbued with the spirit of work and the dignity of labour, for success would largely depend on the British working man.

WAR ORTHOPAEDICS.

THERE will be found at another page (318), in the course of a letter describing some of the medical work being done in Paris, an account of a demonstration given by Major Robert Jones of Liverpool at the Franco-American ambulance, Neuilly, which is still busily employed by the French military authorities. The staff of the ambulance got together a set of cases of gunshot wound of the upper arm, and Major Jones gave a sort of clinical lecture on the means which should be taken to place the limb in the position most favourable to its recovery with as large a degree of useful function as possible. After dealing with injuries of the shoulder-joint likely to end in a greater or less degree of ankylosis, and with fractures of the forearm, he went on to consider wounds involving the wrist. He advised that the joint should be kept in hyperextension (dorsal flexion), for should a stiff wrist result from the injury, the grasp of the fingers would be much stronger than if the hand were bent towards the flexor surface of the forearm. This position also affords a much better chance of securing a return of power in cases of wrist-drop. In them not merely the carpus and metacarpus but the whole palmar surfaces of the fingers should at first be supported; later on the length of the digital portion of the splint should be lessened as the patient regains power of extending the terminal phalanges by voluntary effort. The condition of wrist-drop, one of the causes of which is tight bandaging, is generally accompanied by malposition and excessive callus, it is amenable to the same line of treatment; the understanding of the condition has, perhaps, been confused by the term "ischaemic paralysis," which Volkmann applied to it, or to one form of it. When the condition is fully developed the fingers are contracted into the palm; the first thing to do, then, is to flex the wrist to the utmost and to straighten the fingers to the splint. When the fingers have been straightened to the palmar splint by degrees wrist and hand are extended and gradually hyperextended, a process which may take some months. In this way the contracted flexors are lengthened, and the stretched extensors relaxed. In the later stage massage and heat may be applied. Such cases are among those which go for treatment to the great hospital for men with crippled limbs which the French Government has established in the Grand Palais in Paris, described by Drs. Fortescue Fox and Campbell McClure at page 319. We have already on more than one occasion ventured to call attention to the extreme importance of orthopaedic treatment for men suffering from the crippling effects of wounds of bones and joints; especially is this the case when regarded from the economic point of view. A man, for instance, with a dropped wrist and stiff flexed fingers is quite incapable of following most trades, whereas if he retains control over the fingers he can, even though his wrist is stiff, execute many fine movements almost as well as a sound man, and can therefore become a useful member of the community. We believe that the army medical authorities are fully alive to the importance of early and efficient treatment of such cases, and we are quite certain that such treatment will not only render happier the lives of the men who undergo it, but will be an immense economic advantage to the country, to say nothing of the saving to the Exchequer in the matter of pensions.

BRONCHOSPIROCHAETOSIS.

A VALUABLE contribution to our knowledge of bronchospirochaetosis has been made by Dr. G. A. Lurie of Chicago, who gives a full account of the malady, illustrated by a report of a case he observed in Serbia.¹ The affection was first described by Castellani in 1905, who gave a description of its etiological agent, which he called *S. bronchialis*. Branch in 1907 confirmed Castellani's observations in the West Indies, and Jackson in 1908 in the Philippine Islands. In 1909 Waters recorded several cases in India, and Phalen and Kilborne a case in the Philippine Islands, where in 1911 Chamberlain described two cases. Recently numerous cases have been recorded in various parts of Africa by Chalmers, O'Farrel, Taylor, Harper, Macfie, and others; Fantham has made a very complete protozoological investigation of the spirochaete causing the disease, and has observed a coccoid stage. The spirochaete usually has tapering ends; it is very variable in length, thickness, and number of waves. Flagella are apparently absent. Dr. Lurie, following Castellani's classification, distinguishes three types of the disease—the acute, the chronic, the subacute. In the acute type the patient feels chilly and then develops fever, which lasts for a few days and is seldom very high. The expectoration is scanty and muco-purulent. Chronic bronchospirochaetosis may follow an acute attack, but more often the onset is slow and insidious. The expectoration is muco-purulent and may contain blood. Occasionally true haemoptysis is observed. The temperature may be normal, or there may be fever of hectic type. The physical examination is often negative, but, in certain cases, signs of slight consolidation may be detected. The general condition of the patient may remain fairly good for a long time, but occasionally wasting is rapid. The course is a long one, extending over several years, with periods of great improvement. The case observed in Serbia by Dr. Lurie belonged to the subacute type, the disease lasting for some months. The diagnosis of the malady is based on the microscopical examination of the sputum, which should be collected as free from saliva as possible and after the patient has gargled with sterile water. The spirochaete is generally present in very large numbers. The condition is distinguished from tuberculosis by the absence of Koch's bacillus; from bronchomycosis by the absence of hyphomycetes; and from endemic haemoptysis by the absence of ova of *Paragonimus westermanii*. Cases of mixed infection may occur. The prognosis is generally good, *quoad vitam*, but the disease may run an extremely long course. As regards treatment, Dr. Lurie emphasizes the great value of arsenic, as recommended by Castellani; Fowler's solution in his case gave very gratifying results.

ACETONURIA AND ACIDOSIS.

THE name "acidosis" was applied by Naunyn to the excretion of acetone, aceto-acetic acid, and beta-hydroxybutyric acid. Acidosis is of interest to the clinician because its occurrence, associated with diminished alkalinity of the blood, has been held to explain obscure occurrences such as diabetic coma and delayed chloroform poisoning. To the physiologist acidosis is of interest because the output of acetone and its congeners affords him the only clue he possesses to the faulty metabolism of fat. These substances are excreted mainly in the urine, and the influence of various diets and of periods of starvation on their excretion has recently been submitted once more to examination, by Dr. R. M. Lang,² with a view to casting fresh light upon the vexed question of their origin. In describing the experimental methods he employs the author notes that the solution of basic lead acetate habitually added to the urine in the course of such analyses

¹ Notes on Castellani's Bronchospirochaetosis, with report of a case, *Journal of Tropical Medicine*, December 1st, 1915.
² *Biochemical Journal*, Cambridge, 1915, ix, 455.

as these may of itself be a source of small amounts of acetone, when Shaffer's method of determining the acetone bodies is employed. Indeed, the error thus introduced may amount to over 100 per cent. in the case of normal urines; Dr. Lang has worked out figures showing the corrections that should be applied to eliminate this source of error in Shaffer's method. He finds that the quantity of acetone bodies excreted by the normal individual on a diet containing a sufficiency of carbohydrate is influenced chiefly by the protein in the food, and averages from 10 to 30 mg. a day. The output is much increased by starvation; the amount excreted during the first few days of starvation depends on the initial storage of carbohydrate and increases as soon as the ratio of the fat to the carbohydrate oxidized in the body becomes greater than about two to one. The administration of quite small amounts of carbohydrate to the starving organism brings about a great reduction in the acidosis, though relatively large amounts are required to stop it; protein acts less well and less rapidly than carbohydrate, as does glycerol, while alcohol is without effect here, and the exhibition of fat actually increases the acidosis. Dr. Lang concludes that when acetone bodies are excreted in excessive amounts they are for the most part derived from fat; he found that on the third day of a diet consisting of 320 grams of olive oil the urinary excretion of acetone and aceto-acetic acid reached over 0.8 gram, while the beta-oxybutyric acid was nearly 1.3 gram in the twenty-four hours. The diet, it may be remarked, proved both nauseating and depressing, and on the evening of the third day the breath was found to contain acetone in the proportion of something like 9 mg. an hour. The greater amount of the acetone, so called, in acetonuria is excreted in the form of aceto-acetic or diacetic acid; hence the term "acetonuria" might properly be replaced by the name "diaceturia," as Piper proposed in 1913. Dr. Lang also brings forward some evidence in favour of the possibility of the conversion of fat into carbohydrate in the human body, comparable to that which takes place in the hibernating mammal.

SIMPLES AND TISANES.

No English practitioner who has followed his profession on the Continent can fail to have been struck by the extensive use made of popular medicinal herbs as adjuvants to medical treatment properly so called. In England the preparation of infusions, decoctions, extracts, and liniments of herbs is now handed over to the manufacturing chemist, but there is a wide difference between the diuretic action of acetate or citrate of potash with infusion of buchu in the ordinary 6 oz. mixture and that of the same salt administered by the French method in a cupful of hot, freshly-prepared infusion, or the expectorant qualities of oxymel of squills and ipecacuanha given in a hot infusion of linseed and liquorice. From the time of Hippocrates the value of the ingestion of hot water in the treatment of febrile affections has been recognized and the prescription of herbal infusions and decoctions is, in the main, only a device for the purpose of inducing the patient to swallow the hot liquid, just as antisepsis is in great measure a device for securing cleanliness. Not one French patient in a dozen could be persuaded to drink a quart of hot water in the twenty-four hours, but if it be provided in the form of a herbal infusion, duly flavoured and sweetened, no difficulty is experienced. In the whole realm of medicinal nature there is no more active salutary diuretic and diaphoretic than hot water, and the physiological action of the latter is free from any drawback, whereas that of powerful drugs such as nitre, pilocarpine, sparteine, and the like, is often attended by injurious collateral effects. The absorption of the hot liquid and its free evacuation by the emunctories is a form of lavage of the tissues, stimulating metabolism,

and ridding the organism of microbial toxins and organic waste products. The French pharmacopoeia contains upwards of 200 *tisanes*, and no scheme of treatment is thought complete unless it provides for the ingestion of an adequate quantity of tisane. Instead of ordering "mist. alb.," the French doctor administers some Epsom salts or sodium sulphate in a hot infusion of senna, camomile, vervain, peppermint, or limeflower, with, on the whole, much more satisfactory results. In many parts of England a decoction of poppy heads and camomile is commonly employed as a fomentation for injured limbs, and its first aid use is cordially recommended by the doctors, since if it does nothing more it secures cleanliness of skin. Let us then, administer the bromides in a fresh infusion of valerian; nitre or ammonium acetate in a hot infusion of marsh mallow, couch grass, or pellitory; expectorants in a decoction of tussilage, pine buds, or serpentary; and a diuretic of potassium acetate in an infusion of elder flowers, saponaria, or borage. A cupful of hot vervain or camomile after dinner is an excellent carminative and facilitates digestion, and there are still people who like these draughts. Our professional forefathers were adepts in this matter, and in mediæval art the physician was usually represented scanning a sample of urine or culling herbs:

Excellent herbs had our fathers of old,
Excellent herbs to ease their pain—
Alexanders and marigold,
Eyebright, orris and elecampane,
Basil, rocket, valerian, rue
(Almost singing themselves they run),
Vervain, dittany, "call-me-to-you"
Cowslip, melilot, rose-of-the-sun;
Anything green that grew out of the mould
Was an excellent herb to our fathers of old.

COBRA VENOM.

THE action of cobra venom is generally supposed to be exerted in part on the central nervous system and in part on the terminations of the motor nerves. In a paper presented to the Royal Society on February 17th Professor A. R. Cushny, F.R.S., and S. Yagi stated that experiments they had made showed no symptoms of central nervous action in either cold or warm-blooded animals, but that death occurred from paralysis of the motor nerve terminations in striated muscle. In the frog this was accompanied by slowness and finally arrest of the circulation from a direct action on the heart. In mammals the failure of the respiration was due to the paralysis of the respiratory nerve terminations, but this was often accompanied by the inhalation of saliva, which accelerated asphyxia. The heart was also weakened by quantities of venom greater than the minimum lethal dose. A number of antidotes were examined without any great success, because no antidote appeared capable of ejecting the venom from its combinations in the tissues. The action on the peripheral organs was found to consist in a preliminary phase of stimulation followed by paralysis of muscle, whether striated or unstriated. This was common to all forms of muscle whatever the nature of the innervation, so that it could not be attributed to action on the nerve ends. The sympathetic ganglia and the secretory epithelium did not appear to be affected by the venom.

KEDANI FEVER IN SUMATRA.

A CURIOUS complaint, known as pseudo-typhoid fever, occurs in Deli, Sumatra. It is believed to be a variety of Japanese kedani fever, but Schüffner,¹ who has recently reported some cases, states that the transmitting agent of the disease in the two countries, Japan and Sumatra, is different. In Japan a small red mite, the larval form of an unknown *Trombidium*, is known to be the infecting agent; the true host of this mite is the field-mouse, which harbours the parasite often in large numbers, about the ears. Up to the present Schüffner has been unable to determine

¹ The Philippine Journal of Science, vol. x, Sec. B, No. 5.

the transmitting agent of the disease in Sumatra, but he thinks it must be a tick or mite. In 39 per cent. of the cases the original point of infection can be found. In the early stages a papule appears, which soon bursts, leaving a small dark area of blackish necrosed skin some 4 mm. in diameter; five to eight days later the slough is cast off, leaving a small round or oval ulcer with steep edges and the floor covered with muco-pus. Lymphangitis has not been observed, but the lymphatic glands in the neighbourhood of the ulcer are enlarged and tender, sometimes markedly so. The site of the initial lesion varies, but is commonest in the regions of the groins, the armpits, and the neck. The second characteristic symptom of the disease is an eruption which appears on the second or third day, and attains its full development between the sixth and eighth day; it then presents itself as a roseola, the raised spots varying in size from that of a hemp-seed to a threepenny-bit. This eruption closely resembles secondary syphilis; it covers most of the body, being thickly placed on the flanks and less marked on the face and extremities; it persists from eight to ten days longer, then becomes of a brownish colour, and slowly disappears. The temperature is raised, and the course of the fever can best be described by saying that it corresponds in all respects to that seen in enteric fever; it attains its maximum in four or five days, remains high for some time, and then gradually falls by lysis. Of other symptoms diarrhoea is uncommon; albuminuria may be present, and extensive bronchopneumonia has been seen in fatal cases; rheumatic pains are complained of in the smaller joints. The disease in Sumatra is considered to be much less fatal than the kedani fever of Japan. There are many points of resemblance between the two diseases, however; so much so, that the author believes the Sumatra disease to be only a variety of the Japanese.

Medical Notes in Parliament.

War.

Attested Men Found Physically Unfit.—At question time on February 21st the position of unmarried men who had attested and been rejected on medical grounds after August 14th, 1915, was raised, and Sir John Simon, not being satisfied with the answers, brought up the matter again in the debate on the vote of credit. Mr. Tennant, in his reply, said that it was quite clear that persons who had been rejected as medically unfit since August 14th, 1915, were outside the Military Service Act, but it did not follow that they were entitled to an armlet. When application for an armlet was made the War Office was entitled to ask why the man had been medically rejected. If rejected for some minor defect, he might still be of service to the country in other capacities. There was no desire on the part of the War Office to treat patriotic and innocent citizens unfairly. In reply to Mr. Thomas, Mr. Tennant had, on February 17th, stated as follows:

The conditions under which men can obtain armlets if they have been rejected at a recruiting office were published on December 27th, and are as follow: (a) Men who have been rejected on account of organic disease are given an armlet and their names are registered. (b) Men who have been rejected on account of eyesight or some slight physical defect are also given an armlet on condition that they will attest and be passed to the Army Reserve. In both cases, if the men can produce Army Form B 2505A and or Army Form B 2512A showing date and cause of rejection no further examination is necessary, but if the cause of rejection is not stated on the certificate it is necessary to re-examine the man to decide whether he belongs to category A or category B. There is no obligation on any man to submit to a second medical examination unless he is desirous of obtaining an armlet, but to obtain the armlet he must be medically examined unless his rejection certificate shows the cause of his rejection.

Enlistment of Consumptives.—In reply to Mr. Booth, Mr. Tennant said on February 21st that he feared that

there was some foundation for the statement that many consumptives had enlisted and thus for a period had relieved the approved insurance societies of sickness pay.

Medical Officers over 45.—On February 22nd Mr. Ellis Davies asked the Under Secretary of State for War whether it was the intention of the War Office that medical men now holding commissions in the Royal Army Medical Corps, being under 45 years of age and unfit for foreign service, should resign the same on the expiration of their present agreement. Mr. Tennant replied: Temporarily commissioned officers of the Royal Army Medical Corps under 45 years of age and unfit for foreign service are not permitted to retain their commissions after the period of service for which they engaged has expired. No further commissions are being given to men under 45 years of age unless they are physically fit for active service. It is hoped by these methods to set free men who are physically capable of undertaking general military duties and who have hitherto been employed in war hospitals in this country or have been engaged in private practice.

Fees for Medical Examination of Recruits.—Mr. Rendall asked whether the scales for payment to medical men for examining recruits (Southern Command Order 507, March 13th, 1915), set forth that for a whole day, defined as six working hours, and the examination of from thirty to forty recruits, the payment of £2 is ordered to be made; that in certain towns the doctors declined to examine more than thirty-one recruits a day, and for this work had been paid the full fee of £2; that in other places doctors worked from nine to twelve hours, and in one case (Dr. Weaver of Yeovil) 226 recruits were examined in fifteen consecutive hours, yet for these long hours and far greater number of examinations only the same fee of £2 was being paid as for the examination of thirty-one patients; whether there was dissatisfaction; and would he order the payment of £2 for each six hours' work and get his medical advisers to put these matters on a business-like footing. The Financial Secretary to the War Office (Mr. Forster) replied that if a few recruits were examined in a day, the fee was 2s. 6d. a recruit. £2 was the payment for a full day's work. In view of the evil results of hurried examination, it was not considered desirable to hold out to doctors pecuniary inducements to examine more than thirty to forty recruits in one day. He was not aware that the profession was dissatisfied with these arrangements. In reply to a written question by Mr. Rendall, having reference to an agreement to pay 2s. 6d. a head made by head quarters, No. 8 District, Exeter, with doctors undertaking to examine recruits in November and December last, Mr. Forster said that he was making inquiries.

3rd Western General Hospital.—In reply to Mr. Haydn Jones, on February 22nd, the Financial Secretary to the War Office said that the army accounts were not kept in such a form as to admit of arriving at the weekly cost of a hospital per bed. The 3rd Western General Hospital (Cardiff) was an administrative unit composed of many different buildings, and contained 2,000 beds. It had a staff of some 32 medical officers, who drew the army pay of their ranks, and of these 19 were local members of the profession, to whom it was open to pursue private practice.

PROFESSOR SYMINGTON, F.R.S., has published in the *Journal of Anatomy and Physiology* for January, 1916, a monograph on endocranial casts and brain-form. He throws much doubt on the conclusions drawn by eminent living anthropologists on "reconstructed" skulls of primitive men by inspecting the endocranial casts of the vault of ten skulls, each prepared with a cast of the related parts of the brain. He has come to the conclusion that the simplicity or complexity of the cerebral fissures and convolutions cannot be determined with any degree of accuracy from endocranial casts even on complete skulls. In no single instance did the fissures correspond to definite depressions indicating their position, and very frequently they were found to lie in various parts of their course over eminences on the cast. If, as these observations seem to show, reliance cannot be placed on endocranial casts from reconstructions of imperfect skulls, then it is not possible to estimate even approximately the relative degree of development of the various sensory and association centres in the cortex from the endocranial casts of the La Chapelle or Piltown skulls.

THE WAR.

MEDICAL WORK IN PARIS.

CRIPPLED SOLDIERS.

At the beginning of the war Paris was a great centre of activity for the British army, but after the Marne and the Yser it became of secondary importance in this respect, and not much has recently been published about the work being done there. The following extract from a private letter, dated February 17th, will therefore be read with interest:

... Such endless months seem to have passed since Paris first assumed its wartime garb that it is not easy to distinguish between its habits and appearance at the present time and those of the recent past. There are fluctuations, of course, but streets that empty early by night and are free from much bustle by day; the existence of numbers of hospitals in hotels and public buildings; the wearing of dark clothes by womenfolk; and the devotion of their spare time to unostentatious war work, have all grown to seem normal features of existence. Also normal, alas! seems the paucity of the calls made on our time by the wealthy floating population which formerly played so important a part in the professional and business life of permanent residents.

Still in this matter there is rather more variation; at times the larger and more fashionable hotels are quite busy. They were so recently, but were emptied again for the time being by the air raids.

As for the local branch of the British Red Cross Society, it still pursues the even tenor of its useful way. The greatly lessened use of Paris by the British has ended many of the calls previously made upon its energies, so it has reduced the number of its employees and the size of its controlling committee; but for the remainder it finds plenty of work. It has closed, it is true, all its extemporized hospitals, and the working arrangement between itself and the Hertford Hospital is at an end, but it maintains a dental clinic for the benefit of certain commissariat and like troops, as also a kind of an "infirmary first aid post" and buffet at the Gare du Nord. It also keeps going some working parties for the fabrication of garments for prisoners and for men still in the field, and does a good deal of agency and transport work in connexion with sick officers and nurses on their way to and from the convalescent homes on the Riviera, and with nurses, orderlies, and ambulance drivers who are passing through Paris on duty.

The Franco-American ambulance outside the Neuilly Gate continues to occupy a leading place among institutions of its kind. The French military authorities make ample use of its resources, and after some sixteen months of work there is no sign of slackening in the matter of energy and enterprise. The arrangements have been perfected in various ways, but the general system on which it is conducted remains much the same as it was before. It is under the general control of an American surgeon habitually resident in France, and is staffed by successive teams of surgeons supplied by different medical centres in the United States. There is thus never any lack of new ideas, but splints contrived out of plaster-of-Paris are not now in favour. Considering that the United States are almost the home of gypsum, and that men trained in American schools are particularly skilled in its use, its displacement at this hospital is rather striking testimony to the new ideas in the treatment of the wounds, usually septic, seen in this war.

Of the general keenness of the staff there was evidence last week. It was learnt that Mr. Robert Jones of Liverpool was in Paris for a few hours, so the staff promptly got together some 20 or 30 cases of gunshot wound of the upper limb, and induced him to use them as the basis of an impromptu clinical lecture or demonstration.

Among the points on which the visitor laid stress was the importance, in cases in which ankylosis of the shoulder-joint is to be anticipated, of keeping the upper arm during treatment in such a position that the face and top of the head can easily be reached by the hand. The advantage was that if ankylosis occurred with the humerus in this position, full utility of the upper limb was nevertheless

practically conserved, since tilting of the shoulder blade would enable the patient to effect most of the other movements of the hand required in daily life.

A second point was the desirability of treating all fractures of the forearm with the radius in a position of complete supination instead of halfway between that position and full pronation. Experience, he said, showed that adoption of the latter or classical position often resulted in serious loss of function, for though the hand could easily be pronated it could not be fully supinated. If, contrariwise, a case were treated with the radius completely supinated from the beginning, the worst that could happen was loss of natural pronation power, and this as compared with loss of supination power was a relatively small evil, since sufficient pronation could be secured by movement at the shoulder.

A third point on which Mr. Robert Jones dwelt related to gunshot wound involving the wrist. In these, he said, the joint should be kept not in a position midway between flexion and extension (that is, with the hand in the same line as the forearm), but in one of hyperextension, or, so to speak, dorsal flexion, for should a stiff wrist result from the injury, the grasp of the fingers would be much stronger if the carpus were pushed backwards than if the wrist were straight or the hand bent towards the flexor surface of the forearm. The same position, it was remarked, also afforded a much better chance of securing a return of power in cases of wrist-drop due to lesions of the musculo-spiral nerve. But in such cases not merely the carpus but the whole palmar surfaces of the fingers should be supported, the length of the digital portion of the splint being lessened as soon as the patient regained any power of extending his terminal phalanges by voluntary effort.

Additional interest was lent to this demonstration by the fact that it was delivered by Mr. Robert Jones on his way home from a prolonged expedition in the war zone. It appeared that he had received from the War Office an invitation to visit France for the purpose of examining for himself the difficulties encountered in dealing with the treatment and evacuation of cases of gunshot wound of the upper and lower limbs, and that he and his companion, Mr. Lynn Thomas of Cardiff, had been allowed to visit any hospital they wished not only at the bases but also in the fighting areas.

Incidentally, too, they had examined the working of a large number of medical annexes such as ambulance trains, hospital ships, convalescent camps, and bathing establishments. They seemed to have been very favourably impressed by the general character of the work done and the completeness of the arrangements made, and had discovered nothing to support a belief that there was lack of economy and judgement in respect of the number and distribution of medical men employed in the work.

Another institution rather in the foreground just now is a clinic whose work occupies a large number of rooms on the upper floor of the Grand Palais in the Champs Elysée. The patients are all soldiers suffering from loss or impairment of function in the upper or lower extremities resulting from wounds or other injuries received in the present war. The peculiarity of this institution is that all the means of treatment employed are of a mechanical and electro-therapeutic order. Probably none of them are unfamiliar to those cognisant with the more or less recent developments in these particular branches of medicine, but never before have their therapeutic powers, whatever these may be, been aggregated on quite the same lines.

There are some four or five different departments, each in charge of an expert, and all as a rule take part in the treatment of a given individual. Treatment, for instance, commonly commences by a patient having a stiffened joint exposed to blue light treatment till sufficient degree of analgesia is produced to allow of its being handled freely. He may be next sent to a room where an electrically-driven machine moves the joint in certain given directions, though more commonly the machine is one moved by the patient himself.

This part of the treatment finished for the day the patient is probably passed on to the officer in charge of one or other of three other departments, in all of which the aim is to improve the tone of the tissues around the affected joints and of the connected muscles. In one, treatment by radiant heat is employed, in another the stimulating effect of local baths of vibrating water and

faradic and other currents; in a third ordinary massage. There is also a department in which cases of particular interest are recorded by means of photographs, casts, and water-colour work; and yet another in which a very precise card index record is kept of the condition of each patient on coming under treatment, and on its completion. These records include an estimate of the functional inefficiency persisting, and will be used, it is understood, in determining the pension or allowance to be allotted to the individual.

There is a logical completeness about the arrangements of this institution which is certainly attractive, as well as characteristically French, but whether the results by the machinery mentioned could not be secured quite as well and more rapidly by simpler means is another question. The apparatus is for the most part of Swedish origin and remarkably ingenious in many cases. The movement to which the joints are submitted can be precisely regulated, and, as a rule, is partly active, partly passive. It is passive, inasmuch as the movement once voluntarily commenced by the patient, will be completed, if necessary, in the reverse direction by the action of an attached weight, which also regulates the force that the patient must exert.

Another institution well worth visiting at the present time is the new Hôpital Cochin, which for a long time has been growing up alongside Val de Grâce. Built for the most part in separate single-story pavilions, it represents to a large extent the latest French ideas of hospital construction, and, when all its special departments are complete, will be one of the most striking hospitals in Europe. Its annexes include a large theatre for teaching purposes, and a very notable x-ray and electro-therapeutic outfit. The latter is disposed in a series of rooms, each devoted to a different class of work, and colour photography, of which some very remarkable specimens are to be seen, is largely used for recording cases of exceptional interest.

PHYSICAL TREATMENT FOR DISABLED SOLDIERS.

ORGANIZATION IN PARIS.

We have received from Drs. R. Fortescue Fox and J. Campbell McClure, honorary secretaries of a committee of the Section of Balneology and Climatology of the Royal Society of Medicine, a report furnished to them by the courtesy of the French Government and of Dr. Jean Camus and his colleagues, on the work carried out in the Grand Palais and associated hospitals down to the end of 1915. The combined treatment, which has now been carried on some twelve months, includes:

1. Local applications of heat and moisture in strong currents of water ("The Whirlpool Bath") at temperatures rising to 120° and over.
2. Dry heat and local hot-air baths.
3. Light and other radiation baths.
4. Electrotherapeutics.
5. Manipulation and massage.
6. Mechanical treatment by a modified form of Zander apparatus.
7. "Re-education" of muscles and muscular groups by exercise and training.

Careful measurements are taken and graphic records preserved. The objects of the treatment are—

1. To hasten the return of wounded to their units at the front.
2. To reduce expense to the State by reducing disability entailed by wounds.
3. To reduce impairment of civil industry after the war occasioned by the numbers of seriously and permanently crippled men.

It is reported that half the patients treated return to their units and in a shorter time than is possible by other methods of treatment.

In addition to the large institution in the Grand Palais, there are in and near Paris seven other centres for combined physical treatment, and seven complete and four incomplete installations of the same kind in the French provinces.

Drs. Fox and McClure conclude their report as follows:

1. That it is by a novel association and combination of physical methods that our French colleagues have obtained

such good results, and that the hyperthermal "whirlpool bath," hitherto not used in England, forms an effective preparation for massage and mobilization, whether by hand or apparatus.

2. That such physical treatments are most successful when no time is lost in submitting the injured limb to them. Unfortunately that is not the case in England, nor yet in France. Regret is often expressed at the British health resorts that the wounded arrive so long after their injuries that the chance of cure or even amelioration is not infrequently lost.

3. That the number of disabled officers and men who would benefit by an approved physical treatment is now so very large—indeed that the need is so great and so pressing—that the facilities afforded by the health resorts cannot be regarded as sufficient to meet the emergency. In France, which is full of health resorts, it has been found necessary, as above mentioned, to set up eight centres for physical treatment in Paris, besides many in the provinces. We are aware that provision is being made for similar treatment at the British Command Dépôts, but the number of disabled men in the metropolitan area alone appears to us to warrant the establishment at the earliest possible moment of a central institute for physical treatment in London.

MODEL HYDROTHERAPEUTIC INSTALLATION.

Dr. Fortescue Fox has devised a model hydrotherapeutic installation for soldiers within the compass of a single hut (60 by 20 ft.), and the plans have been worked out by Mr. Harley M. Usill. The boiler which serves the baths and warms the building is in an annexe, and there is another annexe for linen and w.c.'s. The building is divided into two parts, the one for the baths and the other for the treatment of disabled limbs. The douche room is fitted with a series of shower baths, a nozzle douche to give varying pressure and temperatures, and a needle bath. In an adjoining room are three tubs for brine and effervescent baths. Beyond this, in the centre of the building, in a separate room, is a special feature of the installation—a pool bath, the temperature of which can be kept at about 60° F. day and night. It is designed for sedative treatments. The patient is seated in flowing water maintained at an even temperature by means of a calorifier fitted with a thermostatic valve. The sedative effect is proportional to the duration, which may extend to several hours. These prolonged "subthermal" baths are said to be specially indicated in cases of mental disturbance with depression and irritability, and are also used for insomnia and restlessness, and for shock, peripheral neuritis, and neuralgia. The pool is 8 ft. square, and ten men can be comfortably seated in it. The department for the treatment of disabled limb consists of two rooms, one with whirl baths and hot-air and radiation baths, and the other with tables for massage and manipulation, and with simple apparatus for mobilization of joints. Altogether sixteen cubicles are provided for rest and changing of clothes.

Shower baths, beginning at 95° to 100°, and finishing cold after two minutes, are used as tonic baths, as are also the nozzle douches, the stimulant effect of which can be heightened by increasing the pressure of the water. The douche should begin warm and finish after one, or at most two, minutes, as cold as can be comfortably borne. In atonic subjects two jets, one at 95° and the other cold, may be used simultaneously. The alternating douche is indicated for chronic neuralgias, for atonic and spinal neuroasthenia, for mental depression and malingering. Tub baths are commonly given at 98° F. for ten to fifteen minutes; brine and carbonated effervescent baths can also be given. Very brief hyperthermal baths, 105° to 115°, are useful in cases of sluggish circulation, fatigue fever, and muscular rheumatism. The first effect is to stimulate the heart and dilate the superficial arterioles; they must not be prolonged beyond two, or at most three, minutes, otherwise the first stimulant effect is followed by debility. Like other hot baths, they should be ended by a momentary affusion with cold water. In the local treatment for disabled limbs, heat, moisture, manipulation, and movement are all used as at the Grand Palais. The whirl baths for the arm and leg are given at 110° to 115° F., or 120° F., or even higher. Their duration is from fifteen to thirty minutes. They increase the arterial and lymph circulation in the injured part and promote the absorption of effusions; they also relieve pain and muscular spasm. They may be used in every case as a preparation for massage and movements, which are thereby rendered easier and less painful. Cases should be recorded on a card prepared by the Section of Balneology and Climatology

and approved by the Medical Research Committee, so that the results may be collected in a uniform way for the use of the Committee on the Medical History of the War. Copies of the cards can be obtained from Messrs. Adlard and Son, 76, Newgate Street, E.C.

JAUNDICE AT ALEXANDRIA.

At a meeting held at Alexandria on November 7th, 1915, a discussion was held on cases of jaundice in the military hospitals there.

Sir RONALD ROSS, who was in the chair, said that the main points at issue were, first, that a large number of the cases were probably only secondary or symptomatic, and occurred in the course of such diseases as dysentery and typhoid; and, secondly, that many cases appeared to be due to a specific disease. There were two types of specific jaundice known to occur in Egypt, one a mild type—*icterus levis*—with practically no mortality; the other, a very severe type—*icterus gravis*—with a mortality of 30 per cent. or more.

Professor KARTULIS divided the local varieties of jaundice into three principal groups: (1) Infectious jaundice due to direct infection by the mouth; (2) infectious jaundice with intermediate unknown causation; (3) infectious malignant jaundice of the Mediterranean with unknown causation. The two first groups were also described under the name of "Weil's disease." The first was caused by spoiled or foul food or by drinking stagnant water contaminated by sewage. It occurred among butchers, or among soldiers living under bad hygienic conditions or bathing in dirty water, and was not epidemic. The second group was sometimes epidemic among persons dwelling in unhealthy localities with defective drainage. The incubation period and duration were short in both groups, and a fatal issue seldom occurred even when the initial symptoms were alarming and intense. The onset was sudden, with rigors, fever, severe headache, and pain in the back and joints, followed by prostration, anorexia, thirst, and diarrhoea without colic. During the first three to five days the patient felt weak and could not sleep. On the fifth day, or later, the jaundice appeared. The urine contained albumin from the onset, was diminished in quantity, and of a dark greenish colour. The liver and spleen were enlarged and tender. From the fifth to the eighth day the symptoms improved and the jaundice faded. A febrile relapse with relatively slight symptoms frequently occurred during the fifth or sixth day. Convalescence, which began after ten to fourteen days, was protracted. During the first stage the tongue was coated and the pharynx congested. Vomiting was very common; labial herpes and persistent hiccough were seen in some cases, and epistaxis and petechiae were not uncommon. In addition to albumin, casts and sometimes blood appeared in the urine, and anuria with uraemic symptoms were present in many cases. Intense headache and severe pains in the muscles, especially in the calves, giddiness, stupor and delirium were common symptoms in nearly half of the cases. The pulse, at first 120 to 150, became normal with the appearance of jaundice. *Post mortem* the liver was seen to have undergone fatty degeneration, some lobules being destroyed, and this was the chief lesion in the kidneys also. The splenic follicles were enlarged and the leucocytes in the pulp augmented. In the third group were included yellow fever, bilious relapsing fever, the Smyrna typhus biliosus, the Nauplia typhus icterodes, and the Alexandria infectious jaundice or bilious typhoid. He dealt only with the infectious jaundice of Alexandria, Smyrna, and Nauplia. There was no doubt as to the identity of the disease in these three towns; in no other port of the Mediterranean did it occur in endemic or epidemic form. He sketched the distribution of the disease in the various outbreaks at Alexandria, which showed that its pathogenic agents must have some intimate relation to sewers and sea-water. It attacked persons of from 16 to 45 years old, but he had only seen 4 cases among women out of more than 300 cases. Most cases occurred during May and June or from September to November. During the last ten years, since the drainage had been conducted out to Chatby, the disease had become rare in Alexandria. Before 1898 probably 100 cases ended fatally each year. In 1898 there were 34 cases with 25 deaths, and in 1901 47 cases with 32

deaths. Afterwards the numbers gradually diminished to 1907, when there were 23 cases with 7 deaths. In 1908 there was a drop in the number of patients to 5, of whom 2 died. It had remained comparatively low since, only 3 cases occurring in 1915, of which 2 were fatal. In Nauplia and Smyrna the disease disappeared after the construction of a better drainage system. After an incubation period of one to three days, the disease commenced with rigor, severe headache, lumbar pain, prostration, increase of pulse-rate to 100 to 120, restlessness, and vomiting. During the next two or three days the conjunctivae became injected, and the patient looked as if drunk and was very restless. The tongue was foul, but red at the point and edges. The pharynx was much inflamed, and swallowing was difficult and painful. The epigastrium and hepatic region were tender. Epistaxis and herpes were common. Other early symptoms were constipation, diminution in the amount of urine, albuminuria, and intense thirst. These symptoms continued from three to six days, and on the fourth or fifth day the second stage set in with jaundice. If the disease took an unfavourable course, the myocardium became affected, the pulse becoming slow and perhaps intermittent. The liver was enlarged and very tender. The spleen enlarged only occasionally, and was rarely tender. Epistaxis, haematuria, and petechiae were often met with. Oliguria and anuria occurred, or the urine might contain, besides albumin and bile pigments, epithelial and blood casts. Hiccough was of bad omen. Parotitis was very common. At the end of this stage the fever lessened, but rose again after two or three days. If the fever became continuous and anuria persisted, the patient became apathetic and his respirations frequent and intermittent, the tongue dry and red, the pulse small and rapid or intermittent, and unconsciousness or delirium supervened. This was the third or typhoid stage. Sometimes anuria was replaced by polyuria. The stools became white and offensive, the jaundice remaining intense. Xanthopsia might be present. The weakness became extreme. Death occurred between the tenth and sixteenth day, and was due to uraemia, haemorrhage, pyaemia after suppurative parotitis, or general weakness. Convalescence was very protracted. The agent of the disease was probably ultramicroscopic, since repeated researches had failed to reveal it. The mortality was from 30 to 75 per cent. *Post mortem* jaundice and haemorrhages were found in an intense degree. There was no essential or constant lesion. The liver was nearly always large and congested. In the early stages its vessels were full of cherry-red coloured blood and its surface was marbled, but afterwards became yellow owing to fatty degeneration. The pancreas was usually large, hard, and yellow.

Captain N. BOULTON, R.A.M.C., said that among cases of jaundice recently under treatment a history of previous jaundice was obtainable in 10 per cent. He had been able in one case to determine the incubation period. A patient developed an attack within a week after exposure to infection. In nearly every case jaundice appeared in from three to five days from the onset. Nausea, anorexia, malaise, and mental depression were present in over 90 per cent. of the cases. Abdominal discomfort occurred after the slightest indiscretion in diet. Headache was present in 60 per cent. Vomiting and abdominal pain were noted in about 30 per cent. Diarrhoea occurred, but was not marked. Pruritus was rare. The temperature ranged from 99° to 103.5° F., and was usually between 99° and 100° F. The pulse was usually slow. The appearance of jaundice heralded a definite amelioration of the symptoms in over 90 per cent., but relapses were occasionally met with. The liver and gall bladder area were tender in nearly every case, but the liver was not definitely palpable. The gall bladder was felt in nearly 10 per cent. No death had occurred. The course varied from three to six weeks. Rest in the horizontal position was the most important factor in treatment. Urotropine and sodium phosphate were employed without definite results. The disease, except in its epidemic character and probable infectivity, differed clinically in no wise from ordinary so-called catarrhal jaundice.

Lieutenant GUNSON, R.A.M.C., had found that the tongue was moist and quite clean in all cases. The liver was invariably enlarged and tender, sometimes extending for 3½ in. below the costal margin. The spleen was also

greatly enlarged and tender. The heart was so definitely and persistently enlarged in many cases that it provided the leading feature of the clinical picture. The cardiac impulse was frequently palpable to the right of the sternum, and the cardiac enlargement was confined to its right side. The heart sounds remained clear, and there was no evidence of tricuspid regurgitation. The pulse was of good strength, but slow during the jaundice. Sinus arrhythmia was constant. General weakness persisted, and the patients, after having been out of bed for two or three weeks, could not perform gentle exercises without experiencing dyspnoea and giddiness, accompanied by increase of the pulse-rate. Usually some enlargement of the heart persisted, and was not reduced by rest. There were no fatal cases. All were treated by absolute rest in bed for several days. Drug treatment had no apparent influence.

Captain KERR, R.A.M.C.T., had come to the conclusion that it was not possible to dissociate the intestinal disorders, which had been prevalent, from the jaundice, and could not see in the latter a distinct disease. In the great majority of the cases under discussion there was a distinct history of diarrhoea or dysenteric symptoms, recent or remote. He did not think that the condition was that usually called epidemic jaundice.

Colonel TUBBY said that there appeared to be two prevailing types of jaundice: (1) Jaundice occurring in the course of some infection of the intestinal tract, as in dysentery and enteric fever. (2) Jaundice *per se* occurring in a definite epidemic form. In a large percentage of cases of the second class there was a history of a sore mouth and tender gums, followed by jaundice, feverishness, and heart weakness. He was inclined to think that the infection started in the mouth and gums, passing later to the intestine and bile ducts.

Captain ALLEN, R.A.M.C.(T.), said that of 30 cases of jaundice 22 had had either dysentery or diarrhoea previously. Eleven cases developed jaundice after admission and 6 of these were in beds near to patients suffering from that condition. In 2 cases only was the gall bladder felt, but its area was tender in the greater number. Dilatation of the heart and enlargement of the spleen were not detected. Four cases, admitted for purely surgical conditions, developed jaundice 8, 10, 14, and 19 days respectively after admission. They were all very ill, their temperatures varying from 100° to 103° F.

Major A. R. FERGUSON, R.A.M.C., regarded the jaundice met with as falling into two classes: (1) A mild form, (2) an extremely toxic form identical with that described by Professor Kartulis. Outbreaks of jaundice occurred among men camped on ground which had been occupied by horses in large numbers. He was of opinion that certain bacteria present in the faeces of such cases had a pathogenic significance. In two cases he had isolated *B. proteus fluorescens* in considerable numbers. Captain Mackie had recently isolated the same organism, as had also Jaeger and Banti some years ago. Like Colonel Tubby, he had observed herpetic or small septic lesions about the lips and gums and he thought that the initial congestion of the pharynx was also of special significance. In recent outbreaks in Egypt the severe toxic forms had not been met with. *Post mortem* both chambers of the right side of the heart were very dilated and flaccid. The liver suggested in some respects that of acute yellow atrophy.

From subsequent discussion, in which Sir RONALD ROSS, Lieutenant GUNSON, and Professor KARTULIS took part, it appeared that the cases from Chatby differed from those from Gallipoli; the former alone showed dilatation of the right side of the heart, were more protracted, and were accompanied by greater nervous depression and more enlargement of the spleen and liver.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

THE deaths noted below include those of two officers, Major W. B. Fry, who died nearly a year ago as a prisoner, and Lieutenant J. G. Bute, whose death is presumed.

Lieutenant John Gillis Bute, R.A.M.C., is believed to have been killed in France on October 29th, 1914. He was born in India, the son of Colonel Edward Bute, Army Medical Staff, and was educated at Trinity College,

Dublin, where he was a prominent member of the University Dramatic Society. After graduating M.B. and Ch.B., he entered the R.A.M.C. as lieutenant on July 31st, 1914. He was attached to the Grenadier Guards from September 7th, 1914, and was with them up to October 29th. On that date he was last seen alive attending Colonel Earle, of the Grenadiers, who had been wounded. As the enemy advanced, Colonel Earle was again wounded as he lay on the ground, and Bute is supposed to have been killed at the same time. Colonel Earle lost consciousness, and was unable to say with certainty that Bute was killed, but he appears never to have been heard of since that day. Had he been alive, and a prisoner of war, he would almost certainly have been able to communicate the fact to his relatives. His name, as far as we have noticed, has never appeared in the list of casualties, and for many months was retained in the *Army List*, being included in the list of lieutenants promoted to captains on March 1st, 1915.

Died on Service.

Major Walter Burgess Fry, R.A.M.C., is reported to have died of typhus fever as a prisoner of war at Wittenburg, in Saxony, on March 17th, 1915. He was educated at St. Thomas's Hospital and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1900. He entered the R.A.M.C. soon after and attained the rank of major on December 21st, 1911. He was taken prisoner in the retreat from Mons. Six months later an epidemic of typhus fever occurred among British soldiers who were prisoners of war at Wittenburg, and several officers of the R.A.M.C., who were also detained as prisoners, volunteered to attend the sufferers. Captains A. A. Sutcliffe and S. Field, R.A.M.C., also died there of typhus fever contracted from their patients, on March 12th and April 10th respectively, as stated in the *JOURNAL* at the time. Major Fry had given particular attention to the study of trypanosomes and tropical affections. In 1910 he contributed, with Mr. H. G. Plimmer, to the *Proceedings* of the Royal Society of London a paper on the experimental treatment of trypanosomiasis, and in 1911 a paper on the same subject to the *Journal of the R.A.M.C.* In that year he became protozoologist and assistant bacteriologist to the Wellcome Tropical Research Laboratories at Khartoum. His first contribution to the reports of those laboratories (1911) was on animal trypanosomiasis in the Anglo-Egyptian Sudan. In 1913 he published, with Captain H. S. Ranken, V.C., who died in France on September 25th, 1914, from wounds received a few days before, the result of further researches on the extrusion of granules by trypanosomes and their further development. It was published, with a note on methods by H. G. Plimmer, in the *Proceedings* of the Royal Society (June 12th, 1913). The last paper by Major Fry of which we find record is one on antimony in the treatment of syphilis, published in the *Journal of the R.A.M.C.* for 1914.

Died of Wounds.

Captain Alister Ralph Spiers-Alexander, I.M.S., died of wounds in Mesopotamia on February 9th. He was the son of Dr. Spiers-Alexander of Hampstead, and was educated at University College, London, taking the M.B. and B.S.Lond. in 1910. He entered the I.M.S. as lieutenant on January 28th, 1911, and became captain on January 28th, 1914. His name appeared among the wounded in the casualty list published on February 14th; he was then attached to the second battalion of the 7th Gurkhas.

Lieutenant-Colonel John Wilfred Stokes, R.A.M.C.(T.F.), died suddenly in a military hospital at Lachmere, Ham, on February 10th, aged 43. He was the eldest son of the late Rev. Arthur Stokes, of Mussoorie, India, was educated at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1895. After qualifying he filled the posts of house-surgeon to the children's hospital at Wicker, Sheffield, and house-physician to the Sheffield Royal Infirmary, subsequently becoming anaesthetist to that hospital, and demonstrator of anatomy in Sheffield University. When the war began he became Lieutenant-Colonel in command of the 3rd West Riding Field Ambulance from August 31st, 1914, and in that capacity went to France in April, 1915, but had twice been invalided home suffering from shell shock, and had been under treatment at Ham since December.

Wounded.

Major W. H. Odum, I.M.S., Mesopotamia.

Lieutenant (temporary) F. M. Vazifdar, I.M.S., Mesopotamia.

DEATHS AMONG SONS OF MEDICAL MEN.

Evans, David Owen, Lieutenant 17th Battalion Royal Welsh Fusiliers, son of Dr. D. D. Evans of Blaenau Ffestiniog, killed in France on February 14th. He was in a bank at Winnipeg when the war began, came over with the first Canadian contingent, and later got a commission in the R.W.F. Three of his brothers also came to England in the Canadian contingents and are in the Indian forces.

Freebairn, Buchanan William, Private 1st Newfoundland Regiment, C Company, eldest son of Dr. Robert Jardine Freebairn, stipendiary magistrate for the district of Ferryland, Newfoundland, died at Malta on October 23rd, 1915, of dysentery, contracted in the Dardanelles, aged 22.

Griffith, Richard Evelyn, eldest son of the late Dr. Herbert Tyrrell Griffith, M.D., of 5, Kensington Square, and formerly of the I.M.S., killed at Anzac, Gallipoli, on August 8th, 1915, aged 27.

Habershon, Kenneth Rees, Lieutenant 12th Battalion Rifle Brigade, second son of the late Dr. S. H. Habershon, killed in France on February 13th, aged 26. He got his first commission on September 19th, 1914.

Waite, J. Thorpe, Lieutenant 5th (Weald of Kent) Battalion the Buffs, or East Kent Regiment, eldest son of the late Dr. Waite, of Halifax, Yorkshire, killed in Mesopotamia on January 21st. His commission as lieutenant was dated August 22nd, 1914.

NOTES.

HONOURS.

CAPTAIN ERIC D. GAIRDNER, M.B., R.A.M.C.(T.F.), the son of the late Sir William Gairdner, has been awarded the French Military Cross for services in Gallipoli; he is attached to the Royal Scots Fusiliers, 5th Battalion (T.F.).

THE SWEDISH WAR HOSPITAL IN LONDON.

The proposal to establish a Swedish war hospital in London for wounded and disabled soldiers was only conceived two months ago. It received influential support not only from Swedes in London but also from Swedes at home, and lately also from many English friends of Sweden, and it has been found possible to establish a fully equipped hospital for thirty in-patients and a number of out-patients at 16-18, Paddington Street, London, W., where suitable premises have been acquired, reconstructed, and approved by the War Office. The hospital has been equipped with an operating theatre and an x-ray installation, and in adjoining premises, arranged to form part of the main building, accommodation for the staff has been found.

The General Committee, of which Count Herman Wrangel, the Swedish Minister, is Honorary Chairman, has obtained the services of a medical staff, including as honorary consulting surgeons Mr. F. Swinford Edwards and Mr. G. B. Mower White, and as honorary consulting physicians Dr. A. J. Jex-Blake and Dr. J. F. Jennings, in addition to Mr. H. B. Grimsdale (ophthalmologist), Mr. Harold S. Barwell (aurist), and Mr. Harry Forsyth (dental surgeon). Regular attendance will be given by Drs. Cyriax, Ryman, Swanberg, and Widegren, and Dr. K. Westman will be the resident medical officer.

The hospital is managed by a general committee, of which Messrs. H. Bendixson, C. Svedberg, and Axel Welin are the trustees, Mr. Allan Broman the honorary superintendent, and Major E. Mossberg and Mr. Louis Zettersten the honorary secretaries.

The hospital was formally handed over to the War Office on February 21st by Count Wrangel, who expressed the hope that it would be taken by English friends as a token of international solidarity. In receiving the gift on behalf of the War Office, Surgeon-General Russell pointed out how its work would tend to unite the two nations; and the Bishop of Willesden, who offered up dedicatory prayers, noted the fact that the day was the tenth anniversary of Count Wrangel's appointment as Swedish Minister at St. James's.

MEDICAL OFFICERS WANTED.

3rd Home Counties Field Ambulance.

Three medical officers are required in this unit. Applications to the Commanding Officer, Halton Camp West, Tring, Herts.

1st South Midland Mounted Brigade.

Three medical officers are wanted for imperial service to complete the 2nd line (T.). Applications to Major D. M. Spring, S.M.O., R.A.M.C.(T.), Head Quarters, Hempton, Fakenham, Norfolk.

England and Wales.

THE CARDIFF HOSPITAL AND WELSH MEDICAL SCHOOL.

LAST week the new wing of the King Edward VII Hospital, Cardiff, providing 150 beds, was formally declared open, and named the "Bruce Vaughan" wing. On the same occasion Colonel Bruce Vaughan, to whom the hospital and the Welsh medical school owe so great a debt, was presented with his bust in bronze, the work of Sir William Goscombe John, R.A. A portrait of King Edward VII was also unveiled in the entrance hall, and Lord Aberdare, who performed the ceremonies, observed that the new wing had been, in fact, in use for some time. General H. H. Lee, in opening the meeting, said that the hospital was greatly indebted to its treasurer, Lord Aberdare; the fact that he held that office had been a great assistance in obtaining the £46,000 which the erection of the wing had cost. The new wing contained pavilion wards for 110 beds, and, in addition, provided isolation beds. The Lady Aberdare operating theatre, which had cost £3,000, was one of the finest in the kingdom. Colonel Bruce Vaughan announced that Mrs. Nixon had doubled her contribution, raising it to £10,000. Of the additional £5,000, £3,000 was to be used to pay for the cost of the hospital chapel, and £2,000 to be placed in trust for a research scholarship in medical pathology. He then went on to speak of the delay which the action of the Board of Education and the Treasury had put in the way of the realization of the scheme for the completion of the Welsh national school of medicine. Sir Donald MacAlister in 1909, and Sir William Osler a little later, had said that Cardiff possessed all the material for a first-class full-time school, and by the munificence of Sir William James Thomas the money for the necessary buildings had been provided more than two years ago. Colonel Bruce Vaughan did not accept the contention that before the medical school was provided the proposed reconstruction of the University of Wales must be carried out. The hospital had been enlarged and equipped for teaching purposes, and apart from the need for the training of medical students there were four reasons why the school in the interests of Wales should be set up: (1) In the interests of the patients of the hospital, for wherever a complete school was established medical and surgical science stood higher than it did where there was no school, and the patients reaped the benefit, not only because there was extra attention, but also because it established discipline in the hospital, and therefore added considerably to its efficiency—no mean advantage in a hospital which would shortly have 480 beds. (2) It would promote research in pathology and therapeutics, for research in those subjects, if undertaken at all, must be undertaken jointly by a great hospital and a medical school. (3) It would form a centre for the diffusion of medical knowledge in the surrounding districts. (4) It would be an institution for consultative purposes to which practitioners seeking advice or knowledge might apply. The unwisdom of the delay enforced by the Government was heightened by the fact that Sir William James Thomas had promised to maintain the school buildings until such time as the Treasury saw its way to make the grant. The plea of "war economy" would not stand, for, as had recently been said, whatever else was economized in this war the grants to science and research should be increased. In an editorial comment on the meeting the *Western Mail* says that "the promoters of the Welsh School of Medicine are as determined as ever to proceed with their project. Their enthusiasm," it adds, "in fact seems to have been increased rather than diminished by the discouragements and delays with which they have had to contend."

FUNCTIONS OF THE PITUITARY BODY.

At the last meeting of the Liverpool Medical Institution Dr. Blair Bell gave an account, illustrated by lantern slides, of his researches on the function of the pituitary body. The experiments were made on dogs, under rigid aseptic conditions. Excess of pituitary secretion resulted in acromegaly, deficiency in dystrophia adipogenitalis. Complete ablation of the pars anterior caused death. Total removal of the pars posterior produced no symptoms. Separation or clamping of the stalk interfering

with the vascular supply of the pituitary body produced dystrophia adiposo-genitalis, carbohydrate tolerance, and genital atrophy, and he had been able to confirm his conclusions by control experiments and *post-mortem* observations. Infundibulin, the pressor agent, originated in the pars intermedia, and apparently passed into the pars nervosa. Dr. Blair Bell alluded not only to the pathological conditions due to lesions of the pituitary body, but touched on the therapeutic action of its extract.

LIVERPOOL HOSPITALS.

The report presented to the annual meeting of the Royal Southern Hospital, Liverpool, on February 15th, with the Lord Mayor in the chair, stated that during 1915 the in-patient department had 220 beds at its disposal; the average number of beds occupied was 180.85 and average number of days each patient was resident 26.57. The average cost per bed was £77 0s. 3½d. in 1915, as against £75 3s. 10d. in 1914. The average cost of each in-patient per week was £1 9s. 7½d. in 1915, as against £1 8s. 11d. in 1914. The total number of in-patients in 1915 was 2,688, a decrease of 178 as compared with 1914, entirely due to the longer stay of the patients under treatment. The military authorities had at their disposal 50 beds for sick and wounded soldiers; not all these beds had been so used, and the committee secured the consent of the military to make use temporarily of 20 beds for the civil patients. The out-patients in 1915 comprised 15,937 new cases, with 60,380 attendances. The average cost per attendance was 5.65d. The increased expenditure in this department, £1,421 5s. 3d., as compared with £1,323 7s. 8d. in 1914, was due to the larger number of patients treated and the additional cost of drugs, dressings, and instruments caused by the war. The Out-patient Maintenance Fund Committee reported that many members of approved societies under the Insurance Act were treated each year, and it expressed the hope that generous grants by these societies would be made towards the upkeep of the out-patient department. The special departments were those which are visited more frequently year by year by insured persons.

The annual meeting of the Royal Infirmary was held on February 17th, under the presidency of the Marquis of Salisbury. It was reported that the number of in-patients during 1915 was 4,328, against 4,898 in 1914. The out-patients numbered 26,078, against 25,316 in 1914. The cost of maintenance had increased from £21,136 in 1914 to £23,273 in the past year, and the debit balance was now £8,022. Dr. T. B. Grimsdale had tendered his resignation of the post of honorary gynaecological surgeon at the Royal Infirmary, which he had held for eighteen years, and the committee, in expressing high appreciation of his services and as a mark of esteem, recommended his election as honorary consulting gynaecological surgeon. Dr. Blair Bell, who was previously assistant gynaecological surgeon, was unanimously elected in his place.

In both these hospitals medical women have been appointed resident medical officers, and senior students have also acted. In neither hospital is there a medical man holding a post who is eligible to join the Army Medical Service.

Ireland.

DUBLIN CASTLE RED CROSS HOSPITAL.

A PUBLIC meeting, convened by the City of Dublin Branch of the British Red Cross Society, in support of the Dublin Castle Red Cross Hospital, was held last week at the Mansion House. The Lord Mayor presided over a large and representative gathering.

Mr. W. M. Murphy said the object of the meeting was to present to the members and supporters of the City of Dublin Branch of the British Red Cross Society a brief account of its inception, its aims, and a statement as to how those aims had so far been fulfilled. Shortly after the outbreak of war in August, 1914, a public meeting, convened by the Countess of Aberdeen, was held in the theatre of the Royal Dublin Society to consider what steps should be taken to promote Red Cross work in Ireland. A Red Cross bureau was established in Dublin

and classes in home nursing and first aid were formed, the programmes issued by the Department of Agriculture and Technical Instruction adopted, and speedily a large number of students qualified themselves to join Voluntary Aid Detachments, working from a Dublin centre. It was then decided that a City of Dublin branch of the British Red Cross Society should be officially organized and affiliated to head quarters, and recognition given to the newly-formed Voluntary Aid Detachments. One hundred and forty Voluntary Aid Detachments had been accepted for special service. Of these, 57 were at work in hospitals at home or abroad, and about 100 were working in dépôts for the making of war dressings. The total number who had attended the classes in first aid and home nursing was 1,726. A clothing and benefits department, as well as a fruit and vegetable dépôt, had been opened. At a meeting held on November 29th, 1914, in the Mansion House, the citizens of Dublin and the Irish public generally were invited to provide funds for the establishment of the Dublin Castle Red Cross Hospital, the King having graciously given his consent to the project. A generous response was made, the structural alterations and equipment of the hospital were carried out without delay, and in two months the hospital with full equipment of operating theatre, x-ray room, etc., was ready for use. On February 17th, 1915, it received its first patients, 100 in number. Since that date 1,206 patients had been received and 1,077 discharged; there had been only six deaths. The hospital had the advantage of having from each of the ten hospitals in the city a surgeon and a physician who gave their services freely; there were two x-ray specialists also on the staff. The resident medical staff consisted of a medical superintendent and an assistant house-surgeon, with three resident medical students as dressers. There was an efficient staff of trained nurses under a matron, and willing help was given in many ways by members of the Voluntary Aid Detachments.

A resolution, proposed by the Archbishop of Dublin, affirming that the Dublin Branch of the British Red Cross Society was worthy of the support of the Irish public, more especially of the citizens of Dublin, was carried, as was a vote of thanks, proposed by Mr. Justice Barton, to the physicians and surgeons of the clinical hospitals of Dublin, who had given, and continued to give, their valuable services freely to the Castle hospital. The President of the Royal College of Surgeons, in acknowledging the vote of thanks, said that the character of the men who had been admitted to the Castle hospital was splendid—a brighter, more cheerful, or more grateful lot of patients he had never seen. The indomitable gaiety and hopefulness of the men was something extraordinary, and it seemed to be a quality common to all—to Canadians, Australians, and New Zealanders, representatives of all the great Dominions. The Managing Committee, he said, deserved credit for the uncomplaining way they had complied with the demands of the medical staff.

BOARDS OF GUARDIANS AND THEIR MEDICAL OFFICERS WHO HAVE JOINED THE R.A.M.C.

It is to be regretted that two Irish boards of guardians—one in the co. Fermanagh and another in co. Westmeath—have cancelled the appointments, made by them at previous board meetings, of locumtenents nominated by their medical officers when joining the Royal Army Medical Corps. On the whole, Irish boards of guardians since the outbreak of war have facilitated recruiting for the naval and military medical services, but in this, as in all other matters dealing with their medical officers, there is no uniformity of action. Some boards, in addition to appointing the locumtenent nominated by their medical officer on joining the Royal Army Medical Corps, pay half, and in a few instances the whole, of his small official salary, while others refuse to appoint either the locumtenent nominated by their medical officer or to pay any portion of his salary while he is in the service of the Royal Army Medical Corps. Such treatment by boards of guardians of Poor Law medical officers who have joined the Royal Army Medical Corps is a formidable obstacle to medical recruiting from the ranks of this Irish medical service. In ordinary times there is an ethical rule, very generally observed amongst the Poor Law medical officers in Ireland, that no doctor should apply to act as locumtenent for another while on holiday or sick leave without

the consent of the doctor going on leave. The strict observance of this rule at the present time would be of the greatest help to medical recruiting in Ireland, and in those cases where a certain number of doctors ignore it, notwithstanding the representations of the Local Government Board and Insurance Commission, other steps should be taken to make such doctors subordinate their individual interests to the greater national interests.

MEDICAL DIALECT AND FOLKLORE OF THE NORTH OF IRELAND.

At a meeting of the Belfast Medical Students' Association held in the McMordie Hall, Students' Union of the university on February 18th, Sir John Byers gave an address on Medical Dialect and Folklore of the North of Ireland to a very large and appreciative audience. He dealt first with the practical importance to a medical man of knowing the strange words and phrases of the district in which he practised; he must know the language of his patients if he were to get a thorough insight into their troubles and woes. These words and phrases threw a light upon the history of a district, and it was a grave mistake to regard them as vulgar; they often represented archaic forms, and were survivals of words in the literature of centuries ago. Ulster possessed a dialect richer and more varied than any other area of the same size in the United Kingdom. This fact was due to the Celtic, Norman, Scottish, English, and French Huguenot immigration.

The lecturer then proceeded to give examples of dialect words and sayings descriptive of the various parts of the body and of the diseases which affect them, as well as of curious expressions employed by the sick; various charms and strange folk cures were touched upon; and, finally, the doctor himself, as described by the people in dialect terminology, was portrayed, and the foods used by the people, both in illness and in convalescence. An interesting discussion followed, and the meeting terminated by a hearty vote of thanks to the lecturer.

Scotland.

At the first meeting of the Central Midwives Board for Scotland, which took place on February 18th, Professor Sir Halliday Croom was elected chairman and Dr. Haig Ferguson deputy chairman. Matters concerning the arrangements for the future work of the Board were discussed, but no final decision was taken.

The Morison lectures before the Royal College of Physicians of Edinburgh will be delivered by Dr. Edwin Bramwell on Monday and Friday, March 6th and 10th, at 5 p.m. The subject is neurology of the war.

At the annual general meeting of the Glasgow Royal Asylum on February 17th Dr. L. R. Oswald, the physician-superintendent, reported that the number of admissions during the year was 93, as compared with 116 in the previous year. The decrease had occurred principally, if not entirely, among the men, and was to be explained by the number of men on service, by the financial prosperity enjoyed by those at home, and by a diminution of the causes producing mental disorder in the class from which the patients were drawn. The war coloured the symptoms produced in some cases, but was not the main causative factor in any. The absorbing interest of the national crisis, which had put self in the background, had thrown many who had previously no vocation in life into active social and philanthropic work, and had thus increased and not diminished the mental stability and general life. The saddest cases he had seen were those in which not the war itself, but the barbarous manner of its conduct by the enemy and the murder of innocent women and children had produced morbid depression closely allied to actual insanity. The directors reported that 534 patients had been treated in the institution during the year. The number of deaths was 37 and of discharges 65. Though the increased cost of maintenance amounted to at least 30 per cent., no change had as yet been made in the current rates of board.

DR. ALEXANDER MORLEY, of Craven Hill Gardens, Hyde Park, who recently died at the age of 79, left estate valued at £21,948.

Correspondence.

JEJUNAL FOR DUODENAL ULCERS.

SIR,—Sir John Bland-Sutton's explanation of the etiology of the so-called peptic jejunal ulcer (February 19th, p. 272) would not account for cases occurring within a short time of the performance of a gastro-enterostomy. A patient upon whom I did gastro-enterostomy had such an ulcer, which gave evidence of its presence six days after the operation, the diagnosis being verified both at the second operation undertaken for its relief, eight days after the operation, and at the subsequent *post-mortem* examination. It is inconceivable that structural alterations could take place in the jejunum in so short a time as six days, and some additional element must be at work in producing these ulcers.

The quotation from which the phrase a "vext duodenum and an agitated pylorus" is taken is to be found as a footnote to the chapter on dyspepsia in the second volume of Tanner's *Practice of Medicine*. The whole passage will appeal, I think, to Sir John Bland-Sutton's sense of humour.—I am, etc.,

Bettws-y-coed, Feb. 22nd.

NORMAN PORRITT.

THE PHYSICS OF A SURGICAL DRESSING.

SIR,—The vehement replies to Lieutenant-Colonel Primrose are sadly narrow in their vision.

Dr. Samways's last sentence is, however, a relief. "A" is not always good nor "B" always bad.

Surely the whole matter is one of osmosis. If you apply a dense fluid like glycerine to the surface of a wound there must be a flow of lymph from the tissues. If, on the other hand, you apply an easily evaporating fluid you tend to dry up the exuding lymph and to seal the wound. If you completely cover a pad of wool soaked in glycerine (with or without carbolic acid) placed upon an open wound it will on removal weigh much more than when applied. My contention is that this osmotic action has prevented the penetration of germs into the tissues, and that the carbolic acid kills those that are on the surface.

Another simple fact is that by no substance in the world can you reach and destroy germs which have penetrated beneath the surface, without also destroying the surface tissues. If, however, you apply a substance which will kill those on the surface, and if you apply it before many have penetrated beneath it, the tissues themselves will dispose of the remainder, provided you allow free exit for the corpses of defenders and invaders alike. A substance which encourages exosmosis and is at the same time germicidal and anodyne appears to me to meet most requirements. Such you have in carbolic glycerine.—I am, etc.,

London, E.C., Feb. 18th.

A. OGIER WARD.

THE INTRODUCTION OF CINCHONA TREES INTO INDIA.

SIR,—In Sir George Birdwood's letter on the introduction of cinchona trees into India Dr. T. Anderson's name is mentioned. Dr. Anderson introduced the cultivation of cinchona into the Bengal Presidency in 1861 from Java, taking also plants to the Nilghiris. He took charge of cinchona cultivation in Bengal at Darjeeling from the first steps, and his labours were completely successful. When he left India in 1869 he had overcome every difficulty in the cultivation of cinchona generally, and particularly as regards *C. Calisaya* and *C. succirubra*, the most valuable species. In a letter from the Acting Director of the Royal Botanic Gardens, Calcutta, dated February, 1871, to Sir William Grey, Lieutenant-Governor of Bengal, on the death of Dr. Anderson at the age of 38, it is stated, "No other person in India appears as yet to have succeeded in growing to economic advantage the invaluable species of *C. Calisaya*. Both *C. Calisaya* and *C. succirubra* now grow there better than in any other plantations in the world." I am informed on the best authority that *C. Calisaya* is not now and has never been a success in the Nilghiris; the climate does not seem to suit it. I am not aware that Sir Clements Markham took any part in the introduction or cultivation of cinchona in Bengal.—I am, etc.,

Horsmonden, Feb. 19th.

F. T. ANDERSON.

THE EDUCATION OF NURSES.

SIR,—Dr. Mildred M. Burgess calls attention in your issue of February 19th, p. 292, to the subject of the education of nurses and to the desirability of granting a diploma in nursing on the basis of an independent examination. I beg to state that, under the powers of a Royal Charter, the Royal British Nurses' Association has, since the year 1907, held independent examinations—written, oral, and practical—and granted diplomas to successful candidates.

The subject acquires additional importance from the fact that efforts are at the present time being made to place the training and certification of nurses on an organized basis. The powers for effecting that purpose have already been secured and are in operation.—I am, etc.,

London, W., Feb. 21st.

W. BEZLY THORNE, M.D.

THE ALLEGED WASTE OF ARMY MEDICAL OFFICERS.

THE following letter was published in the *Times* of Saturday, February 19th:

SIR,—I have recently had the opportunity of paying a prolonged visit to the British army in North France and Flanders in the company of a surgeon whose pioneer work in a particular department is as well known in the capital cities of our Central European foes as it is in the medical seats of learning of New York, Baltimore, Philadelphia, and Chicago. Before the outbreak of this Kultur-versus-democracy war I took an active part in the work of the St. John Ambulance Association and the British Red Cross Society, and had visited the head quarters of the Red Cross national organizations in Budapest, Vienna, and Berlin, whilst I enjoyed the great privilege of "doing my little bit" in the South African campaign; naturally, therefore, I was keenly interested to see how the Royal Army Medical Corps was performing its task of unforeseen and undreamt-of magnitude.

The primary object of the visit was to study a special point in the treatment of a particular class of injury in which one of us was interested, but fortunately we also had time and ample opportunity to investigate a question which is of quite a different character, which, from a national point of view, is more important and requires to be treated without bias, prejudice, or preconception. This matter was one which we had often heard discussed at home during the last few months, which appeared prominently in the press, and in regard to which we had heard and read statements of so definite a kind that we almost necessarily believed them to be true.

We shall be obliged, therefore, if you would afford us space to state that the statements as to the overstaffing of the medical units of the army in France seem to us to be quite unsupported by facts. We are of opinion that a perceptible reduction of the existing standard may in times of greater activity of "push" and counter-push lead to a condition which would lay the medical organization open to legitimate adverse criticism.

This opinion is founded on facts we had ample opportunity of glean for ourselves, since the primary object of our visit brought us into immediate contact not only with the regular officers of the Royal Army Medical Corps, but also with the numerous medical men until recently in civilian practice who hold temporary commissions in that corps, and now form the large bulk of the whole medical service in France. We thus not only saw things for ourselves, but heard the opinion of men who, despite the temptation to return home to look after their own practices, affairs, and personal comforts, continue to perform the duties which they have taken up.

We were thrilled with admiration at the existing perfection of the hospitals, both at the base and the front, and at the marvellous organization which exists throughout the vast medical service. Every detail is considered and seen to, and indeed any suggestions made were everywhere welcomed in the same spirit as one of us indicated in the *BRITISH MEDICAL JOURNAL* not long after the outbreak of this war. It would be impossible in a letter of this kind to enumerate the thousand and one items which struck us as evidence of the businesslike capacity, spelling efficiency and economy, everywhere apparent.

Wherever we went we found under the varying conditions always the same admirable organization and the same high administrative standard for the prevention of disease, and for the treatment of our sick and wounded soldiers. The special departments which have been created for dealing with ophthalmic, dental, skin, and foot troubles complete an organization which is worthy of the highest and best traditions of the British race. It was a source of

pride and confidence to us, who have our only sons serving in the British army, to have at the end of our visit an opportunity to see at the General Head Quarters tables and graphic charts showing us at a glance how every detail is considered and controlled by the Director-General, Sir Arthur Sloggett.

As a member of the War Executive Committee of the British Red Cross Society, which is working in the closest association with the Order of St. John, it is not for me to praise the work which is being done by these two national organizations, but it is known that the aid they give in respect of hospitals and transport is a most valuable auxiliary.

I have the honour to remain yours faithfully,

J. LYNN THOMAS, C.B., F.R.C.S.

P.S.—I have submitted this letter, with the exception of paragraph 1, to my friend in khaki, and he endorses every statement without reservation.

*** In a letter published in the *Medical Journal of Australia* for January 8th, 1916, and therefore written a good deal earlier, Lieutenant-Colonel Gordon Craig, A.M.C., deals with various causes which had prevented the members of the medical profession in Australia from enlisting even more freely than they have.

One of these, he said, was the statement that many medical men are idle at the hospitals in the war area. He called it a half truth, and therefore worse than a lie. "I have realized," he wrote, "that a military organization must be worked out on a maximum, and not a minimum basis, so that when the extraordinary call comes, it may not collapse. The whole history of the war shows big actions, alternating with periods of comparative inaction. During the latter, it is obvious that some men must be idle; but it is in their presence, in their readiness for emergency, that their military strength lies." Another lesson which, he said, must be learnt, was that every man must be ready to do any duty of a medical nature that the requirements of the service demanded. "If an opportunity arises for him to use his special gifts of training, such as that of surgeon or physician, so much the better; let him seize it. But if there is not that work, he must do uncomplainingly the ordinary work of military routine." Another cause of dissatisfaction mentioned was the fear that professional inferiors might occupy a higher position. "This," he wrote, "is bound to happen in a few isolated cases." Medical men are naturally independent, and their training develops that independence, but "as soon as it is realized that the authority is exercised in military matters only, the irksome feeling disappears. Sufficient freedom of thought and action is left to give scope to individuality. If the position is untenable it is always possible to transfer to another unit. In any case matters soon right themselves; the incompetent man is removed to a position more suited to him; and in a game of this sort, what matters it whether a man is captain or a colonel, so long as he serves his country? the rank does not make the man." As to another difficulty—the want of previous military training—he admits that it is real, and adds: "One month's training in the evening by a military instructor would give every medical man enough knowledge to 'carry on' his duties as a military officer. Schools for this purpose could be formed and organized by the local Branches of the British Medical Association."

The Services.

EXCHANGE DESIRED.

CAPTAIN, R.A.M.C.T.F. (civil hospital surgeon), at present in England serving as Medical Officer to Divisional Train, A.S.C., wishes to exchange with an officer in base hospital, or other appointment where surgical work is available, at home or abroad.—Address No. 850, *BRITISH MEDICAL JOURNAL* Office, 429, Strand, W.C.

PROFESSORS MARAGLIANO of Genoa and RUMMO of Naples, vice-presidents of the Italian Society of Internal Medicine, have issued an appeal for funds for the erection of a statue of the late Professor Baccelli to be placed in the Policlinico at Rome, in the foundation of which Baccelli took a leading part.

THE Cambridge University Press announces that it has become the agent in Great Britain for the *Journal of Cancer Research* (quarterly), the organ of the American Association for Cancer Research, and of the *Journal of Immunology* (bi-monthly), the organ of the American Association of Immunologists and the New York Society of Serology and Haematology. The subscription price for each journal is 25s.

Obituary.

SIR WILLIAM TURNER, K.C.B., F.R.S.,

PRINCIPAL AND VICE-CHANCELLOR OF THE UNIVERSITY OF EDINBURGH.

(With Portrait on Special Plate)

THE late Sir William Turner's long life was so rich in opportunities and so fertile in fruitful fulfilment that any attempt to enumerate, much more to describe, his activities and their realizations is at once embarrassed by the number of the competing themes and the variety of their interest. For forty years at least there has been little if anything of lasting value achieved in the various departments of scientific medicine and of medical politics with which Sir William has been associated that was not in some measure at least the work of his hands and brain. So complex an achievement cannot adequately be treated in an obituary notice; it demands a biography.

More than eighty-four years ago the future Principal of the University of Edinburgh was born in Lancaster. He received his medical education at St. Bartholomew's Hospital, and it is no less than sixty-two years since Professor John Goodsir chose the young M.R.C.S. Eng. as his senior demonstrator of anatomy in the University of Edinburgh, and so determined once and for all the direction of the activities which were to be so closely bound up with medical progress in the Scottish capital. Turner graduated M.B.Lond. in 1857, and from that year right up to the past week he marched ever onward in the path into which his feet had been led by Goodsir's choice, a more momentous one than the maker of it ever knew. Men who were undergraduates at Edinburgh in the later Fifties of the last century speak of another demonstrator whom some of them think was more brilliant if less gifted than Turner, but he fell out of the running, and the way was open for the Lancastrian to succeed to the chair of anatomy on Goodsir's death in 1867. Having been thirteen years demonstrator, Turner was for thirty-six years professor of anatomy, and then (in 1903) only resigned the professor's chair in order to occupy the seat of Principal of the University, a high place which he filled and adorned to the end. For part of the time he was also Dean of the Medical Faculty. During these sixty years there were many notable occasions in the history of the University of Edinburgh, and in nearly all of them Sir William Turner played an important and often a leading part; mention need only be made of three of the most outstanding—the raising of the funds necessary for the building and opening of the new university buildings and McEwan Hall, the tercentenary celebrations (in 1883), and the establishment and guiding of the Carnegie Trust (from which the University of Edinburgh, in common with the three other Scottish universities, has benefited so conspicuously).

Whilst the appointments which have been named mark what may be called the main current of Sir William Turner's professional life, there were several side streams, some of which became almost as great. There was, for instance, his work on the General Medical Council. To this body he was elected in 1873 as representative of the University of Edinburgh, and he remained a member of it, with the exception of three years (1883–86), till he was made its President (in succession to Sir Richard Quain) in 1898. He occupied the chair till 1904, and remained a year longer on the Council. Then, again, there was the part he played in connexion with scientific societies and medical institutions; he was a member of the Medical Acts Royal Commission in 1881; he was a Fellow of both the Royal Societies (of London and Edinburgh) and President of the latter; he was President of the Anthropological Section of the British Association, and later (in 1900) of the British Association itself; and he was F.R.C.S. of England (1893) and President and Fellow of the Royal College of Surgeons of Edinburgh. Yet again there was the literary current in his life's activities, with its numerous articles embodying the most minutely detailed and scrupulously accurate of researches on human and comparative anatomy, from his work on placentation (an epoch-making classic) through a long series of contributions on craniology to his masterly exposition of *Pithecanthropus*; with the article on "Anatomy" for the

Encyclopaedia Britannica, which appeared afterwards as a separate volume; and with the conduct and editorship of the *Journal of Anatomy and Physiology*, always a labour of love to Sir William. There was also his connexion with the Volunteer movement from the days when, as Captain Turner, of the Q.E.R.V.B. (IV or University Company), he drilled his men (not a few were also his students) in the quadrangle of the old university, to the more recent days when he was made honorary lieutenant-colonel (V.D.) of the brigade. Only a fortnight before his death he took part in the Officers' Training Corps' service in St. Giles's Cathedral. There were other directions, too, in which his wonderful personality made itself felt, and of some of these, as well as the ones which have been named above, a few of his many friends will record their memories.

So many were the ways in which he influenced others that it is difficult to pick out any one as the most important, yet perhaps first place should be given to his work as a teacher of anatomy. For he not only taught students, he instructed future professors of the subject, and so strong was his personality and so unique was his method that the senior who had reached his third year had not lost the impression he received as a junior attending his first lecture, that ever-memorable one in which Sir William, dealing with the vertebral column, announced that "man was an erect animal," and literally put some backbone into the youngsters listening to him. His lectures were impressive, in fact everything that he did could be so characterized, and one felt instinctively that the information behind them was massive and absolutely exact; his utterance was clear, each word falling with a distinctness which, to quote one of his own favourite expressions, left "no dubiety" in the mind of the hearer; and his habit of looking closely at the object he was describing and only glancing now and again at his listeners had a fascination which kept their gaze fixed on him all the time. No one could doubt that there were immense stores of knowledge behind the facts which he stated with such security, and no one as a rule dreamed of asking a question after lecture in the hope of altering by an iota any pronouncement which had been made. One day, however, a venturesome student drew the professor's attention to a rare anomaly in the insertion of some muscle or in the ramifications of a nerve, and, exhilarated with the thought that perhaps he had discovered a hitherto unrecorded variety, asked his teacher if he had ever seen such a thing before; the reply, given kindly but quite firmly, was that whilst Sir William could not at the moment recall any such occurrence his pupil must not on that account consider that no such occurrence had taken place, for he (his teacher) had seen a great many things and had not tried to retain them all in his mind.

That the expression "he instructed future professors" is no mere figure of speech is shown by the following list (perhaps incomplete) of his pupils who became professors in anatomy: The late Professor Morrison Watson, Owens College, Manchester (who married a sister of Lady Turner); the late Professor D. J. Cunningham, who succeeded him in the Edinburgh chair; Professor Arthur Robinson, late of King's College, London, and Birmingham University, the successor of Cunningham; Professor Arthur Thomson, Oxford; Professor Johnson Symington, Belfast; Professor Robert Howden, Durham University; Professor J. T. Wilson, Sydney University; Professor A. M. Paterson, Liverpool University; Professor P. H. Bryce, Glasgow University; Professor David Hepburn, Cardiff; Professor Richard Berry, Melbourne; Professor James Musgrove, St. Andrews, now succeeded by Professor Waterston, St. Andrews; Professor Primrose, for a time Professor of Anatomy, Toronto University, now Professor of Surgery; Professor Lamont, University College, Dundee.

No life so full and so strenuous as Sir William Turner's could evade honours, and indeed they poured in upon him from all sides. He received his knighthood in 1886, and the K.C.B. in 1901; he was Knight of the Royal Prussian *Ordre pour le Mérite*; Glasgow, St. Andrews, Aberdeen, Montreal, and the Western University, Pennsylvania, gave him their honorary Doctorate of Laws; from Oxford, Durham, and Toronto came the Hon. D.C.L.; he was an Hon. D.Sc. of Dublin and Cambridge; and he was an honorary member of the Royal Irish Academy, as well

as of learned societies in Paris, Berlin, Rome, Petrograd, Brussels, New South Wales, and other places.

Sir William Turner's chief, if not his only, recreation was foreign travel, and his knowledge of places and things was really extraordinary. He had travelled with enthusiasm all over Italy, France, and Belgium, and he also visited Canada and the United States. His appreciation of ecclesiastical architecture was a part of his great mental equipment, and there were few cathedrals in the European countries above named as well as in England with whose structural features he was not well acquainted. He was undoubtedly a great conversationalist, and his wonderful memory, drawing as it could upon immense stores of facts, made him most reliable when dealing with past events.

An Englishman by birth and ancestry, he had an abounding love for Scotland and things Scottish, and perhaps his friends in the North paid him the highest compliment they knew when they expressed their surprise that he had come from the other side of the Cheviots. In 1863 he married the eldest daughter of Mr. Abraham Logan of Burnhouses, Berwickshire. Lady Turner predeceased her husband in 1908. Sir William Turner is survived by three sons and two daughters. One of his sons is Dr. William Aldren Turner, physician and lecturer in neurology to King's College Hospital, London; another is Dr. A. Logan Turner, lecturer on diseases of the ear and throat in the University of Edinburgh; and the third, Mr. Francis R. Turner, is a farmer in Roxburghshire.

As was announced in the JOURNAL last week (p. 287), Sir William Turner was in the enjoyment of his usual good health until ten days before his death. Then gastric symptoms manifested themselves, and he passed away early on the morning of Tuesday, February 15th.

The funeral service took place in St. John's Episcopal Church, Edinburgh, where for sixty years he had always worshipped, and was attended by so large a gathering of the representatives of public bodies as has been rarely seen.

Sir William Turner as Anatomist and Anthropologist.

Professor ARTHUR KEITH, M.D., F.R.S., Conservator of the Museum of the Royal College of Surgeons of England, writes:

When the medical history of our time comes to be written Sir William Turner's name will find a place in the very first rank. To those who love the spectacular his work will not appeal; like another man, with whom he had much in common—John Hunter—he never startled his contemporaries with any single outstanding unforgettable discovery, yet his life—from the publication of his student effort (under the aegis of Sir James Paget in the summer of 1854) until the publication of his great monograph on the Scottish people at the close of last year—was a continuous succession of discoveries. As they were made he fitted them deftly into the mosaic work of acquired and growing knowledge. To appraise Sir William Turner's life-work at its proper value it has to be viewed, not as a series of isolated, often splendid, fragments or pieces, but in its proper setting—as an intrinsic part of the general progress in medicine which has been made in our time. Like Hunter, he was a builder, not restricted to one single line of endeavour, but covering many fields—physiological chemistry, pathology, human anatomy, physiological anatomy, comparative anatomy, zoology, anthropology, and medical history. Like Hunter he built a great museum; he realized that specimens could still live and speak when the printed word was dead. Unlike Hunter he was a statesman; the progress of the community was as much to him or more than the success of his own affairs. On the thread of his life is strung all the beads of British anatomy for half a century and more.

Sir William Turner's career appeals to me more than any other medical man's of our time. It is so continuous, consecutive, logical, fruitful, and full of the right kind of romance. He was, as he often said himself, a "Lancaster lad"; his father, as I learnt from my friend Professor William Stirling, was an upholsterer; he died at the age of 40, leaving his son William a boy of 5. I have notes of him attending "Teddy" Howard's school some seventy odd years ago and catching "bits of coloured wool with a crooked pin, thrown on the floor by a little girl sitting on

a form across the room." In due time he was apprenticed to Christopher Johnston, surgeon, and with him a double influence was brought to bear on the young Lancastrian. When his apprenticeship draws to a close there is no doubt about the hospital he is to proceed to. Richard Owen, a Lancaster lad, was at the height of his fame in 1852 when Turner had to choose his hospital, and, like Owen, he selected St. Bartholomew's. Owen in 1852 was 48 years of age, and was then making up his mind to leave the College of Surgeons for the British Museum. Turner was a lad of 20 in 1852. Paget had just finished the catalogue of the Pathological Collection at the Royal College of Surgeons.

When Turner arrived as a student Sir James Paget was 38 years of age, had given up the resident wardenship of the school, and borrowed money to become the tenant of 24, Henrietta Street. Turner's old master, Christopher Johnston, had engrafted a love and knowledge of chemistry in his pupil; in 1854 Turner is awarded honours in chemistry by the University of London; his personality and his knowledge won him a high place in Paget's esteem. In the same year (1854) Paget communicated Turner's paper to the Royal Society—the one in which he shows that the reducing substance in cerebro-spinal fluid is not a sugar. The fluid had been drawn from a case of spina bifida under Paget's care.

I have said Turner's life is full of romance. When he left Lancaster he followed in Owen's track; the next turn of the wheel of fortune sent him off to Scotland—right into the heart of the most jealous and keen of all medical corporations—the heart of medical and particularly anatomical Scotland. It was Paget who turned the wheel. That grim Calvinist, John Goodsir, the best student of the human body Scotland ever produced, was ill with overwork and with the disease which was ultimately to wreck his health, when he came to see Paget at St. Bartholomew's in 1854. He looked then old and worn, but he was exactly the same age as his friend Paget—42. The result of Goodsir's visit was that Turner was installed as senior demonstrator of anatomy in the University of Edinburgh. But there were three connexions formed at St. Bartholomew's Hospital which were to exercise a permanent influence on Turner's career. There was, in the first place, the close tie he had formed with his teacher, Sir James Paget. In 1863, when a second edition of *Lectures on Surgical Pathology* was called for, the task of preparation fell on the senior demonstrator of anatomy in Edinburgh. There was the intimate friendship which he had formed with his fellow-student at St. Bartholomew's, George Rolleston. What the one did at Oxford the other did in Edinburgh, and vice versa. When Rolleston's premature loss to science occurred in 1881, it was his friend Turner who collected his papers into two volumes, and edited them in company with Professor E. B. Tylor of Oxford. Rolleston's marked bent towards anthropological investigation had an undoubted influence on Turner. There is still another St. Bartholomew's connexion of his which has had an important bearing on the development of anatomical literature in this country. It was through his hospital and through Paget that Turner's friendship with George Murray Humphry of Cambridge was formed. Humphry was Turner's senior by twelve years; Humphry had left St. Bartholomew's ten years before Turner entered it. When Turner set out for Edinburgh in 1854, Humphry was a deputy teacher of anatomy and surgeon in Cambridge. When in 1867 a proposal was broached for a journal to serve the needs of British anatomists and physiologists, it was the two "Bart's" men who conceived and carried the scheme through. By their means they gave an enormous impetus to the progress of anatomy amongst English-speaking peoples. There is another St. Bartholomew's student whose name richly deserves to be recalled because of its connexion with anatomy and with Turner—the late Mr. C. B. Lockwood. Turner and Humphry founded the *Journal of Anatomy* in 1867; twenty years later Mr. Lockwood, with the help of Humphry and of Turner, founded the Anatomical Society. St. Bartholomew's School had no professed anatomist in those days, yet it formed the cradle of the three leading British anatomists of the Victorian period.

I do not suppose that William Turner, when he went to Edinburgh in 1854, had the least intention of making a

home there, any more than Lister had when he went to see Syme at a rather earlier date—1852. Lister was getting married when Turner joined Goodsir in Edinburgh in 1854. We soon find those two young men making a combined research—using carmine as a differential stain for the axis cylinder of nerve fibres. In those days Lister was really an anatomical physiologist—perhaps “biologist” is the better term for him—and Turner was a physiological anatomist. In the dissecting-room at Edinburgh Turner came under the spell of Goodsir—no man of parts could resist that spell. Goodsir proved to be Turner's real master—not Paget. Through Goodsir he absorbed the spirit and the traditions of the Edinburgh school—the standard set by the Monroes, by Barclay, by Knox, and, above all, by Goodsir himself. The Edinburgh anatomists took a wide view of their subject; mere applied or surgical anatomy was held at a discount; they desired their subject to be regarded as a science, resting on a basis of comparative anatomy. Hence the catholicity of their pursuits; one day they are dissecting some fish or whale; on the next they are recording the anomalies of the human body or seeking to apply morphological laws to its structure. For eleven years Turner served under Goodsir; he had Professor Clelland and Professor John Chiene as junior colleagues in the dissecting-room. In 1867, at the age of 35, he succeeded to the chair of anatomy when Goodsir's tragic end came at the age of 53.

Before he succeeded to the chair certain events occurred which give us a key to his strong, firm, honest nature. In 1863 Huxley came down to Edinburgh and gave the substance of “Man's Place in Nature” in the form of public lectures. His teaching and deductions were thoroughly distasteful to the orthodox public; Owen and Goodsir were in sympathy with the public point of view, and made no secret of their opposition to Huxley and to Darwin. It is quite clear from papers published by Turner during the period of the Owen-Huxley controversy—“Anatomical characters of a human cranium found at Amiens” (1863), and “On human crania, allied in anatomical characters to the Engis and Neanderthal skulls” (1864)—that he makes his position quite clear; Goodsir's opposition did not prevent his becoming a follower of Darwin and a believer in evolution, but his statements are temperate and judicious and destitute of that sting which rouses unscientific controversy. He was a statesman even when he was arguing a scientific truth.

It is of importance to note the “Owen-Huxley” controversy, for that and the discovery of the remains of prehistoric men about the same period induced many anatomists to apply themselves to that ill-defined branch of knowledge now known as “anthropology.” Turner's enthusiasm for the subject dates from the Owen-Huxley controversial period. When his students went to their homes at the end of a session they were duly impressed with the documentary value of human skulls—ancient and modern—and the need of gathering and saving such things. When these same students became graduates of the university, and came to hold medical posts abroad, they never forgot the teaching and craniological needs of their old professor. By such means Sir William Turner collected in his museum representations of all the races of the world. His classical monographs on the craniological features of the Scottish people, both ancient and modern, on the peoples of the empire of India, on the extinct natives of Tasmania, on the natives of New Guinea and of Borneo, were based on material which he gradually accumulated—chiefly through the help of his devoted pupils. He was the first to make an accurate study of the development of the lumbar curvature. In anthropology and in anatomy he was a master builder—not an architect.

For over sixty years he issued some four or five papers annually—some small, others great, but always replete with first-hand observation. A survey of his scientific career shows that he followed the normal course of our greatest workers; he spent the latter two-thirds of his active career in completing conceptions he had formed in the opening third. In 1862 he fell, as Knox and Goodsir had done before him, a victim to the structural fascination of whales; only three years ago he compiled, completed, and published an excellent and richly-illustrated catalogue of his whale collection under the title of *The Marine Mammals in the Anatomical Museum of the University of Edinburgh*. In 1866 appeared his first work

on the brain; for twenty years the brain formed one of his chief studies. He began a study of the comparative anatomy of the placenta in 1871; he made placentation a chief subject for investigation for nearly a score of years. If we set out now to make inquiries on any of these subjects, we can be certain of getting help and accurately observed data from his papers, and our successors for many generations will have reason to bless him. He had an unbounded capacity for work and for taking pains, and the most marvellous aspect of the whole of his career was his ability to combine a life of extraordinary scientific industry with one laden with administrative duties—sufficient to tax the whole time and strength of most men. He was that rare combination—a statesman and a researcher. He was for fifty years the outstanding figure in British anatomy.

Turner as a Teacher.

Dr. ARTHUR THOMSON, Professor of Human Anatomy in the University of Oxford, writes:

Sir William was one of the ablest men I have ever known. That is high praise. I lay no claim for him of outstanding genius, but for sheer ability I have not met his equal.

He combined, in a remarkable degree, high attainments in science with unusual business capacity, a blend which, despite the recent correspondence in the press, is oftentimes remarkably scarce. He possessed, too, a shrewd knowledge of men, a keen sense of justice, and an appreciation of the subtleties of diplomacy. In finance his views were sound, if somewhat conservative. There was nothing speculative in his policy, he would take no risks, but when occasion arose he would back his opinion.

It is of him as a teacher, however, that you have asked me to write. That takes me back a long time—to the winter of 1875—but after forty years, the memory remains as fresh as if the incidents had happened yesterday. I confess at the time of my first introduction to the anatomical department I did not know whether I was most impressed with the vigorous personality of the professor or the uncouth appearance of the gigantic James, the dissecting-room porter.

To us boys, university professors were as gods, impersonal and beyond reproach, awe-inspiring and all-powerful. There were exceptions, of course, men, brilliant though they were, unable to control the exuberant spirits of their pupils. Turner was not one of these. When his voice was heard, as he entered the dissecting-room, all was stilled, and every one endeavoured to display an unwonted interest in his work. There was never any rowdy element in his class; if some adventurous spirits were courageous enough to attempt an interruption the disturbance was soon quelled. The method was simple but effective. The professor stopped abruptly in the middle of a sentence, concentrating his gaze—a not altogether pleasant gaze either—on or in the neighbourhood of the offenders, and thus waited till the noise stopped. He had not long to wait, for I never yet met the man who could withstand that stare; then when silence was restored, the professor finished his sentence without further comment, and proceeded with his lecture. That was my first lesson in the discipline and control of a class—Look very fierce, keep perfectly calm, and say nothing.

It was, perhaps, as a demonstrator that the professor was most successful. In those days the class met at 4 o'clock—a sleepy hour; but despite this, he kept the interest of the men awake and keen. I have often heard it said what a wonderful thing it was that Turner could lecture, for an hour on end, on the superficial fascia of the thigh; it was not mere “word slinging,” but a carefully elaborated description devised to bring out the salient points.

His teaching was dominated by a sound perspective. The main features were emphasized by repetition and appropriate reference to points of practical and scientific interest, whilst the details were not unduly enforced. In this way the student carried away an effective and useful impression of the subject treated. In my opinion, the virtue of this method has been too much lost sight of in these latter days, and now the student very often cannot “see the wood for the trees,” a criticism which applies equally to the modern textbook descriptions as well as to the oral instruction.

As illustrating this aspect of Turner's teaching, a story is told, the authenticity of which I cannot vouch for.

Photo.

Mount.

SIR WILLIAM TURNER, K.C.B., F.R.S.

Goodsir, it appears, was in search of a demonstrator, and, happening to be in London, called on Paget to see if he had any promising pupil. Young Turner was introduced, and, being requested by the great anatomist to give a sample of his capacity by demonstrating the sartorius muscle, the nervous youth at once proceeded: "The sartorius, the longest muscle in the body, takes its . . ." "That will do," interrupted Goodsir, and promptly gave him the post.

As a lecturer he was remarkably illuminating, particularly when dealing with some abstruse point, but the ordinary undergraduate never saw him at his best, for he was handicapped by having to cover the whole subject of anatomy in the course of a hundred lectures. None the less, the summary which he presented to his pupils, and of which I still retain the notes, was most skilfully drawn up, and of extreme value from a didactic point of view. His lectures were prepared with great care, and it was this which brought me first into more intimate contact with him, because, as a student, I was frequently requisitioned to prepare the diagrams necessary to illustrate new points. Hitherto I had known only the official side of the man; now I had opportunities of making acquaintance with the softer side of his nature. My subsequent association with him for five years as one of his assistants enabled me more fully to appreciate his virtues as a master, and kindness as a friend. What particularly impressed me was his thoroughness: no labour was too arduous, if only it revealed the truth. He possessed the infinite capacity for taking pains which resulted in the accumulation of that great store of valuable research which now stands to his credit.

Most men are content to exhaust the fruits of their originality by middle age; Turner continued to the last to retain his interest in research, and that too at a time when his duties as Principal and Vice-Chancellor might reasonably have been regarded as sufficient to tax the energies of a man less capable and strong. He regarded research as a relaxation from the tedium of office work, and his last paper on "The craniology of the people of Scotland," published in the *Transactions of the Royal Society of Edinburgh* for November, 1915, reveals no weakening of effort or performance—a remarkable feat for a man over 84 years of age.

Those only who knew Sir William intimately can estimate the worth of the man. His affection for his university was an outstanding feature. The land of his adoption never had a stouter champion, and colleagues and pupils never a truer friend, but what perhaps we, who knew him well, realized more than most, was that love of home and family which stirred his heart. To us, too, was revealed that hidden fund of humour which few acquainted with him suspected. No doubt to these traits in his character is due the success which he attained in enlisting the sympathy of wealthy benefactors to his university. For this alone he has earned widespread recognition and gratitude.

To me, who have enjoyed his ever-helpful friendship and almost fatherly affection, the loss is sore and grievous, yet tempered with the satisfaction that he has fought the good fight, that he has left a record which few can equal, and that now he is at rest.

Dr. ARTHUR ROBINSON, now Professor of Anatomy in the University of Edinburgh, writes:

Sir William Turner was associated with the anatomy department of the University of Edinburgh for a little over sixty-one years—thirteen years as chief assistant, thirty-six years as professor of anatomy, and for the remainder of the period, up to within three weeks of his death, whenever he could find opportunity amidst his multifarious duties, he continued his anatomical research upon cetacea and in craniology. Indeed, there is still set apart, in the small private workroom reserved for him in the anatomy department, a series of New Guinea skulls which he proposed to investigate and report upon.

The anatomy department, as it stands to day, was his creation. It was built under his supervision, whilst he was professor of anatomy, and is a visible illustration of his grasp of the necessities of his subject and of his foresight for its advance, for when the department was built it was a great improvement upon anything which had preceded it, and it still holds a high place for its utility and adaptability. In it and in the old buildings, now given

over mainly to arts and science, he carried out his numerous and varied investigations with the care, exactitude, and insight which characterized all his work, and placed it on the highest plane; but to those who were fortunate enough to be his pupils, it is not so much the greatness of his life-work and the admiration which it has excited which appeal to them, but rather his character as a teacher, controller, and a man.

His lucid expositions made the most difficult subjects simple; his knowledge of comparative anatomy gave a charm to details of human anatomy which might, without the association, have seemed dry and uninteresting; and the stern discipline which he enforced in his department produced energetic and faithful work. The sternness was, however, largely superficial; beneath it there lay a very human interest in and sympathy for every one who passed through his hands. His complete knowledge of all his students was not the least of his many remarkable characteristics, and he was always ready with advice and help for any one who desired the one or deserved the other. He detested carelessness, but he admired and encouraged work; in fact, he gloried in work, and one of the secrets of his success, which he retained to the last, was a youthful enthusiasm for work, not only as an administrator but also in investigations on the subject which had occupied the greater part of his life; and whilst he worked he gained the respect and esteem of all who were associated with him.

The General Medical Council.

We are indebted to Sir DONALD MACALISTER, K.C.B., who succeeded Sir William Turner as President of the General Medical Council, for the following note:

When I joined the Medical Council in 1889 Sir William Turner had already been a member for thirteen years. He had served from 1873 to 1883 as representative of the Universities of Edinburgh and Aberdeen, and after an interval of three years, when the joint seat was occupied by Sir John Struthers, he had been returned as representative of the University of Edinburgh under the Medical Act of 1886, and he continued in office till his resignation in 1905. His intimate knowledge of medical legislation, in the shaping of which he had borne an active part, his scientific eminence as an anatomist, and his force of character as a man, gave him a strong position in the Council. His contributions to our discussions were always clear, emphatic, and weighty. Many important decisions were taken on his initiative, either in Council or in Committee. Many of our most valuable reports were drafted or re-fashioned by his hand. On matters of medical education, particularly as it is apprehended in Scotland, his authority was admitted. Though his birth and training were English, he approached educational questions from the Scottish point of view, and he harboured no doubts as to its excellence. He was in the succession of the great teachers who had brought the Edinburgh school to the height of its expansion and of its fame, and he gave their due value to its characteristic methods and aims. Other ways might be favoured in the South, but he had misgivings about them; and he often confessed to a certain perplexity in judging of their intrinsic merits. In some respects he had become *Scotis ipsis Scotior*. In our judicial inquiries he was notably free from hastiness or prejudice. He weighed the evidence for and against a practitioner with candour and caution; and though jealous for the corporate honour of the profession, he took full account of what might be said in extenuation of individual offences against it. He possessed the "judicial mind." As a junior member I have often heard my seniors, during an informal discussion of some difficult case, ask one another: "Do you know what Turner thinks about it?"

It was, therefore, not surprising that when the Presidency was vacant through the death of Sir Richard Quain in 1898, Sir William Turner was by common consent called to the chair of the Council. From 1858 onwards his predecessors had all been chosen from the English branch. He was the first President from beyond the Tweed. His position was not always easy. The finances of the Council were not satisfactory. There were thorny questions, personal and professional, that called for careful handling. Criticism of the Council and its officers was free and not always friendly. Reforms of procedure and administration had to be carried through in

the face of opposition that was not readily conciliated. But the President's manifest fairness and firmness, his grasp of executive detail, and his power of evoking loyal support, enabled him to win through. And when he resigned the chair in November, 1904, the members spontaneously offered him the tribute of their grateful esteem at a banquet which will long be remembered by those who were privileged to be present.

It was at the special request of myself, his successor in the chair, that he continued for nearly a year to retain office as an ordinary member of the Council. I was anxious that we might not at once lose the benefit of our Nestor's wisdom and experience. In other hands than his the situation might have been awkward, but his tact, good feeling, and surety of judgement never failed. The new President and the Council as a whole profited greatly by the counsel and the active helpfulness of the President Emeritus, and when at last he retired, on the ground that he had reached his seventy-fourth year and needed rest, he carried with him the loyal affection and regard of all his colleagues.

The University.

Sir LUDOVIC J. GRANT, Bt., LL.D., Professor of Public Law in the University of Edinburgh, Secretary to the *Senatus Academicus*, writes:

I willingly accede to your request that I should write a few lines in appreciation of the great leader whose loss all here are now deeply mourning.

The influence—so wise and so beneficent—which Sir William Turner exercised over the affairs of the University of Edinburgh must not be measured by the comparatively brief period of his reign as Principal. He was an active force in academic administration *Consule Planco*—in the Seventies and even in the Sixties. Engrossing as the duties were which devolved upon him as professor of anatomy—namely, the systematic instruction of the largest class in the university and constant attendance in the dissecting-room—"Turner's Conservatory," as Sir Alexander Grant nicknamed it—he nevertheless found time to make himself a thorough master of university business, especially on its financial side. Long, then, before he was actually installed as Principal, he had become a moving spirit, one of the most vital and kinetic elements, in that mysterious entity known as "The University Authorities." It is this that makes it so difficult—for the older members of the *Senatus*, at any rate—to imagine what the university will be like without Sir William Turner.

It was characteristic of the late Principal, and indicative of his superabundant energy and earnestness of purpose, that even his relaxations were serious. Unconsciously, he directed his own life in accordance with the precepts of the old Scots ordinances which, in the interests of archery, forbade young men to devote themselves to golf and football. So long as bodily activity remained with him he took his recreation chiefly in the form of volunteering, and it is common knowledge how enthusiastic and efficient an officer he proved himself, and how magnificently he trained the University Company of the Q.E.R.V.B. For ordinary games he had no taste. This, however, does not mean that he disapproved of them, still less that he discouraged them. He was fully alive to the importance of furnishing students with opportunities of athletic exercise in all forms.

Nothing, moreover, could be more misleading than to represent the late Principal as solemn or austere. With his high sense of the responsibilities of life and of the importance of work, and his intense devotion to duty, he combined a most genial disposition, a delightful bonhomie, and abundant humour. These lighter attributes were seen, perhaps, to their best advantage when he presided at "Symposia Academica" or at the dinners which he was in the habit of giving on the night preceding graduation ceremonies for the benefit of those who were to receive honorary degrees. He entered *con amore* into the spirit of such occasions, and it was delightful to witness the enjoyment which he himself derived from them.

Those of us who were privileged to come into daily contact with him have suffered by his death an immeasurable loss. He was so considerate, so helpful, so willing to spare trouble to others, and so unsparing of himself.

Some Reminiscences.

The following is from Sir A. R. SIMPSON, who was apprenticed to Professor Goodsir in 1852, and acted as class assistant to Dr. (afterwards Sir John) Struthers when in charge of the anatomical department in the university on the occasion of a threatened breakdown in the health of the professor:

In the autumn of 1854, when Goodsir returned from a year's rest in the Riviera, he brought with him from London three young surgeons to be his demonstrators. They were obtained respectively from his friends Professor Sharpey of University College, Sir William Fergusson of King's, and Sir James Paget of St. Bartholomew's Hospital. Frederick W. Sayer, who was spoken of in glowing terms by Dr. Carpenter, died of fever after a short period of service here. A. M. Edwards was more surgeon than anatomist, and, after serving for a few years in the dissecting-rooms, entered on a brilliant surgical career in Edinburgh that ended obscurely in Australia.

Chief of the three was William Turner. From the first Paget's pupil seemed to grasp the opportunities of the new position and to be grasped by them. They favoured the development of those fine qualities that by-and-by were to be exercised in the higher spheres of the professoriate and principalship so as to win for him the admiration and affection of thousands of students, and of all his colleagues in the *Senatus*, the University Court, and the Court of Curators, and to enable him to render services that will make his name indelible in the story of our university. Foremost among the influences that went to the making of him was the personal influence of John Goodsir. He clearly brought with him from his home great natural abilities and a well-directed disposition which had been fostered through his friendship with Sir James Paget, that great surgeon and good man who has left an inspiring memory for our profession. But with Goodsir his demonstrator's intimacy was to be closer and more prolonged. Even in attitudes and actions Turner unconsciously assimilated some of his master's peculiarities. If any one recalls that some time in talking with him as professor or principal he felt himself touched on the left shoulder, he may know that he was only experiencing what Turner had often experienced. For Goodsir had a trick of shooting out the right forefinger to impress on an assistant any duty he was entrusting to him or fact of science he sought to enforce. What was more important for the young Englishman was that he began early to take colour from his new master in his habits of clear conception of duty, his untiring industry, his delight in pure scientific research, and his firm apprehension of the spiritual aspect of the universe. I refer especially to this last element in the make-up of my friend, for other points in his impressive character and career will be abundantly illustrated by other pens.

The works of Goodsir, edited by Turner, are marked by a patient, serious search for truth, and where need arises, in the presence of the mysterious, by a reverent acknowledgement of the Divine, for he did not dally with agnosticism. The same mind is found in the works of his successor. It may be felt in his address from the chair of the British Association, a position from which the "promise and potency" of mere matter had been so frequently proclaimed. Still more, if he had to address his students on their graduation day, the man who could give the shrewdest advice as to their outlook on life, would remind them that "wisdom is the principal thing," and tell them where to seek it. So, also, if he read the Scripture lesson in some university function, or took the chair at one of Dr. Kelman's Sunday evening meetings arranged by the Christian Union in the Operetta House, the men could recognize in his voice a ring of reality that helped them to feel that the service was not mere routine. When we once came out together from one of Professor Henry Drummond's meetings with students in the Odd-fellows' Hall, after discussing the man and his message, Turner said: "After all, that's just what I'm always trying to teach the men."

About three years ago I sent him a reprint of a paper from the *Expositor* upholding the scientific view of Dr. Stroud as to the physical cause of the death of Christ. He sent me a long typograph in reply, strongly endorsing from his own pathological observation and reflection

the theory of the broken heart, and adding some criticisms as to the testimony drawn from the works of artists. The editor of the journal was prepared to publish the letter, and Turner consented, but first asked it back as he wanted to make some further investigations among the great paintings with the help of his friend, the Rev. Dr. Gordon Gray, in Rome. About a year ago I pressed him to publish his observations, which he said he was quite willing to do, but was still waiting for the collaboration of Dr. Gray. It must have been at that same call on him that he spoke of an article in the new Y.M.C.A. magazine on "Surgical assuagements of war," in which it was indicated that some of the men to whom the world was indebted in this direction were confessedly Christian men. Among these necessarily was the name of Lord Lister. Now Lister came to Edinburgh only a couple of months or so after Turner. The two young men drew together and became fellow-workers and fast friends. I do not know that I ever saw Turner exhibit more emotion than on that occasion when, referring to his old colleague, he said, "I have a place where I keep memorials of Lister, and I have put the little article among them."

John Goodsir, James Paget, Joseph Lister are shining names in the firmament of science. The three each laid their crown at the feet of Christ. William Turner was a kindred spirit.

DR. FRANCIS GETHIN HOPKINS, late P.M.O. Gold Coast Colony, died at Plymouth on February 2nd, while serving as Lieutenant R.A.M.C. He was in his fiftieth year, and was the son of the late Rev. J. W. Hopkins of Aherm, Fermoy. He graduated B.A., T.C.D., and took the M.B., B.Ch. (1888), and the M.D. (1903). After some years as resident to the City Fever Hospital and the Brownlow Hill Infirmary, Liverpool, he entered the West African Colonial Medical Service in 1894. He served with the Anglo-French Boundary Commission between Dahomey and the old Colony of Lagos, and was promoted senior assistant colonial surgeon, Lagos, in 1897. He became senior medical officer on the formation of the West African Medical Staff in 1902, was promoted Deputy P.M.O. on the amalgamation of S. Nigeria and Lagos in 1906, and P.M.O. Gold Coast in 1911. For many years he was M.O.H. Lagos, and also a member of the Executive and Legislative Councils, Gold Coast. During his administration of the Medical Department of the Gold Coast Colony the scope of his activities was widely extended by the development of the sanitary branch, and no small share in the improvement in health conditions must be attributed to the department over which Dr. Hopkins has presided. He was instrumental in obtaining provision of pensions to widows of men in the W. A. medical staff. Dr. Hopkins was a Freemason and helped to found two lodges and a chapter in West Africa. Dr. Hopkins's career in the West African Medical Staff was characterized by serious and energetic work, and he was held in high esteem by natives and Europeans. On his return home in September last he accepted a commission as Lieutenant in the R.A.M.C. and was appointed Medical Officer-in-Charge Troop Citadel Barracks, Plymouth. On January 27th he developed pneumonia, probably post-influenzal, and died on February 2nd. The funeral, which took place at the New Cemetery, Plymouth, was attended by full military honours. Dr. Hopkins leaves a widow and four children. A friend of more than thirty years writes that Dr. Hopkins, though a man with high ideals of and devotion to his work, was also a keen sportsman. He was an expert fly fisher and a good shot. It is, he adds, sad to think that after a strenuous career of working for his country he has been taken away when he might reasonably have hoped for many more years of useful and active life.

SURGEON-MAJOR FREDERICK CARTER, Bengal Medical Service (retired), died at Wearden Ash, Ongar, on January 24th, aged 85. He was born on March 20th, 1830, took the diploma of M.R.C.S. in 1832, and entered the I.M.S. as assistant surgeon on August 4th, 1855, becoming surgeon on August 4th, 1867, and surgeon-major on July 1st, 1873. He retired on April 25th, 1887. He served in the Indian Mutiny with the 17th Light Field Battery, Bengal Horse Artillery, and with the Punjab movable column under Brigadier-General Nicholson, and received the Mutiny medal.

Medical News.

SIR JOHN ROSE BRADFORD, K.C.M.G., C.B., M.D., F.R.C.P., Colonel A.M.S., has been elected President of the London and Counties Medical Protection Society, Limited, in place of the late Dr. George Allan Heron.

PROFESSOR WEINBERG, Chef de Laboratoire, Institut Pasteur, Paris, will give a Dr. James Finlayson lecture in the hall of the Royal Faculty of Physicians and Surgeons of Glasgow (242, St. Vincent Street) on Tuesday next at 4.30 p.m. The subject will be gas gangrene, and all medical practitioners are invited to attend.

A NATIONAL congress on home problems after the war is being arranged by the National Housing and Town Planning Council, to consider the preparation of housing schemes for the building of urban and rural cottages, and the need for Government aid in the preparation by local authorities of schemes for the clearance of insanitary areas. It hopes to assist in the preparation of town planning schemes in anticipation of future developments. The congress will be held in London from April 11th to 14th. Further particulars can be obtained on application to the secretary at 41, Russell Square, London, W.C.

MEETINGS of the Central Midwives Board were held on February 17th and 18th for hearing penal charges. Sir Francis Champneys presided. The reports on four out of six adjourned cases were satisfactory, and the other two were again adjourned for a month. Twelve fresh cases were heard, and in four instances the women were struck off. Judgement was postponed in three cases; three other women were censured, one case was dismissed, and the remaining one concerned an old woman of 81, whose resignation the Board accepted. Allegations of neglect in respect of ophthalmia, rupture of the perineum, and delayed labour were among the charges. One woman, it was alleged, in a case of twins of which one was still-born and the other died before the arrival of a doctor, herself took the bodies to the cemetery in a cardboard box and buried them in a hole 6 in. deep. The monthly meeting was held on February 16th. The Standing Committee reported a letter from the Town Clerk of Rotherham with reference to an apparent case of "covering" of an uncertified woman by a local practitioner, and asked the Board to make the necessary representations on the subject to the General Medical Council. The secretary was instructed to take the necessary steps. The names of sixteen women were removed from the roll on their own application. The chairman reported that arrangements had been made for temporary accommodation during the completion of the new offices.

As chairman of the board of governors, Dr. Edwin Rayner, J.P., Treasurer of the British Medical Association, presided at the opening of the fine new buildings of the Stockport Grammar School erected to replace those opened in 1832, which had become too small. Dr. Rayner recalled the history of the foundation of the school in 1487 under the will of Sir Edmund Shaa, some time Lord Mayor of London, who was born at Dukinfield, near Stalybridge; he left certain land in the City of London to the Goldsmiths' Company, the proceeds of which partly paid for the upkeep of the school to this day. Colonel Dixon, chairman of the Cheshire County Council, in declaring the building open, said that there were only two other public schools in the country which had more ancient foundations—Winchester (1387), and Eton (1441). The school was transferred by the Goldsmiths' Company to the Corporation in 1860, and had been enlarged from time to time. In proposing a vote of thanks to the chairman, Canon Bird said that not only Stockport, but the whole of Cheshire, knew the great educational work Dr. Rayner had done. He recalled the fact that Dr. Rayner had himself been a boy at the Stockport Grammar School; his interest in it had continued to the present day. Sir Thomas Holland, in seconding, congratulated the governors on the great growth of the school. Dr. Rayner, in acknowledging the vote, said it was the duty of the community to afford to every responsible man an opportunity of becoming a good citizen, and to teach the duties of citizenship would be, he hoped, one of the principal objects of the school. The new buildings contain a fine Hallam assembly hall, called after the Mayor of Stockport in 1860; a Sykes lecture room, named after a former chairman of the governors and a generous benefactor; a manual training room, fitted with benches; and a Norris gymnasium, named after two old boys and benefactors.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 423, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitology, Westrand, London*; telephone, 2531, Gerrard. (2) **FINANCIAL SECRETARY AND BUSINESS MANAGER** (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) **MEDICAL SECRETARY**, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the *British Medical Association* is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

ANSWERS.

NASCENT IODINE IN PHTHISIS.

IN reply to a correspondent in India, who asks for information on the subject, we may say that Dr. E. G. Reeve administers a dose of 20 (once he gave 30) grains of potassium iodide in half a pint of water at breakfast time, and an ounce of chlorine water in half a pint of lemonade four hours later, the draught being repeated at two hours' interval until sufficient has been given. In starting, three ounces of chlorine are administered daily. Signs of iodism usually develop, but are soon relieved. At the end of three weeks the dose of chlorine water is increased to four, and later to five ounces. The chlorine water must be very carefully prepared by the action of 2 drachms of strong hydrochloric acid on a drachm of powdered potassium chlorate in a dry 24 oz. bottle.

LETTERS, NOTES, ETC.

THE Central Committee for National Patriotic Organizations, of which Mr. Henry Cust is chairman, and Sir William Grey-Wilson, K.C.M.G., secretary, has issued a report on its work from its institution in August, 1914, to the end of January, 1916. Its object, which was strongly commended to the country by Mr. Asquith, Lord Rosebery, and Mr. Balfour in November, 1914, is mainly to disseminate information at home and in neutral countries. It has not, for want of funds, been able to undertake any systematic explanation of the British position in the newspaper press of foreign countries, but it has distributed much printed information to the universities and libraries in the various countries, as well as to influential politicians and teachers. It appeals for further assistance in money and in personal service, particularly by way of communications to foreign friends. Its offices are at 62, Charing Cross, London, S.W.

PETROL DUTY.

F. E. G. inquires as to a rebate on the petrol consumed in the professional use of his motor cycle.

* * The Act of Parliament refers to "motor cars" only, but a refusal to apply the rebate to motor cycles would be inequitable and uneconomic. In a case which was brought to our notice some time ago the rebate was at first withheld but granted on reconsideration.

INCOMPATIBILITY.

DR. H. DRINKWATER sends us a copy of a note he published in the *Liverpool Medico-Chirurgical Journal* (July, 1911), in which he said that for the previous fifteen years he had found a mixture containing sodium salicylate and liquor ferri perchloridi useful in rheumatic conditions associated with anaemia, and especially in a kind of sore throat with slight redness of the pharynx, and pain, especially on swallowing, which he believed to be rheumatic. He gives the following directions for making the mixture:

For an 8 oz. bottle, take 1 drachm of sodae salicylas dissolved in about 2 oz. of water. Add liquor ferri perchloridi, half a drachm + about an ounce of water. This produces a dark purple mixture, with a precipitate, thick and curdy in proportion to the concentration of the mixture. Then add 1 drachm of potass. bicarb. dissolved in 1 oz. of water, and fill up to 8 oz. with water. The precipitate dissolves on the addition of the potassium solution, and the result is a clear, claret-coloured mixture of an agreeable taste. The colour is lighter still if a little more potash be added.

Theoretically, 218 grains of sodae salicylas is equivalent to the iron in 1 fluid ounce of the liq. ferri perchlor., but *practically* only about one-quarter of this amount of iron can be used. If more liq. ferri is used than in the above prescription, there will be an active effervescence on the addition of the bicarbonate. With the above quantities there is no effervescence. (Of course, it would not do to mix the iron and the bicarbonate *before* adding the salicylate.)

THE PROPHYLAXIS OF DENTAL AND GINGIVAL SEPSIS.

MR. G. S. THOMPSON, F.R.C.S.Eng. (Sydney, Australia) writes: Having good teeth myself, and having given a good deal of thought, reading, and trial to methods for dental conservation, I would like to urge for adoption, amongst other things, a very simple but most effectual method for preventing food deposition on and consequent decomposition in and around the teeth. I am inclined to think that the too frequent use (that is, after every meal) of the toothbrush—especially if hard—is irritating to the gums, and may tend to lower their resistance and favour infection (pyorrhoea). I have reduced this part of the toilet to once a day following the last meal, and during the course of the meal the fluid taken before being swallowed should be vigorously moved backwards and forwards, from side to side, up and down in the mouth, thus passing over and between the teeth and washing off immediately any food deposited thereon. This is not really objectionable, as will be seen after a moment's thought, but it is highly objectionable to allow food (particularly the soft sticky kind) to collect, to render its removal much more difficult, become putrid, and set up inflammation. The food, if washed off at once, is fresh, like that swallowed, and the prejudice is merely a sentimental one that would disappear if the practice became general. For meat, etc., firmly wedged between the teeth, the ordinary method of removal by toothpick and thread will satisfy. I can state from experience that meal lavage as above keeps the teeth cleaner than by any other method I know. To prevent harmful friction on the gum I place the brush in half a glass of boiling water to soften bristles, take out and apply dentifrice, and fill glass with cold water. Movement should be up and down at first, then laterally. Thus with meal lavage, toothbrush after last meal at night, toothpick and thread, I think we have a potent means of averting dental sepsis, or rather of attaining oral hygiene.

THE IMMEDIATE TREATMENT OF SEVERE POST-PARTUM HAEMORRHAGE.

DR. ALEXANDER BROWN (London, N.W.) writes: Evidently Mr. R. K. Howat did not read an impressive article in the *Lancet* on this very subject, some ten to fifteen years ago, by the late Mr. Stanmore Bishop (Mr. Stanmore Bishop's article was published in the *Lancet* of 1901, vol. 1, p. 1069). There the lamented surgeon criticized in a very able fashion the "encyclopaedic list" of remedies; pointed out how the employment of first one remedy, then another, and yet one more, often found the patient dead before the next could be attempted; and then proceeded clearly to lay down that the principles governing the arrest of haemorrhage in, for example, a limb, were equally applicable in haemorrhage from the uterus—namely, elevation and compression at the nearest "pressure point"—the abdominal aorta. At the time, I remember, I looked up the matter in one or two textbooks, and noted how flabby and unconvincing their teachings were, and how unfavourably they compared with the inexorable logic and explicit directions of Mr. Bishop's article. Accordingly I adopted the latter's precepts, and in the few severe cases of post-partum haemorrhage I have since had have always followed them—with success, I am glad to say. It is truly extraordinary to hear from Mr. Howat that obstetricians and textbooks have not mended their old ways in this respect, and Mr. Howat is to be congratulated on once more insisting on a clear course of treatment in the great emergency of post-partum haemorrhage.

DR. J. FARQUHAR (New Romney) writes: "In conversation every one found the suggestion a novelty"—concludes the author of an able article on the subject in your impression of February 5th, p. 193. Well, there is nothing new under the sun. Forty years ago I had seen or heard the method advocated of raising the bleeding area, and can easily remember standing on the bed and raising a rather flaccid multipara in dire straits, feet in air and head hanging downwards, but not using the additions recommended by Mr. Howat. Success was immediate and lasting. I can also remember another way I used. In a very cold house in an exceptionally hard winter season in the West Riding I met with a case of this description. After douching the uterus freely with very hot water, I gave by the mouth about a quart of very hot gruel with a similar happy result. Ergot I had not found very reliable in junctures of this sort.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

An Address

ON

THE TREATMENT OF GUNSHOT WOUNDS.*

By SIR BERKELEY MOYNIHAN, M.S., F.R.C.S.,

LIEUTENANT-COLONEL R.A.M.C.;

CONSULTANT SURGEON, NORTHERN COMMAND.

The problem of the treatment of gunshot wounds has been profoundly modified, if indeed it has not been radically altered, by the knowledge gained during the present war. Neither the civil experience of the last forty years, nor any recent military experience, had prepared us for the kind of work which from the very outbreak of the campaign it was our duty, as surgeons, to perform. The new and unexpected things which occurred were due to a set of circumstances each one of which was in some degree different from anything we had observed before. The character of the missiles in respect of the mode of flight and velocity was not that with which former wars had made us familiar. The damage inflicted upon the tissues was far greater than and different in quality from that commonly seen in South Africa; the organisms carried into the wound from the surface of the body, from the earth around, or by fragments of clothing, judged by their clinical results, transcended in virulence or in fecundity anything known by the present generation of surgeons; and, finally, the soldier, in the earlier months of the war at least, had undergone so serious and prolonged a strain, before being wounded, that he often fell an easy victim to a bacterial onslaught of great ferocity. The efforts of the surgeons to deal with the wounds so grievously infected were at first lamentably inefficient. Suppuration surpassing in profusion or in malignity anything we had seen before occurred in the majority of cases, and the efforts which our civil experience suggested as the most helpful did very little to check the activity of the process. Failures were spoken of, the failure of the antiseptic system, the futility of aseptic methods, and Lord Lister's immortal work was belittled or held of no account. One of the first tasks I set myself on returning from France early in 1915 was to read again Lord Lister's papers with the new knowledge I had gained on foreign service to help me to a better understanding of the problems with which he had to deal fifty years ago. All that Lister wrote can be read with great advantage to-day. The essential problem he confronted and conquered is that which we have still to meet, and the principles he laid down are as strictly applicable now as they ever were. Lister clearly distinguished the difference between the prophylactic and the therapeutic value of antiseptics; he emphasized the all-importance of the former, and pointed out the inadequacy of the latter. The work of surgeons, since Lister taught, has depended for its almost incredible success upon the prevention of infection in wounds deliberately inflicted; not upon the control of an infection already established. This by comparison is a trivial matter. Lister, however, needs no defence, and if he did, none more eloquent and unanswerable could be written than that which is found in his own papers.

What, then, were the several new factors that had to be considered in this war?

In the early days a very large number of the wounds were inflicted by rifle fire. The German bullet has a muzzle velocity of approximately 1,000 yards per second. In the first 800 yards, or thereabouts, the flight of the bullet is not steady but "wobbling." There are three movements—a movement forward along the line of flight; a rotatory movement, in which the bullet spins round on its longitudinal axis as a result of the "rifling" of the barrel; and a third movement, a "mouvement de bascule" of such a character that while the point of the bullet keeps steady the base of the bullet is moving round a circle, or an ellipse, of a gradually diminishing size. The result of this last form of motion is this, that when the bullet impinges upon any substance, even the soft clothing or the flesh,

the infinitely brief arrest in the point which strikes first allows the base, which is, of course, much heavier, to overtake the apex, and the bullet then lies sideways, or begins to turn over and over as it ploughs its way through the soft parts. In this early part of its trajectory the missile has, of course, a great momentum; it is a heavy bullet, travelling with great velocity. The consequence is that the damage inflicted is not confined to the track it rudely makes through the limb; the parts around the track are damaged also, often to a great extent. Every wound, therefore, caused by a bullet at short range, consists not only in a visible tearing and destruction along the path the bullet has followed, but in a dead zone everywhere surrounding that track—a zone in which death and destruction or disintegration of the parts has occurred by reason of the tremendous concussion produced by the bullet as it tore its way clumsily through the tissues. Sir Anthony Bowlby has proved this by a series of exemplary instances. In one of these the kidney was wounded in its lower pole; the upper pole appeared normal to the naked eye, yet on microscopic examination the tubules were seen to be disorganized. Other examples of the widespread damage inflicted are quoted in his Bradshaw lecture. And even that is not all. The momentum of the bullet is such that to everything it encounters it imparts some of its own velocity. As we all know, shreds of the clothing or belt, or the contents of the pocket, may be carried deeply into a wound. So also are pieces of skin or muscle. And if the bullet should chance to strike a bone, the bone is not only broken into many fragments, the "splinter" fracture, but to all fragments there is conveyed enough of the momentum of the bullet to convert them into projectiles also, capable of tearing a way into the softer tissues. Many of the wounds, therefore, were deep, irregular in shape, with large or small cavities; of the variety the French term "anfractuans." Into these recesses blood escapes, and owing to the tearing and unequal retraction of cut muscles, pools of fluid may be shut off from the main track of the wound.

If a rifle bullet is not checked in the first 500 yards of its flight it begins to steady down, and probably when it has travelled 1,000 yards it is moving evenly. An injury inflicted then is of a quite different character. The bullet cleaves its way through the soft parts, bores a neat hole through a bone, and little destruction is done. We see many cases where the chest or abdomen are traversed from side to side, or where the neck has been pierced, and, miraculously, no real damage has been done. Examples of this form of injury were of course common enough in the South African war. They have been less frequent in this war because the range has often been shorter, and the bullet in respect of velocity and weight is different.

The campaign in Flanders and in Northern France has been conducted on fields many of which have been as highly cultivated, and were therefore as heavily manured, as any in Europe. Generations of husbandmen have earned their livelihood from this earth, and it has therefore been necessary to enrich the soil by applications of manure—the faecal material of horses, cows, and pigs. The contact between the soldier and the soil upon which he fought has never been more intimate. The hands and faces, bodies and limbs, were grimy with the mud and dust that penetrated and clung to the clothing of these soldiers. And opportunities for the change of clothing were not frequent. In the earlier days of the war men were commonly a couple of months or more without the chance of taking off their trousers. They were literally covered from head to foot with clay and earth and mud. And this mud, largely manurial in origin, contained micro-organisms which, given the chance of growth in a fertile medium, proved luxuriant. They were the organisms of tetanus, the gas-gangrene bacillus (*Bacillus perfringens*, *Bacillus aerogenes capsulatus* of Welch), the *Bacillus coli*, putrefactive organisms of several forms, and a streptococcus which has since been recognized as the enterococcus of the French writers. All were of faecal origin. It was very interesting to find that while I was in France we rarely found the *Staphylococcus pyogenes aureus*, the common cause of suppuration in the wounds of civil practice at home. It was only at a late stage in the history of the cases that this organism invaded the parts.

In the early months of the war the soldier who was wounded was often wearied almost beyond endurance by

* Delivered at the opening of a discussion on the treatment of gunshot wounds at the Harveian Society of London, February 24th, 1916.

excessive exertion, loss of sleep, and unceasing anxiety and strain. When I had the opportunity of visiting field ambulances and some clearing stations I was struck with the condition of the patients on admission. As soon as a man reached shelter and quiet he fell asleep. Even during the dressing of his wounds he often slept heavily, and the temptation of hot soup or the inevitable cigarette could hardly persuade him to rouse himself for more than a few moments. Left to himself he fell asleep at once. Even at the base hospitals I have known men sleep for forty-eight hours with barely a movement, other than that grudgingly made to take a drink. When the wounds were serious, as in compound fractures of the thigh, the men were often collapsed, cold, and white, with feeble pulse and flickering breath. A part, no doubt, of this reduction of the patient's vitality to so low an ebb was due to the delay in bringing him to an aid post or a field ambulance after he had been wounded. But no organization in the world can alter this, for it does not depend upon us, but on the enemy. Little or no respect is paid to the Red Cross near the firing line, probably because it is not easily visible. A stretcher party bearing a wounded man is exposed to the fire of rifle or of shrapnel, if at any moment it allows itself to be seen. This is equally the rule at night also. It is only by stealth, and at opportune moments, that a wounded man can be taken away, and the delay in tending him, which is deeply regrettable, cannot be prevented.

Such, very briefly, are the conditions present when a man is wounded. The missile inflicts great damage along the track it follows; hollows and recesses, caused by the unequal retraction of torn muscles, are formed everywhere, and within them effused blood may be pent up. In all the parts round this bullet track the parts are dead, offer no resistance to the bacterial invasion, but rather form the most nutritive medium that could be desired for the propagation of bacterial life. Into every tiniest cavity micro-organisms may be carried with some degree of violence, and sown everywhere on a fertile soil. The micro-organisms themselves, if not always of the greatest malignity, proceed to develop with the most intense activity, finding all conditions most suitable. They are given time to make headway, because of the interval that needs must elapse before a careful dressing of the wound can be undertaken. And the victim of this injury is himself very often in a condition of such fatigue or general collapse as will reduce his power of resistance much below the normal. Nothing, of course, in any degree comparable to this condition of affairs is ever seen in civil practice, and when the methods of civil practices were brought to bear on such cases they very naturally failed to give the results which had been expected of them.

The treatment of gunshot wounds may, I think, concern itself with (1) the prevention or control of the infection in wounds at the earliest possible moment after their infliction; (2) the reduction or the abolition of the infection after this has once been fully established in the wound. Before these matters are discussed, however, there are certain first principles, applicable to all wounds, which may be stated once for all.

A.

Excision of the wound, if it can be practised, is, of course, an ideal method. Unhappily the great majority of the injuries inflicted are of such a kind that the wound surfaces are most irregular. This is partly due to the actual damage done by the bullet; partly, indeed chiefly, to the very unequal retraction of torn muscles. An accurate excision of the surfaces of an anfractuous wound is, therefore, hardly possible in the majority of cases. When, however, it can be done, it is certainly the most desirable, for the zone of the infection once cut away there remains only a clean wound, which may be closed completely by suture, and healing by first intention may be secured. Wounds of the scalp, penetrating wounds of the knee-joint, and wounds of the abdominal wall all lend themselves at times to this method of treatment. The technique must be scrupulous and exact, or the good results are jeopardized. Colonel Gray has advocated this method in suitable cases and speaks well of it.

B.

In all cases of large or penetrating wounds a thorough examination and preparation of the wound for its sub-

sequent dressings must be made. The administration of an anaesthetic is frequently necessary at the earliest opportune moment. A preliminary disinfection of the skin with some efficient antiseptic is clearly necessary. I regret to notice that iodine in some form or other is the favourite application. It is, of course, easy to use, and because of its colour it is easy to see whether, and to what extent, it has been applied. But its very simplicity is often a drawback, for we can never afford to forget that the ritual of surgery must on all occasions and at every moment be as scrupulous and exact as it is possible to make it. Perfunctory work at one period breeds laxity at others. It is not easy to sterilize the skin or to keep it sterile for half an hour by any method of preparation. I have more than once seen the tincture of iodine painted over a limb to which dry dung or earth was adhering. To believe in the efficacy of such methods is mere fetish worship. All the methods of iodine preparation of the skin are short of the best, and many of them are utterly inefficient. Abundant experimental evidence, which need not now be quoted, supports this contention, and a thorough trial by myself and others shows clearly that the quality of healing in operation wounds, when the skin has been prepared by any of the iodine methods, leaves something to desire. The cleansing of the skin is very important, because from organisms in the skin the wound may often be reinfected. This is more especially the case when the old form of civil dressing is used. This consists in applying a large amount of gauze, a mass, large or small, of wool, and finally bandages. When the discharges from a wound are free it is probably not many minutes before the gauze, with a layer of this wool, is soaked with them; until the next change of dressing the wound is then fomented with its own secretions, and the discharge infects the parts surrounding the wound. Unless, therefore, the skin is thoroughly cleansed afresh a new dressing is infected by it at the moment of application. The skin must be thoroughly cleansed, then, by ether soap, ether, benzine, petrol, or other efficient material, and an antiseptic liquid applied. Binioidide of mercury in spirit, Harrington's solution, Macdonald's solution, or Dakin's solution are the most effective. The latter, for the purposes of war, is to be preferred, for the subsequent irrigation and dressing of the wound may be carried out with the same preparation. After cleansing the skin adequate drainage must be secured. This may need the enlargement of wounds already existing, or the making of new openings into the large and irregular wound cavity. Whatever is necessary to secure full and free drainage must be ruthlessly done, since the necessity for the unimpeded escape of all wound discharges is paramount. If by any chance the *Bacillus perfringens* has obtained access to the wound the patient's limb or life will depend upon the sufficiency of the drainage. The wound is then carefully examined; any fragment of clothing or any missile felt at once, is removed; dead or soiled fragments of torn muscle are taken away; the whole wound is irrigated with the antiseptic solution which has been selected for the purpose, say Dakin's solution, and the parts are then immobilized and dressed.

C.

Immobilization of Wounded Parts.—I fear that far less attention than it merits has been given to the consideration of this subject. When a bone is broken splints are applied as a matter of course, and the parts, as far as possible, are immovably fixed. This is recognized as essential, not only because of the obvious diminution in the patient's suffering, but also because it is now well recognized that any form of movement in these war wounds aids appreciably the extension of the infection. It is not yet, I think, sufficiently realized that immobilization of wounds in the soft parts is equally essential. The comfort of the patient is sensibly increased, and the spread of infection is checked. Like every other useful measure, however, the immobilization of limbs can be misapplied. It is important to remember that fixation of legs or arms for an undue length of time may result in stiffened joints and withered muscles, and that months of painful passive movements and of massage may be needed to repair the errors of a few weeks.

1. THE PREVENTION OR CONTROL OF INFECTION IN GUNSHOT WOUNDS AT THE EARLIEST POSSIBLE MOMENT AFTER THEIR INFLECTION.

Shortly after the outbreak of the war the surgeons whose duties kept them at home were amazed at the severity of the infection in the wounds of soldiers returning from France. It was felt that adequate measures were not being taken to deal with these injuries. And discussions, both public and private, were frequent and not devoid of acrimony. Sterner measures were advised, the painting of all wounds with pure carbolic acid, or with tincture of iodine, which in the few years before the war had come again into favour among surgeons for many purposes. These various measures were indeed tried in France very thoroughly for a certain period. A large number of wounds were treated exclusively with pure carbolic acid, a certain number with tincture of iodine, others with simple field dressings. By the time the base hospitals were reached it was not possible to say what early measures had been tried. In all wounds suppuration was rampant, and the early and thorough applications even of pure carbolic acid were found not appreciably to alter the subsequent severity of infection. As we now look back upon that experience we realize, I think, that this failure was due, in part, to the feebleness of the antiseptics used. Pure carbolic acid, since Lister introduced it, has been taken as the standard of germicidal power. We have thought and spoken of pure carbolic acid as something of the greatest potency, all-conquering in its fight with germs. The truth is, of course, that, speaking comparatively, pure phenol is a very feeble antiseptic; and in contending with the organisms which had obtained a firm hold on the nutrient medium of these fresh wound surfaces it was little better than nothing. Its bactericidal power, always feeble, is much reduced when it is called upon to act in the presence of serum or pus; and when used in full strength it is apt to damage healthy tissues. It soon became evident, therefore, that if we were to fight with any chance of success against the particular type and degree of infection seen in the war, a few more powerful antiseptics must be discovered. It was here that Dr. Dakin came to our help. Dr. Dakin, an old student of the University of Leeds, had gone out to France early in 1915, with Dr. Alexis Carrel from the Rockefeller Institute in New York, for the purpose of carrying on medical research in a hospital attached to the French army. He had in mind various ideas as to the kind of antiseptic that might perhaps be used with success. One after another of these proved of little value, until finally a preparation was made from chloride of lime—bleaching powder. The details of the making of "hypochlorite" solution have been given by Dr. Dakin.¹ It has on examination proved to have a bactericidal value which is far higher than that of any antiseptic we have been accustomed to use. Pure carbolic acid, for example, will kill the *Staphylococcus aureus* in the presence of serum after acting for two hours when at a dilution of between 1 in 50 and 1 in 100. Dakin's solution acts in like circumstances at a dilution of 1 in 1,500 to 1 in 2,000. It possesses other qualities necessary in any germicide for use in conditions such as I have described. It is diffusible, it does not irritate unduly, it has a remarkable power of clearing away sloughs, it is easily obtainable, and it is very cheap. It has proved, in the hands both of the French and the British surgeons who have tried it, to retard or to prevent the development of sepsis more effectively than any other preparation that has been tried.

The preparation was first made at the University of Leeds by Professor Cohen to Dr. Dakin's formula, and I had therefore the earliest opportunity of acquainting myself with the virtues of the solution. I used it in cases of fresh and of old infection—in cases, for example, of compound fracture into joints where infective material had been introduced. In the cases in which the solution was used from the outset a powerful inhibitory effect was produced. Wounds healed as though no infection was present, and a thoroughly aseptic course was seen. In wounds where suppuration was already in full course very marked benefit was also seen, but of this I will speak later. It was quite evident, therefore, that in this "new antiseptic" a most powerful agent for good had been found. In several

cases, however, a moderate degree of irritation, especially of the skin, was seen. The degree of irritation seems to vary in different cases and in different districts. It may be that the bleaching powder from which the preparation is made is not always of the same quality. It may be, as Dr. Dakin suggests to me, that the solution, which has a strong decomposing effect upon other antiseptics, forms with them, if they have previously been used in the wound, some compound of an especially irritating character. If irritation is seen, a reduction of the strength of the antiseptic is necessary, and still good results will be obtained; for, even in considerable dilution, it is far more effective than pure carbolic acid. The method of the application of the solution varies with the position and extent of the wound. If possible, the wound should be lightly packed with gauze wrung out of the fluid. Underneath the limb a photographer's "developing dish" should be placed, and at intervals of an hour or two a little of the solution should be poured on to the gauze lying in the wound from a Florence flask. The gauze which packs the wound should always be kept damp. It must never be forgotten that there is no such thing as a "gauze drain." Gauze does not drain any wound for more than a very short time; its meshes soon become clogged with lymph, and it is then a plug and not a drain. If the position and extent of the wound do not allow of this method, strips of bandage or of lint may be kept lying out of the wound and their free ends immersed in a dish of the solution, which is then slowly sucked into the wound, whose surfaces it keeps constantly moistened. Or small tubes, with many perforations, wrapped round with one layer of Turkish towelling, may be pushed into the recesses of the wound and left to pass out through a loose dressing of gauze and wool. At frequent intervals small quantities of the hypochlorite solution are injected slowly into the tubes and are diffused through the wounds. This is Carrel's method, and in many cases is the best of all. The skin around the wound may be protected by vaseline. The fluid must always be fresh—not more than five days old. As the solution is so cheap it is not a matter of importance if some quantity of it has to be thrown away. It is very important to ensure that no impermeable material lies outside the gauze, jaconet, or oiled paper, or rubber sheeting. Free escape must always be provided for the Dakin's solution, and for the wound discharges.

I have had the opportunity of trying another preparation of Dr. Dakin's, "chloramine," which in some respects is better than the hypochlorite solution. Chloramine is toluene-sodium-sulphochloramide. The molecular concentration required to kill staphylococci in presence of serum is one-fifth that of the hypochlorite solution. It is very soluble and very easily diffused. After many trials, Dr. Dakin succeeded in preparing chloramine gauze—a gauze in whose meshes powdered chloramine is held. This gauze, thoroughly impregnated with this strongly antiseptic powder, was made in the hope that when introduced into the wound the discharges would dissolve the powder little by little and carry it to all parts of the surface with which they come in contact. In our work in Leeds and elsewhere in the Northern Command we have used a certain amount of this new gauze, with results that justify us in believing that it is the best method so far introduced for checking and controlling the development of infective processes. I have used it in wounds very heavily infected, and its power of cleaning a wound, abolishing the offensiveness of discharges, and bringing about a growth of new healthy granulation tissue is very remarkable. The opportunities for testing its inhibitory properties are very few in civil practice, but such little experience as I possess suggest that it may prove to be one of the most powerful of all known methods for aborting a grave infection in any of the wounds of war.

The researches of Alexis Carrel appear to show that in wounds quite recently inflicted by bullet or by shell the infection at first is slight. When smear preparations are taken at once from the wound surfaces several fields may have to be searched before any micro-organisms are found. Such organisms as are present, even if of no great virulence, finding everything to their liking, grow apace. Every hour that elapses increases the extent, the penetration, and the virulence of the infection. I think, therefore, that the first attack made by a surgeon on a wound

received in battle should be by an antiseptic, and the most powerful which it is proper to use. I do not think that Wright's method is applicable, in the worst cases at least. For, as I have said, the condition of the soldiers who have received severe wounds is one of exhaustion, with lowered blood pressure, cold extremities, feeble pulse, and marked pallor. A few of these patients need infusion before any remedial measures can be attempted, and very many suffer from shock in greater or less degree. The introduction of saline tabloids into the wounds would probably not cause any outflow of serum, and if it did it would be a most undesirable result, for fluid cannot then be spared.

2. THE REDUCTION OR THE ABOLITION OF INFECTION AFTER THIS HAS ONCE BEEN FULLY ESTABLISHED.

When once the processes of suppuration are ablaze in a wound the problem of their treatment, as was recognized by Lister, is a far more difficult matter. To prevent putrefaction in a wound quite recently inflicted, or in a wound about to be made, is by comparison very simple. It is dependence on the certainty of this that has led to all the surgical developments of recent years. To control or check these processes when once they have become rampant is always difficult, and may indeed be impossible. Nothing could be more futile than the methods commonly practised in civil life. A freely suppurating wound may be irrigated for long periods with carbolic or mercuric lotions, and an antiseptic dressing applied; yet when the dressing is removed pus will still be found to pour freely from all parts of the wound, and to lie stagnant on the surfaces of the gauze and wool. In such wounds the old form of dressing is really a pus poultice. We did not realize its hopeless futility before the war, because serious infections in wounds in civil practice are nowadays very rare. A very brief experience of the bountifully purulent wounds of this campaign soon taught us that other methods than these must be found. The methods I have myself practised and seen practised in such cases are briefly the following:

The use of hypertonic salt solution—of a solution consisting of 5 per cent. salt and $\frac{1}{2}$ per cent. sodium citrate. This is the method introduced many years ago by Sir Almroth Wright and revived by him during the present war. Probably every one interested in the surgical treatment of wounds has read all that Sir Almroth Wright has written; if he has not, he should do so forthwith. For his papers state the problems with perfect accuracy and with much insight. The principle of the hypertonic method is to make use of the bactericidal power of fresh serum, which is encouraged to flow from the wound surfaces by the application of a more concentrated saline solution than blood serum. A process of osmosis is at work. It is argued, or rather asserted, which is not the same thing, that serum is a fluid which will not osmose, but the fact is indisputable that when these strongly saline dressings are applied the discharge from all the wound surfaces is increased enormously in quantity. The patient is often compelled to drink freely, so considerable may the drain of fluid be. The discharge from the wound after the first few hours becomes clear, and within two or three days may be found sterile or of low bacterial content. The streptococcus seems the most resistant of all micro-organisms; after two or three days it is often the only germ remaining. As I go round from one hospital to another, or from one ward to another, I think I am generally able to pick out the cases which are being dressed by Wright's solution. The granulation tissues have a fuller, deeper colour, and the surface looks cleaner than when any other form of dressing is being used.

The best method of applying the dressing is that already mentioned as applicable for Dakin's solution. A loose packing of gauze, in a wound well drained, is kept constantly moistened with the salt solution. The copious discharges are collected in a dish. It is important to allow no wrapping up of the limb in wool or swathing in bandages, which restrict the free outward flow of the wound discharges.

There are, however, certain disadvantages in the long continuance of applications of hypertonic saline solution. After the wound has once become thoroughly clean, when the granulations are glowing vividly with health and the discharge is sterile, further treatment with Wright's

solution is apt to cause hæmorrhage, and the granulations become sodden and oedematous. It is therefore desirable before these changes take place to discontinue the treatment. One of two courses may then be followed—either the wound, when of suitable size and proportion, may be closed completely by suture, or its sides may be drawn together by strapping, or some bland dressing may be tried; a dressing of normal saline solution, or of red lotion if moisture is needed; or, otherwise, one with zinc or boracic ointment or sterile vaseline.

As a rule, the treatment by hypertonic salt is painless, but now and again one hears complaints of stinging and burning. To overcome this I had some tabloids made containing chloretone as well as the two salts. Chloretone is a local analgesic of slight power. I think there is some advantage in its use.

A variant of Wright's method, practised by Colonel Lawson and many others, consists in the application to deep anfractuous wounds of a gauze wick into the centre of which tabloids of salt and sodium citrate are placed. There are wounds so placed and of such depth that it is impossible to dress them by the methods applicable in surface wounds. Into the remote recesses of these one or more saline tabloids may be placed, either wrapped in gauze or placed in the extremity of the lumen of a rubber tube, round which a catgut ligature is tied so tightly as to prevent the tabloids from escaping. The tabloids excite a profuse discharge of serum, and the gauze or tube need not be changed oftener than once in every twenty-four hours.

A. E. Morison and Tulloch have advocated the use of a solution of magnesium sulphate in place of sodium chloride. In a preliminary communication² they point out the greater efficacy of their solution in ridding the wound of the streptococcus, which is the hardest and tardiest inhabitant of all war wounds, and the equal efficacy of the solution in cleaning the wound, changing the quality of the discharge, destroying its offensive character, and causing that crimson glow of health which we like to see. In a very few days that blue edge appears on the wound which Solomon had doubtless in mind when he said "the blueness of a wound cleanseth away evil." I have seen some of the wounds treated by Mr. Morison, and can testify that, clinically, his claim is just.

I have had a large experience with Dakin's solution in the treatment of heavily infected wounds, in which the discharge was copious, and very offensive. Its virtues are remarkable. On the first day of trial it was used on three very septic cases in the Isolation Block at the Leeds Infirmary, under the care of Captain A. Richardson. The first case was one of severe infection of the arm arising in an enlarged olecranon bursa. The tissues were sloughing, greenish-black, bitterly offensive. The organisms were cocci, a diphtheroid bacillus, and a coliform bacillus. On the third day the sloughs had all cleared away, the wound was healthy, and no growth could be obtained from the discharge. In two other cases there was a pure culture of the *Staphylococcus aureus*. On the fifth day no organisms were found in the discharge in one case, on the fourth day a very attenuated growth in the other. This experience has been confirmed by many later cases. The most remarkable effect of the application of Dakin's solution is seen in the disappearance of all sloughing, dead and decomposed material. The wound casts them off with great rapidity, and a clean and glowing healthy surface remains. The discharge soon becomes clean, rather "sticky" and inoffensive, and the infection, however virulent, is brought under control or rapidly disappears. It is most essential to dress the wound as I have described. The old methods will not do. A mass of gauze, with tubes securing drainage must be in or on the wound and must be kept constantly saturated with fresh solution. The solution must be newly made every five days; it must not be heated before use, but applied cold or tepid; no other antiseptic may be used at the same time, and the skin must be protected from the occasionally irritant action of this powerful antiseptic. I have found it a little difficult to convince those responsible for the actual dressing of wounds that the old method of applying a layer or two of gauze, a pad of wool, and a firm bandage are utterly unsuitable for the septic wounds of war. Free

access of the antiseptic, constantly renewed, and free escape of the discharges are essential to clean and quick healing.

One of the old fashioned and one of the most successful methods of cleansing the dirty sloughing wound is by constant immersion and irrigation in a bath. For wounds of the hand and forearm, of the foot and leg, this procedure is very simple; but in wounds of the thigh, body, or chest it is difficult or impossible. It is not a matter of any importance as to the antiseptic used in the water; salt solution, a weak solution of carbolic acid, potassium permanganate, or tincture of iodine, all give the same results.

In the treatment of all gunshot wounds where the septic processes are raging, and the temperature varies through several degrees, an immense advantage will accrue from placing the patient out of doors. While in France I developed a great affection for the tented hospitals. There is great movement of air, warmth, and comfort; when a sunny day comes the side of the tent may be lifted and the patient enjoys the advantage of open-air treatment. Major Abye-Curran was the first to convince me of the striking effects caused by exposing uncovered septic wounds to the air and the sun. Wounds which were sullen in healing quickly brightened and became clean. Even in the winter and in Leeds and Sheffield we have some patients out of doors day and night. On Monday last I saw at the 3rd Northern General Hospital with Lieutenant-Colonel Connal a row of beds in the open occupied by ruddy, happy men with quickly healing wounds. I asked many of the patients how they liked the exposure, and all at once replied that they were quite happy and "wouldn't go inside to sleep if they could help it." I am confident we do not sufficiently take advantage of the immense help which open-air treatment can give to patients suffering from the serious wounds of war. I find that wounds clean more rapidly, patients sleep better, eat better, and feel better when they are kept out of doors night and day. The vagaries of the temperature chart need not influence our decision as to the wisdom of this treatment. Many years ago I learnt at Johns Hopkins Hospital that a high septic temperature was an indication for moving the patient on to a balcony rather than a reason for dreading the effects of exposure.

I cannot properly omit mention of the vaccine treatment of patients suffering from septic wounds. It is remarkable to find such widely divergent opinions among physicians and surgeons as to the virtue of a vaccine in any disease. When opinions are so wide apart, so confidently expressed, and so utterly irreconcilable, it is probable that opportunities for judgement are not identical. The changes in wounds are often so swift when any one of the recognized modes of treatment is tried, or indeed when little of value is done; a vaccine when tried is so often only one of several agents brought to bear almost at the same moment upon the patient and his wound; degrees of change in a wound are so difficult to express in terms of accuracy, and their appreciation depends so much upon the desires and prejudices of the observer, that argument and experience are alike fallacious. But no one can deny, I think, that a case has been made out for the trial of vaccines in appropriate cases, and in suitable conditions. The principle of the vaccine method is, of course, to fortify the blood serum in respect of those bodies which are inimical to the development or to the life of an invading micro-organism. If, therefore, a wound is imperfectly drained or not properly dressed, the administration of heroic doses of the most potent vaccine is merely futile. When, however, a wound is well drained and there is a free access of serum to the wound, with a free opportunity for its discharge into the wound and of rapid escape from it, then it would seem reasonable to suppose that the more potent the bactericidal power possessed by the serum, the greater will its effect be in causing the wound to clean and to heal. This suggests that the vaccine treatment, in conjunction with the application of Wright's solution, will be likely to give the best results. Of the great value of the streptococcus vaccine in the serious wounds of this war I am thoroughly convinced, and I have no doubt whatever that advantage would be gained by a freer use of it in cases of infection with this most obdurate organism. So much has reference to the therapeutic use of these agents.

Their prophylactic virtues, if they possess any, have not yet been given a full trial in this war. It would be interesting to watch the effects of vaccines given before a man goes into action, or to a man immediately after his wound is inflicted. But the factors at work are so many, so variable from time to time, from place to place, and from man to man, that the scrutiny of inoculated cases would require powers of analysis denied to most of us. Sir Watson Cheyne, the redoubtable champion of the antiseptic methods—and, indeed, one of the earliest and most successful pioneers of modern surgery—has suggested that bacteriologists have a very great opportunity at the present time, and that they may profitably be employed in raising the immunity of new recruits against all the ordinary bacteria which occur in wounds received in war time.

One of the most sensational experiences in connexion with all wounds, even the most trivial, is the inordinate length of time that micro-organisms may remain dormant in the tissues long after healing is complete. I have seen tetanus and gas gangrene develop in wounds many weeks after their infliction when relatively trivial operations were performed upon them for the purpose of extracting bullets, shell-casing, or fragments of khaki cloth. Even the passive movement of a stiff joint, in whose neighbourhood there is a healed wound, may light up a raging septic process which threatens or takes the patient's life. It appears to be more especially in cases where compound fractures of bones have occurred at the primary injury that these grave troubles are apt to arise. A knowledge of the danger must warn us always to be on guard against premature surgical interference in wounds recently healed, or in sinuses which fail to close.

REMARKS ON DELAYED TETANUS.

THREE CASES, IN ONE OF WHICH GAS GANGRENE DEVELOPED SEVENTY-THREE DAYS AFTER A WOUND.

By GILBERT BARLING, M.B., F.R.C.S.,

LIEUTENANT-COLONEL R.A.M.C.(T); CONSULTING SURGEON TO THE SOUTHERN COMMAND.

At the 2nd Birmingham War Hospital we have had the unusual experience of three cases of tetanus occurring respectively fifty-one, fifty-three, and forty days after suffering wounds, the three cases being under treatment simultaneously.

CASE I.—*Tetanus with an Incubation of Fifty-one Days.*

Private M., aged 20, wounded August 20th, 1915, by shrapnel in the left shoulder and lower lumbar region of spine. The injured parts were treated immediately by iodine, and two hours later the patient was given a prophylactic dose of anti-tetanus serum subcutaneously. A few days later bits of shell were removed from the lumbar wound.

When he was admitted to the 2nd Birmingham War Hospital, on September 20th, the shoulder wound was found to be healed; the lumbar wound was suppurating, and a radiograph showed fracture of the body and transverse process of the fifth lumbar vertebra, but no foreign body. There was threatening of suppuration in the right axilla, and four days later a considerable amount of pus was evacuated from this region.

On October 10th he experienced difficulty in opening his mouth; some days later rigidity was noticed in the muscles of the back and in the sterno-mastoids.

I first saw the patient on October 30th; he was then sweating rather profusely, risus sardonius was well marked, the masseters and sterno-mastoids were only slightly rigid, the belly muscles were very rigid; there was no distinct opisthotonos, though the muscles of the back were rigid. Antitetanic serum was at once given subcutaneously and continued until November 11th, when the tetanic symptoms had practically disappeared; altogether 37,500 units of the serum were given.

The symptoms in this case were much less severe than in the two about to be recorded.

CASE II.—*Tetanus with an Incubation of Fifty-three Days.*

Lance-Corporal M., aged 22, was wounded on September 25th, 1915, by a bullet which passed through the left forearm, fracturing the radius and ulna, and by another bullet in the upper part of the right arm. A dose of antitetanus serum was given subcutaneously two days later.

On admission to the 2nd Birmingham War Hospital on October 1st, 1915, the forearm wound was healing well; the

wound in the upper arm was suppurating. On November 13th a tiny fragment of cloth was removed with a probe, and later a piece of the casing of the bullet was removed with a fragment of cloth wrapped up in it, as shown in the drawing. Cultiva-

The casing of the bullet is shown with a piece of cloth through it like a wick. The case entered base first.

tation taken from this under anaërobic conditions failed to grow the tetanus bacillus.

On November 17th there was marked stiffness of the neck and back and inability to open the mouth freely. The sterno-mastoids and the muscles of the abdomen were rigid; he was sweating profusely. The temperature was 98° F.; 3,000 units of antitetanus serum were injected subcutaneously and repeated at first every six hours.

During the next few days the symptoms were very severe, difficulty in swallowing was pronounced, spasms were severe, sweating was profuse. An erythematous rash appeared twenty-four hours after the first injection; this was a source of much inconvenience to the patient, and he also experienced a good deal of discomfort in his joints on the tenth and following days. By November 25th a distinct improvement in the tetanus symptoms had occurred, and after this there was no real anxiety as to the patient's condition.

On December 4th, when the doses of serum had been reduced to two in twenty-four hours, a fresh lot of serum caused a recurrence of the rash. On December 8th all symptoms had disappeared. The records show that the temperature at its highest was 102° F., the quickest pulse-rate was 138, and the total quantity of serum given was 153,000 units.

CASE III.—Tetanus with an Incubation of Forty Days, followed by Gas Gangrene Seventy-three Days after Injury and Forty-two Days after the Wound had Healed.

Private S. was wounded in the right upper arm on September 25th, 1915, a flesh wound only. He was admitted to the 2nd Birmingham War Hospital on October 1st and transferred to a convalescent home on October 27th. The case paper states that the wound was then healed. There was no evidence that a prophylactic dose of antitetanus serum had been given.

On November 3rd he complained of pain in the shoulder and back, but was up and about. The next day he was confined to bed, as he complained of difficulty in swallowing and of stiffness of the lower jaw.

On November 8th he was sent back to the hospital. The note then made states that the reflexes generally were increased and ankle clonus was elicited; the muscles of the jaw, neck, back, and abdomen were very rigid; the tongue was occasionally bitten, the right arm was rigid, clonic spasms and slight opisthotonos occurred occasionally, sweating was profuse. Antitetanus serum (3,000 units) was given subcutaneously and repeated every six hours. Bromide and chloral were given by the mouth.

On November 10th the pulse was very rapid and weak; respirations 40. He had had no sleep until morphine gr. ½ was given subcutaneously; this was followed by three hours' sleep. During the following days the records gave alternating accounts of slight improvement and relapses, but the patient was extremely ill and frequently delirious; the pulse varied from 100 to 160, the temperature from 100° to 104.5° F.

On November 18th the tetanus symptoms were much less marked and the amount of serum given was diminished and finally stopped on November 29th, when the patient had recovered from tetanus. He received altogether 189,500 units.

On November 30th there was dullness and crepitation at the base of the right lung, and on the same day a small abscess was discovered in the right thigh, from which a streptococcus was cultivated.

During the next days the patient improved somewhat, as did the physical signs in the lung, but on December 5th the temperature rose to nearly 104°, the pulse was 120, the tongue was brown and dry, and the patient was generally delirious. On December 6th the conditions remained practically the same, but it was noted that the base of the right lung was almost clear and that the scar of the wound was unaltered. On December 7th the note was, "Much the same, scar unchanged." On December 8th he was very delirious, at times unconscious, the scar was distended and livid, with brown discoloration around, the shoulder region was tympanitic. Free incisions let out stinking gas, but very little discharge; the tissues were quite insensative when incised. The patient died early on December 9th.

For the clinical notes I have to thank Major Housman, R.A.M.C., Dr. Archer, and Dr. Foster,

Pathological Report.

The following pathological report is by Dr. C. J. Lewis, visiting pathologist to the hospital, to whom I am greatly indebted for the trouble he has taken in investigating the bacteriology of the case.

At the autopsy subcutaneous emphysema was found over the whole of the chest and neck, the lungs were densely black and

emphysematous, the spleen was enlarged, black, and semi-gangrenous at the upper part.

On December 6th, 1915, a specimen of pus from the (right) thigh yielded *Streptococcus pyogenes* in pure culture.

At the post-mortem examination cultures were made from the spleen and from the gangrenous area near the right shoulder. The former yielded the streptococcus and the latter an anaërobic bacillus in addition to the streptococcus. This bacillus belonged to the type of organism described sometimes as *B. perfringens* and sometimes as *B. abrogenes capsulatus*. It was identified by its morphology and staining reactions, by the characters of its colonies, by the odour of its cultures, and by the rapid production of much gas.

Deferred or latent infections are always of great interest. They occur in infections of the most diverse kind, but are more common perhaps, or at all events more frequently recognized, in tubercle and are less common in connexion with organisms which develop quickly. In carcinoma we occasionally see something parallel to the development of latent infection. Many years, ten or more, after the excision of a carcinomatous breast and when the absolute cure of the patient seemed assured carcinoma may develop in the supraclavicular lymphatic glands. The explanation can only be that for a very long period cancerous emboli have existed in one or more of the glands, have been kept in check but not killed by the resistance of the surrounding tissue or by something circulating in the blood. Then, owing to some alteration in the patient's resistance, the embolus starts growing vigorously, and a fatal process of disease is established. What the circumstances are, what the particular factor is which activates the disease, whether in recognized bacillary infections or in malignant emboli, we are often unable to recognize, but sometimes we are provided with a striking illustration which almost resembles an experiment in a laboratory. The following is an example. A young girl suffered from typhoid fever, and experienced an osteitis of the lower end of one radius. This subsided and the patient worked regularly in a factory for five years, then went for a day in the country on a bank holiday, dressed without regard to the weather, and was, early in the day, soaked to the skin, and so remained until the end of the day. She was indisposed as the result of the chill thus sustained, and a few days later the forearm became painful and swollen. On admission to the General Hospital, five weeks after the incident above related, the lower part of the girl's forearm was found to be swollen and tender, the skin over the radius was red, and fluctuation could be detected. Pus was evacuated, a sequestrum the size of a horse-bean removed from the radius, and cultivation gave a pure culture of the *Bacillus typhosus*. The organism in this case appears to have been activated, after five years of quiescence, by changes in the general body tissues induced by chill, rather than by changes in the locality, for there was no evidence of local injury. It is a commoner experience to find that local damage activates the infection; this is especially true of injuries in the neighbourhood of joints, and may be true in some cases of tetanus in which operation, in the presence of the tetanus bacillus, hitherto not recognized by its clinical effects, has been followed by the development of the disease.¹

To return to the cases I have related. It is certain that two of the patients received each a prophylactic dose of antitetanus serum; in the third case it is uncertain whether a similar precaution was taken. A point of great interest arises: May a prophylactic dose delay the onset of tetanus by directly influencing the growth of the infective organism and so reduce its virulence that it only shows its clinical effect under some special condition favouring more vigorous growth? Or alternatively, does the antitoxin given prophylactically neutralize the first formed toxin and so prevent the development of clinical symptoms, despite the growth of the infection, until all the antitoxin has been saturated? Some light may be thrown on these questions by scrutiny of the cases of delayed tetanus furnished to the War Office, especially if the statistical report is supplemented by experimental observation on animals.

The occurrence of gas gangrene seventy-three days after the infliction of a wound and forty-two days after the wound had healed, appears to be unique as far as I can learn by inquiry and such search as I have been able to make in current literature.

My impression is that the *Bacillus perfringens* was activated by the association with it of a streptococcus in

a subject exhausted by a severe attack of tetanus which, though recovered from, had made a deep impression on the patient.

THE TREATMENT OF TETANUS,

WITH SPECIAL REFERENCE TO THE USE OF ANTITETANIC SERUM AND THE LOCAL TREATMENT OF THE WOUND.

BY

R. G. ABERCROMBIE, M.D. CANTAB.,
TEMPORARY CAPTAIN, R.A.M.C.

As a result of his recent statistical analysis of 231 cases of tetanus Sir David Bruce¹ comes to the conclusion that the therapeutic value of the antitetanic serum is doubtful, although he still recommends its use.

The study of individual cases, however, may sometimes serve to supplement the statistical method, and a series of four cases of tetanus recently under my care are of interest, for in them the serum appeared to be of unmistakable value. In two the symptoms subsided under treatment by large doses of serum; on the reduction of the dose the symptoms reappeared with great violence, and on the renewal of large doses the symptoms once again subsided.

The four men were all wounded last autumn. None of them had received a prophylactic dose of serum.

CASE I.

Granulating shell wound of buttock; fragment of shell palpable beneath skin over sacrum. Incubation period, ten days. The symptoms were trismus, rigidity of neck and abdomen, painful spasms of legs. Respiration not affected; able to swallow fluids.

The patient stated that slight stiffness of the jaws had been present on the day preceding the beginning of serum treatment, which therefore commenced on the second day of the disease. From the second to sixth day 9,000 units were given daily; on the second, fourth, and sixth days 3,000 units of this dose were given intrathecally, the remainder being divided equally between the intravenous and subcutaneous routes.

Seventh day: Improved; able to open mouth; 5,000 units given subcutaneously. Eighth and ninth days: Improvement continued; serum omitted. Tenth day: Improvement maintained; 4,500 units given subcutaneously, with the aim of preventing relapse. This was insufficient for its purpose, for on the eleventh day a severe relapse occurred, with agonizing spasms of the legs; 3,000 units given intrathecally, 7,000 units intravenously. Twelfth day: Symptoms subsided; 7,500 units given subcutaneously. Recovery.

Duration of symptoms, twelve days; this period is reckoned up to the last day upon which slight tetanic spasms were present, although in this and the succeeding cases slight stiffness of the affected muscles persisted for several days longer.

CASE II.

Bullet wound of thorax; fractured ribs; small effusion into left pleura, regarded as sterile hæmothorax. Incubation period, twelve days. Trismus; severe respiratory spasms with deep cyanosis; deglutition impossible.

For the first five days 9,000 to 12,000 units were given each day, part subcutaneously and part intravenously; for the first three days 3,000 units of this dose were given intrathecally. Sixth day: Marked improvement; spasms few and slight; deglutition easy; 7,500 units given subcutaneously. Seventh day: Improvement continued; serum omitted. Eighth day: 5,000 units given subcutaneously to prevent relapse. Ninth day: Severe relapse; 10,000 units given intravenously, 6,000 subcutaneously. Tenth day: Considerable improvement; spasms less frequent; 7,500 units given intravenously and repeated in afternoon. Eleventh day: Large hæmorrhage from rectum, and death.

Duration of symptoms, eleven days.

Post-mortem Examination.—A superficial erosion in rectum; lower gut packed with scybala, although an enema had been given on alternate days. Small septic effusion in left pleura.

CASE III.

Shell wound of thigh. Two days after the injury the wound had been freely incised for gaseous cellulitis. At the time of the onset of tetanus large sloughs of muscle were in process of separation by granulation.

Symptoms of tetanus occurred ten days after the date of original wound. Trismus and backward curvature of spine; deglutition and respiration unaffected. The patient stated that slight stiffness of jaws had been present on the day preceding the initiation of serum treatment, which thus commenced on the second day of disease.

Second day: 3,000 units intrathecally, 3,000 intravenously, 3,000 subcutaneously. Third and fourth days: 6,000 units intravenously, 3,000 units subcutaneously. Fifth day: No

definite spasms, but occasional twitchings; 4,000 units intravenously, 2,000 units subcutaneously. This dose repeated on sixth day. Transferred to England, having been free from tetanic symptoms for twenty days. Duration of symptoms, six days.

The muscular sloughs were allowed to separate by granulation.

CASE IV.

Granulating shell wound of thigh. Incubation period, nine days. Trismus, rigidity of neck, painful spasms of wounded leg, tongue frequently bitten. Respiration and deglutition unaffected.

First day: 3,000 units given intrathecally, 4,000 units intravenously, 2,000 units subcutaneously. Second to eighth days: From 7,500 to 10,000 units given daily, chiefly intravenously; on the fourth day 3,000 units of this dose were given intrathecally. Ninth day: Spasms absent; serum omitted. Tenth day: Slight spasms present; 4,000 units intravenously, 1,000 subcutaneously. Eleventh to thirteenth days: Spasms absent, serum omitted. Fourteenth day: Very slight spasms; 4,500 units subcutaneously. Transferred to England, having been free from spasms sixteen days. Duration of symptoms, fourteen days.

In Cases I and II formidable symptoms subsided under large doses of serum, reappeared when the doses were diminished, and again subsided when the large doses were repeated; in each case the relapse occurred on the day following the injection of about 5,000 units subcutaneously. Hence it appears probable that small doses may fail where large ones succeed. Although Case II ultimately died from complications, the effect of the serum in influencing grave tetanic symptoms was marked. The cause of the rectal hæmorrhage is not clear; it would be of interest to learn whether purpuric symptoms have followed large doses of serum in other cases.

The value of intrathecal injection was shown in the relapse of Case I; after the injection, the agonizing spasms of the legs completely subsided, and did not recur. Possibly the intrathecal route is specially valuable when the wound is in the lower part of the body and the spasms localized to the lower limbs, for by this route the serum is brought into immediate relation with the affected lower part of the cord.

Daily Dose.

The effectual daily dose would appear to be about 10,000 or 12,000 units; this may be given twice a day in critical cases. The major portion of this dose should be given intravenously; subcutaneous injections being also used to maintain the effect. Intrathecal injections should be given daily, or at such intervals as the symptoms demand. The dosage must be reduced gradually, in order to avert relapse.

It is worth noting that three of the above cases exhibited a characteristic narrowing of the palpebral fissure, a symptom which I have also observed in several other cases of the disease. This is probably due to a slight continuous contraction of the orbicularis, although the drooping upper lids may sometimes resemble bilateral parietic ptosis. It is more persistent than the risus sardonicus and occurs earlier in the disease, and may therefore be of diagnostic value.

Local Treatment of the Wound.

All will agree as to the desirability of the vigorous treatment of soiled wounds as a preventive of tetanus; but when once the disease has declared itself, I consider that operative surgical interference with the surface of the wound, although recommended by several authorities, is a proceeding of considerable danger. This view is based on theoretical considerations, and on the study of eleven cases during the war.

Tetanus usually shows itself after an interval of a week or more from the time of the injury. By this time there will have been formed the protective inflammatory barrier, the function of which is to check absorption from the surface of the wound. Any active surgical treatment, such as scraping, incisions for drainage, or the removal of sloughs, is likely to make breaches in the inflammatory barrier, and to expose the tissues to the access of the tetanus toxin; and this will hold good whether the toxin gains entrance by way of the nerves, the circulation, or the lymphatics.

The following case illustrates this point:

A patient with septic compound fracture of the leg was well on the road to recovery from a severe attack of tetanus; a

simple incision was made for the evacuation of a collection of pus and the removal of a fragment of dead bone. Although a precautionary dose of serum had been given, the operation was followed within eight hours by a violent relapse of the tetanus.

It is probable that the relapse was not due to the shock of the operation, but to the exposure of a fresh absorbent surface, for I have not observed any similar recrudescence of tetanic symptoms following the administration of an anaesthetic for such purposes as lumbar puncture or the dressing of a wound.

In another case the patient had been wounded in the back; six days after the wound an operation was performed for the removal of a missile lying upon the lamina of the first lumbar vertebra. For a few hours before the operation the patient had complained of severe pain in the wounded portion of the back; this was not at the time recognized as due to the onset of tetanus, although subsequent events showed that the pain had probably been due to that cause, for it increased after the operation, and in six hours was accompanied by trismus. Death from rapidly developing tetanus took place within sixteen hours of the operation.

MacConkey³ has recently collected several instances of operations upon wounds followed after a short interval by the development of tetanus in patients who had previously shown no signs of the disease. It is probable that these cases illustrate the danger of making breaches in the inflammatory barrier.

That the policy of non-interference with the wound may be followed without detriment to the patient is proved by Case I and Case III above. A fragment of shell in one case and large muscular sloughs in the other were left undisturbed; both patients recovered. In each case the belief was justified that it was safer to trust to the protective power of the inflammatory zone than to risk the exposure of a fresh absorbent surface.

While avoiding injury to the granulation tissue, every effort should be made by gentle means towards the removal of debris and the cleaning of the wound; for this purpose irrigation with hydrogen peroxide, followed by irrigation with the hypochlorite of soda solution, may be employed.

The objections to interfering with the infected surface of the wound do not apply to amputation above the site of injury. In cases of tetanus associated with septic compound fracture the patient is exposed to danger from the sepsis as well as from the tetanus, owing to the impossibility of preventing movements of the fractured bones; I have observed two such cases in which the patient survived the tetanus but ultimately died from septicaemia. In cases of this nature early amputation probably affords the best chance of recovery; this course was followed successfully in a case under my care. Antitetanic serum was injected into the nerve trunks exposed in the stump at the time of operation.

In an account of the German experiences of tetanus, Pribram⁴ recommends radical excision of the wound. Owing, however, to the extensive nature of the injuries usually associated with tetanus during the present war, complete excision of the wound would almost invariably be quite impracticable; any attempt to perform it would be necessarily incomplete, and would probably do more harm than good. The case-mortality of tetanus amongst the Germans appears to have been very high.⁴

CONCLUSION.

When tetanus has declared itself, operative surgical interference with the infected surface of the wound is dangerous, and should be a matter for grave consideration; it is preferable to imitate nature's methods—namely, to promote the formation of granulation tissue, and simultaneously to reinforce the patient's production of antitoxin by the injection of large doses of antitetanic serum.

It is reported from Sweden that the actual delivery of the Nobel prize in chemistry for 1914, awarded to Professor Theodore W. Richards of Harvard University, together with the other Nobel prizes for 1914 and 1915, will be postponed until June 1st next. The prize winners are invited to go to Sweden in person to receive their prizes and to give their Nobel lectures.

VISUAL NEUROSES OF MINERS IN THEIR RELATION TO MILITARY SERVICE.

BY

CHARLES F. HARFORD, M.A., M.D. CANTAB.,
M.R.C.S. ENG.,
TEMPORARY LIEUTENANT R.A.M.C.

THE visual defects of miners have been the subject of careful investigation by members of the profession, and miner's nystagmus in particular has received close attention, and the monograph on this subject by Dr. T. Lister Llewellyn, entitled *Miner's Nystagmus, its Causes and Prevention*, may be thought to have said the last word on this peculiar affection. It may, however, be of interest to record some of the cases which have been met with recently among miners coming from the counties of Northumberland, Durham, and Yorkshire, who have found their way into the army. There may also be some advantage in noting the persistence and, in some cases, the aggravation of these defects in men removed far from the scene of their former work and employed entirely above ground. I had not previously had the opportunity of noting cases of this disease, and therefore approached the subject with some freshness. I have purposely abstained from using the term "miner's nystagmus" for reasons which will be stated, but nevertheless the series of cases given are, in my opinion, examples of the affection which usually bears this name.

It is obvious that the cases quoted are too few to be of themselves of great value, but the fact that they are corroborative of cases quoted by Dr. Llewellyn seems to indicate their similarity to the condition which he describes.

1. In the first place, there can be little doubt that the group of associated symptoms which are present in what is usually known as "miner's nystagmus" constitute a distinct "disease."

2. On the other hand, the name seems to be unfortunate, seeing that the nystagmus is at most only one symptom out of a group which may be absent even when the "disease" is present in a marked form.

3. The symptoms noted in the series of cases given below correspond very closely with those described on pp. 1 and 2 of Dr. Llewellyn's monograph, and it may be convenient to refer to these *seriatim*, taking them in the order of apparent importance.

(a) Defect of Vision.

This is variable in different cases, and probably is due to a variety of causes, but it has usually been the chief reason which has led to the man in question being sent for examination. There is usually some error of refraction present, but this is insufficient to account for the defective vision, and it will be seen that some of the cases were hypermetropic, some myopic, and some astigmatic in different degrees. In no case was any abnormality of the fundus detected to which any of the disturbance of vision could be attributed, but it was not possible to make an ophthalmoscopic examination in the cases where there was marked photophobia.

(b) Temporary Giddiness.

Next to the visual disability, the occurrence of more or less pronounced attacks of giddiness was a reason for the cases coming under observation. In two instances men complained that they found it dangerous to be on horse-back, and one man came into hospital suffering from bruises because he had fallen from his horse and been dragged along by it. Case I, which was much the worst of the series, used to have attacks of giddiness, in which he would often have fallen if he had not been held up by attendants in hospital. Others would simply complain of feeling "dizzy," often in the early morning; in no instance could it be proved that there was any absolute loss of consciousness.

(c) Photophobia.

Intolerance of light was present in some measure in practically every case, and this symptom may be responsible for the blinking of the eyelid in some cases, the drooping of the lids in others, and the difficulty which was generally experienced in looking upwards. Judging from the occurrence of this symptom in other forms of disease

affecting the eye, it seems most likely that it is due in this instance to some irritability of the retina, for it is suggestive of the photophobia met with in albinos, or in cases where the pupils are widely dilated in a bright light. There was never any corneal trouble present, and only in two cases marked conjunctivitis, but this was not sufficient to explain the photophobia.

(d) Headache.

In most cases there was a complaint of very frequent pain, chiefly in the temples, either at night or in the early morning. Most of them associated this with injuries to the head which they had received in the pit. While there may be some ground for this, the occurrence of the headache, together with other symptoms, was suggestive of that form of headache often met with in cases of functional nerve disorders.

(e) Perverted Visual Impressions.

Under this heading may be mentioned the very general complaint of various apparent movements of lights, referred to by some as "dancing lights," "glittering lights," "dazzling lights," and so forth. It seems that these subjective impressions have been directly associated by most observers with the occurrence of the special form of oscillation of the eyeballs which constitutes the nystagmus. It is very doubtful whether this is so. In other forms of nystagmus there does not seem to be any occurrence of similar visual impressions, and the disorder is probably due to other causes. However this may be, the fact remains that the meeting of lights shining out of darkness, whether they are lamps in a pit or gas lamps on a dark road, seems to set up peculiar disturbances of vision which greatly distress the patient and interfere with many occupations. The symptom which has been referred to as "night blindness" is hardly a true "night blindness," but darkness seems to accentuate most of the symptoms, and it is a strange anomaly that "fear of the light" and "fear of the dark" should be present in the same cases, but so it is.

(f) The Mental Factor.

No one can have watched a number of these cases without recognizing the very great importance of the mental factor. In spite of the fact that the cases were not spoken of in the patients' hearing as "miner's nystagmus," and that no diagnosis was put upon their diet sheets, yet all seemed to be introspective and oppressed by their condition. In most cases detention in hospital seemed to have a depressing rather than a helpful influence, and the graver cases tended to grow worse in spite of change of treatment. Bromides, stomachics, tonics were tried in succession, but all without benefit. Probably the different cases reacted unfavourably upon one another, and yet it was difficult to keep them apart.

(g) Nystagmus.

In those cases which have for months been working above ground this symptom was either not present or was at least very difficult to detect. There is no suggestion that the symptom is not as prominent as has been described in recent cases, but it is significant that in the circumstances in which these men were living the symptom seemed to have disappeared. Some may on this ground question the diagnosis, but it is not likely that any one who has read Llewellyn's book will be inclined to do so.

4. The question now arises as to the effect of military service upon this affection. There seems to be no room for doubt that it is a serious mistake for men who have any tendency to the complaint to be subjected to the arduous strain of military service, which not only involves exertion of all the powers of body and mind, but particularly of the eyesight, and it may be worth while to bear this in mind in examining recruits for the army from the mining community.

5. There is, however, another question of even greater importance, and that is the relation of the disease to military efficiency. From the insidious character of the symptoms serious results may follow from the inclusion in the army of men who may become quickly incapacitated. When it is realized that the vision may without obvious cause be seriously impaired, that vision at night time may be reduced to a minimum, and that attacks of giddiness

may come on at any time, it will be believed that the presence of such a man might prove to be a source of serious danger to his unit if any dependence was placed upon him.

6. In conclusion, it will be seen that no attempt has been made to throw light on the causation of the disease, as this has been very fully worked out, and as the cases given were those which were seen apart from the surroundings in which the disability was acquired; but I desire to express very strongly the view that this affection, which is of such vast importance to miners, and which seriously affects the military efficiency of those who suffer from it, needs to be more carefully studied by the neurologist rather than by the ophthalmologist. It is true that the avenue through which the nervous system is deranged is the eye and that vision is disturbed by it, but it seems clear that the "disease" is a general nervous ailment and should be studied as such, and that too great prominence should not be given to the nystagmus, which is only one symptom in the case. If this course were followed it is possible that better results might be obtained by treatment, which, it will be admitted, is very unsatisfactory in the severe cases. Only one comment may be made here under this head, and that is the possible benefit of suggestion, particularly in view of the great importance of the mental factor.

In the following list of cases it is only possible to state the age of those who were in-patients, but the others were all men of military age. The result of ophthalmoscopic examination is not given, but this was carried out where possible without any abnormal appearances being detected.

CASE I.

A driver, R.F.A., aged 33, was admitted to hospital on June 11th, 1915, on account of defective sight and staggering gait. The following symptoms have been specially noted during two months in hospital, and have gradually increased in severity. V. = R. $\frac{2}{2}$; L. bare perception of light. He can only get about with great difficulty, chiefly by feeling his way. The staggering is probably mainly due to inability to see clearly, but there is also some stiffness of limbs, and there is a kind of spasm on tapping over the patellar tendon. There is marked photophobia, which makes it exceedingly difficult to examine him. Much blinking of eyelids, irregular movements of eyeballs, and apparent inability to fix upon any point, but no definite nystagmus. He says that the symptoms are worse at night, and that then, especially, things seem to dance before his eyes. He complains of almost constant pains in the temples and the occipital region. He sleeps badly, is much depressed, and has nervous attacks, especially at night, in which he does not seem to lose consciousness, but is much agitated.

Previous History.—He stated that he had worked in a pit since the age of 11, and was always short-sighted. He ascribed his trouble to various accidents: Eight years ago, when he was buried in a mine accident; seven years ago, when he was kicked by a horse, and had an injury to the skull as well as breaking his jaw. The symptoms have been worse for the past three years.

Family History.—His father is said to have been "short-sighted." He has four brothers, three of whom are said to be "short-sighted" and two affected similarly to patient. They all work in mines.

CASE II.

A private in an infantry regiment, aged 34, was admitted to hospital on July 1st, 1915. He had previously been seen as an out-patient, when his vision was $\frac{2}{2}$ in each eye. It is not easy to say how far the defective vision was due to any real inability to see, or whether it was occasioned by the well-marked photophobia which made it difficult for the patient to look at any object for a sufficiently long time. There was some fine oscillation of the eyeballs in a lateral direction when the lids were held open, but no rotatory movement was detected. The drooping of the lids, as in Case I, corresponded with the illustrations given by Dr. Llewellyn as characteristic of this disease. He has some conjunctival congestion, but no staggering gait or severe headaches.

Previous History.—He stated that he started work in the pits at the age of 12, and that at the age of 15 he had a bad fall, hurting his head, and has never been well since. He ascribed his recent failure of sight to an attack of discharge from the eyes, from which he said that his wife and four children had suffered.

Family History.—Father and mother are said to have weak eyes, as also four brothers who are working in the pits.

CASE III.

A gunner in the R.F.A., aged 28, was admitted to hospital on July 9th, as he had fallen from his horse, so he stated, on account of an attack of giddiness. He had twitching of the lids and slight photophobia, but no nystagmus. The symptoms were worse in the evenings, when he suffered from severe pains in the temples. He stated that whenever he got upon a horse objects seemed to be dancing about in front of his eyes. V. = R. $\frac{2}{2}$; L. $\frac{2}{2}$; not improved by glasses.

Previous History.—He had suffered for six years from somewhat similar symptoms.

CASE IV.

A driver in the A.S.C., seen as an out-patient on July 9th, 1915, complained of defective vision, which, however, was due to myopia, as follows: V. = R. $\frac{1}{2}$ c - 3 D. = $\frac{1}{2}$ partly. L. $\frac{1}{2}$ partly c - 2.25 D. = $\frac{1}{2}$ partly. With both eyes $\frac{1}{2}$. At the same time he complained of difficulty as a driver, as he felt unsteady and wished to be transferred to an infantry regiment. There was no sign of nystagmus at time of examination.

Previous History.—He stated that he had always had bad sight, that a few years ago he had suffered from nystagmus, that he was affected by the lights in the pit, and that he found difficulty in staring at lights at the present time. He said that he had been at various times in the army, but had twice been discharged on account of bad sight (probably myopia).

Family History.—Father's sight good; mother's sight weak; eight sisters and one brother have good sight; one brother is said to have suffered in the same way as the patient.

CASE V.

A private in an infantry regiment attended as an out-patient for test of vision on July 14th, 1915. V = R. $\frac{1}{2}$ c, and L. amblyopic; hypermetropic with some astigmatism; not improved by glasses to any appreciable extent. He complained of pain in the head, and said that he could not bear a strong light.

Previous History.—He stated that he had had weak eyes all his life, that he had had an accident to the head as a child, to which he ascribes the failure of the left eye; that two years ago he had inflammation in both eyes, and that since then he has noticed dancing or flickering lights when working in the mine. He was better after joining the army until he started musketry practice.

CASE VI.

A private in an infantry regiment came up on July 15th, 1915, as an out-patient for examination of eyes.

V. = R. $\frac{2}{3}$ c + 2.5 D. cyl. ax. $\setminus 50^\circ = \frac{1}{2}$ pty.
L. $\frac{1}{2}$ c + 2 D. cyl. ax. | vert. = $\frac{1}{2}$ pty.

Previous History.—He had been troubled with his eyes for twelve months, especially in looking at lights in the pit, and at night when above ground.

CASE VII.

A private in an infantry regiment was seen on July 17th, 1915, on account of failure at musketry practice.

V = R. $\frac{1}{2}$ pty. c - 3 D. cyl. ax. — hor. = $\frac{1}{2}$ c.
L. $\frac{1}{2}$ pty. c + 2 D. cyl. ax. | vert. = $\frac{1}{2}$ c.

There was some slight sign of oscillation of eyeballs, and it was difficult to get him to look upwards.

Previous History.—He stated that he had suffered from miner's nystagmus, which he believed was caused by knocks over the eyes. He complained of the glittering of lights in the dark and of the moving of things before his eyes, especially if reading a paper.

CASE VIII.

A private in an infantry regiment, aged 33, was admitted July 9th, 1915, on account of conjunctivitis.

V. was at first $\frac{1}{2}$ c in both, improved in hospital so that on August 18th it was

V. = R. $\frac{1}{2}$ c - 1 D. = $\frac{1}{2}$. L. $\frac{1}{2}$ c - 1 D. = $\frac{1}{2}$.

There was much blinking of eyes and complaint of pains in the temples, and occasional giddiness, causing a fall one evening.

Previous History.—He stated that he had had many knocks on the head, some of which had stunned him. He seems to have had conjunctivitis at the age of 21. For a long time he had been dazzled by lights in the pit, and when he passed a lamp in the street at night time he had to shade his eyes; he said that he often turns dizzy.

CASE IX.

A private in an infantry regiment, seen on July 26th, 1915, said that he had had nystagmus five years previously, when he was off work for six weeks.

V. = R. and L. $\frac{1}{2}$ c, improved by + glasses with a weak cylinder to $\frac{1}{2}$ c.

CASE X.

A private in an infantry regiment, seen on August 5th, 1915, stated that he had suffered from miner's nystagmus two years previously, and was obliged to leave the pits. V. = R. $\frac{1}{2}$ c, not improved by glasses; L., amblyopic. Refraction hypermetropic.

THE fortieth annual report of the Boston Medical Library, presented on January 11th, shows that the war has caused a great falling off in the number of books and journals received. During 1915 seventy-six foreign periodicals had suspended publication, at least for a time, while others had appeared at very infrequent and irregular intervals. The number of volumes added during the year was 3,688, making a total of 89,963 in the library. In 1876, the year after its foundation, it possessed only 4,488 volumes. It is now the fourth in size among the medical libraries of the United States, being exceeded only by the Surgeon-General's Library at Washington, and those of the College of Physicians of Philadelphia and the New York Academy of Medicine.

A METHOD OF TREATMENT FOR CONJUNCTIVITIS.

BY

FREDERICK JEFFERSON, M.B. BELFAST,

CAPTAIN R.A.M.C.(S.R.),

OPHTHALMIC SPECIALIST — STATIONARY HOSPITAL;

AND

W. E. M. ARMSTRONG, M.A., M.D. DUBLIN,

CAPTAIN R.A.M.C.(T.C.),

OFFICER COMMANDING — MOBILE LABORATORY.

THE treatment of conjunctivitis is an important problem for doctors in the region of the firing line. The ordinary treatment is sometimes ineffective and often slow, with the result that many valuable men in excellent general health are rendered incapable of service for considerable periods owing to the state of their eyes. What is wanted is a treatment which will be at once more effective and more rapid, and it is also necessary that it should be capable of ready application to large numbers of men, and under circumstances in which the facilities for applying even the most simple remedies may perhaps not be very great.

Some of the cases of conjunctivitis are traumatic in origin, others are dependent upon and secondary to some other diseased condition, but most of the cases appear to be simple bacterial infections of the conjunctiva, and so should be susceptible to treatment by ordinary recognized antibacterial methods.

Experience has shown that immunization procedures are peculiarly applicable to many eye inflammations. Gonococcal, tuberculous, and sometimes streptococcal infections of the organ often give most excellent results when treated with the corresponding vaccine. But simple uncomplicated conjunctivitis is apparently seldom due to any of these organisms, and its bacteriology is so inconstant that to apply vaccine therapy would hardly be practicable under war conditions. It is, however, safe to say that any conjunctivitis cases in which styes are present as a complication should certainly be treated with staphylococcus vaccine.

The value of an antiseptic would appear to depend largely, if not altogether, upon the histological position of the invading bacterial army. When the bacteria are superficially disposed, an antiseptic is the most obvious agent by which they may be destroyed. In this process the tissues themselves will suffer injury and death, but such cellular losses will be replaced from the practically illimitable resources of the body, while the superficially placed bacteria have no such reserves to draw upon. When, however, bacteria have penetrated more deeply and have established for themselves in the tissue labyrinth bases where no antiseptic can reach, they can keep up a continuous stream of recruits which, in a war of antiseptic attrition, will be as proof against extermination as the cells of the organ they have invaded. In such a case antiseptics are not only useless but probably harmful, for by devitalizing the tissues they hinder the physiological forces from trying to accomplish the bactericidal effect which the antiseptic itself has no hope of accomplishing.

In conjunctivitis the inflammation is placed about as superficially as it is possible for any inflammation to be. It is the condition above all others in which we might expect an efficient antiseptic to produce good results. Now the substances used for the treatment of conjunctivitis are, as a rule, more distinguished for their astringent than for their antiseptic properties. We thought it would be interesting, and probably profitable, to try the effect of a remedy in which the antiseptic prevailed over any other action, and after some deliberation we chose enzol solution as the reagent best suited to carry out the idea, for the following reasons: (1) It is a most powerful antiseptic; (2) it seems strangely non-irritating to the tissues, almost as though it might imitate faintly with regard to bacteria the action of salvarsan with regard to a more developed form of microbe life; (3) it has apparently already given good results in the hands of some reliable workers in the field of general surgery, though, so far as we know, it has not yet been used in infections of the eye.

The investigation was carried out in the following manner:

Acting on advice kindly furnished by Professor Lorrain Smith, we commenced with a solution of eusol ten times more dilute than that used in the treatment of wounds. It speedily appeared, however, that this was too weak and that a solution about five times more dilute than the normal strength used for wounds gave the optimum effect in the treatment of conjunctivitis. Every second case of conjunctivitis was treated by irrigating the conjunctival sac freely three times a day with eusol; the other cases were treated with boric acid and zinc sulphate solution, as being probably the commonest of routine methods.

We took the cases absolutely in the order that they happened to arrive from field ambulances. The only thing that was done in the way of selection was to exclude from the experimental group those cases in which any complications coexisted with the inflammation of the conjunctiva. Cases of blepharitis, corneal ulceration, trichiasis, entropion, and ectropion seemed to us to present incalculable elements the inclusion of which would be likely to lead to ambiguous and uncertain conclusions.

One hundred cases were treated in this comparative manner. Of these 100 cases, the 50 treated with eusol took an aggregate time of 303 days to cure. The cases treated by boric acid and zinc took 448 days before they were fit for duty.

The employment of eusol therefore resulted in the saving of many days in the treatment, the average time required for a cure with eusol being 6.06 days, as against the average time of 8.96 days required to get the same result with boric acid and zinc treatment.

It was further apparent as the result of our work that, apart from any gain in time, eusol might yet be a very useful alternative measure for the treatment of conjunctivitis, for in six cases it succeeded in effecting a rapid cure of the disease where boric acid and zinc had proved unsatisfactory.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INTUSSUSCEPTION OF THE SMALL INTESTINE DUE TO FIBROMYOMA: EXCISION: RECOVERY.

The following case appears worthy of record for several reasons. Fibromyoma of the small intestine is rare, especially as the cause of acute following chronic intestinal obstruction in an elderly patient.

A thin lady, aged 50, had been failing in health and having colicky pains and indigestion on and off for six months. She got suddenly very much worse on December 7th, 1915. She vomited frequently, and on December 12th brought up bilious and brown offensive material. Euenata had at first brought away large masses of scybala, but without much relief. The patient had been more or less constipated for years, but she had been much worse of late. Dr. Clowes saw several coils of small intestine across the middle of the abdomen, and felt a hard lump varying in consistency to the left of the umbilicus. He did not think this was faecal, as it persisted after the enemata. His diagnosis was obstruction of the small intestine, probably due to growth. There was no blood in the results of the enemata, but some slime came away with one of them. When I saw her at Colchester, on the evening of December 13th, she looked exhausted and shrunken, but not very ill.

Operation.

Dr. Worts gave the anaesthetic, and Dr. Clowes assisted. A long incision was made through the middle and inner third of the right rectus. I at once felt an intussusception in the small intestine, probably about the middle of the ileum. It was about 8 in. long, and its apex was hard, and thought to consist of a polyp or carcinoma. Very gradually and gently the intussusception was reduced. As the last bit was released a depression was seen on the wall of the bowel, which indicated the attachment of the growth. The latter could now be well felt and moved inside the bowel. It was polypoid, but with a broad attachment, and was 2½ in. long and 1 in. in diameter. The intestine at and just below the growth was grey and thin; therefore I resected about 6 in. of it with the growth, and joined up end to end with two continuous sutures of fine black thread. The intestine above was greatly hypertrophied, and also considerably dilated, probably to twice the natural size. The abdomen was closed in layers with catgut and mass salmon-gut sutures in the usual way. The operation lasted about forty-five minutes. There was no shock at the end. She was given a rectal saline with 30 grains of aspirin immediately afterwards.

A letter from Dr. Clowes, dated January 30th, 1916, stated that the patient had done very well.

A report from the Clinical Research Association stated that "the tumour is composed of bundles of smooth muscle with a very small amount of fibrous stroma. It is not malignant, and has the general structure of a fibromyoma."

Recovery after resection at the end of six days' complete obstruction of the small intestine is uncommon. Resection seemed to be the best treatment, for even if the innocent nature of the tumour had been certain at the time of the operation, excision of the polyp would have involved cutting into the damaged bowel at its mesenteric border. It seemed better to remove the seriously damaged part. The question of drainage of the distended bowel above arose, but in view of the high position of the obstruction this was not thought necessary.

R. P. ROWLANDS, M.S., F.R.C.S.,
Surgeon to Guy's Hospital.

DUODENAL AND JEJUNAL ULCERS.

SIR J. BLAND SUTTON says (February 19th, p. 272) that surgery has evolved a new ulcer in the jejunum. He says also that "with an unobstructed pylorus gastro-jejunosomy cannot be relied on to cure a chronic duodenal ulcer . . . as it exposes patients to the discomforts and risks of regurgitant vomiting and jejunal ulcers . . ."

I hold that all ulcers in that region after gastro-jejunosomy are due simply to faulty technique. I fail to see the necessity for pylorotomy in duodenal or pyloric ulcers.

I have shown in my publications in the BRITISH MEDICAL JOURNAL of April 25th and July 25th, 1914, what is, in my opinion, the best operation for duodenal and pyloric ulcers—namely, a posterior gastro-jejunosomy with an entero-anastomosis in every case, done at the same time.

I have had a large experience in this operation, and have had no deaths and no jejunal ulcers occurring afterwards, and no unpleasant symptoms of any kind whatever.

The diagram shows the completed operation referred to.

PROCIDENTIA UTERI IN A NULLIPARA.

In the JOURNAL of February 5th, p. 218, in a letter on "Dystocia due to Constricted Os," Dr. W. E. Fothergill of Manchester says that "nulliparous women do not have procidentia uteri (the final or complete stage of prolapsus uteri)." Three years ago I met with a case of complete prolapsus uteri in a woman aged 20, unquestionably a nullipara. The condition had existed for about five months, and was accidentally discovered by her mother, who brought her to me. The vulvar ring had contracted behind the extruded corpus uteri, and an anaesthetic was needed before reduction could be effected. Here there was no overgrowth of the cervix. Cervix and body were both normal in size. It was a case of simple uncomplicated procidentia uteri in a nullipara. She was the daughter of a small farmer, and the condition was attributed by her mother to the carrying of heavy loads of farm produce. A pessary was put in; it was removed a few months afterwards, and, so far as I know, the ailment has not recurred.

Ballinalee, Edgeworthstown.

J. F. KEENAN, M.B.

Reviews.

ROENTGEN DIAGNOSIS IN GASTRO-INTESTINAL DISEASE.

GEORGE and LEONARD, in their book entitled *The Roentgen Diagnosis of Surgical Lesions of the Gastro-intestinal Tract*,¹ have relied largely on 368 illustrations to demonstrate the conclusions they have arrived at in diagnosing these conditions. The proposition they advance, put shortly, is that in pathological gastro-intestinal conditions the clinical evidence is so superficial and inaccurate that it can be, and ought to be, put on one side, and the diagnosis made on the x-ray findings alone. The case they make out is very striking. The construction of the book is interesting. It is divided into nine sections; each is prefaced by a very short summary of the authors' technique and conclusions, and this is followed by a large series of radiographs—fine ones, and admirably reproduced—demonstrating the points on which diagnostic reliance is placed. No clinical findings and no history are given—merely the age and sex, the manner in which the radiograph was made, the Roentgen diagnosis (pointing out the variations from normal on which it was based), and the operative findings. As in by far the larger proportion of the cases an operation followed on the diagnosis, this manner of demonstration is very convincing.

The nine sections are arranged as follows: After describing the normal stomach, the conditions dealt with are gastric ulcer, gastric new growth, the duodenum, the gall bladder, the small intestine, the appendix, the large intestine, and diverticulitis.

An important point, on which great stress is laid, is that the indirect method of arriving at x-ray conclusions (that of the Continental school of workers, in which the standard thick meal is used, and in which the roentgenoscopic and clinical signs are grouped together for the purpose of diagnosis) is altogether wrong in principle. The meal should be of bismuth subcarbonate and buttermilk, and the diagnosis, without any reference to anything else, should be based entirely upon the x-ray appearances seen and recorded on a number of plates. Perhaps the most striking chapter is, with its illustrations, that on duodenal ulcer; without accepting all that the authors claim, it is quite evident from what is shown, that this direct method, as it is termed, gives a far greater number of correct diagnoses than the indirect, or inferential, method. The radiographs showing the departures from normal in the duodenal shadow due to ulcers, the presence of which was proved by subsequent operation, are very convincing.

Some slight criticism we must make. In the chapter on the normal stomach several plates are described as "normal stomach: dilatation and ptosis"; to describe as normal a stomach showing these conditions is misleading. Under the head of Roentgen conclusions we find "hypernephroma causing a pressure effect on a normal stomach"; how can the diagnosis of hypernephroma be a Roentgen conclusion? A further error is to describe one plate as showing the pressure effects on the "greater curvature" of an ascending colon. Taken as a whole the book is the best which has yet appeared on the subjects it deals with, and is one which every x-ray worker should study carefully.

TREATMENT OF INFECTIOUS FEVERS.

In his exhaustive monograph on *The Treatment of Acute Infectious Diseases*² Dr. MEARA of New York goes very thoroughly into the nursing, dieting, and therapeutics of thirty three of the commonest infectious fevers, excluding tuberculosis and including a few diseases, such as dengue, leprosy, and psittacosis, that are rare in this country. The text is clearly written and admirably arranged; at the end of each chapter a headline summary of the procedures advised is given for convenience of reference. In the treatment of rheumatic fever Dr. Meara relies upon the exhibition of large doses of sodium salicylate combined with twice as much sodium bicarbonate, and he describes the drug, introduced by MacLagan in 1874, as a boon. In

the treatment of whooping-cough he gives antipyrin the first place, belladonna the second. In the treatment of laryngeal diphtheria he includes a description of the processes of intubation and debubation, written by Dr. M. C. Hill, but for tracheotomy refers his readers to surgical textbooks. Dr. Meara writes exhaustively upon the subjects with which he deals, and is well up to date. His book should be consulted by all medical men who are in doubt as to the varieties of treatment that may be employed in the management of cases of the acute infectious fevers and their complications.

An excellent handbook of *Fever*³ has been published by Dr. J. CAMPBELL McCURE for the use of students and general practitioners of medicine. First and foremost, it is a practical book; pathology, epidemiology, and bacteriology do not bulk very large in its pages: Twenty-five fevers are included as likely to be met with by practitioners in the British Isles; only seven of them are characteristically diseases of tropical or subtropical regions. Plenty of space is given to diet and treatment, a feature for which all who are responsible for the management of fevers will be grateful to the author. Tuberculosis of the lungs is included. Dr. McCure's book may be warmly recommended to all students and practitioners of medicine.

HOSPITAL CONSTRUCTION AND ADMINISTRATION.

THE second edition of Dr. MACKINTOSH's admirable book on the *Construction, Equipment, and Management of a General Hospital*⁴ has been revised, and enlarged by the addition of a chapter by Mr. John Wilson, architectural inspector of the Local Government Board for Scotland, on the construction of semi-permanent hospitals such as are called for by the war. The author, as is well known, has the Glasgow Western Infirmary to his credit. His book is an ordered exposition of the latest principles in hospital design to which experience has led him. It is therefore to a large extent an account of buildings to be found at this infirmary. Dr. Mackintosh would build a modern general hospital in blocks and units. The book begins with an account of the gatehouse or admission block for all the patients who come to the hospital, with its casualty rooms, emergency wards, suite of rooms for the casualty officers who should be always on the spot, and numerous other offices. The out-patient unit, described in a later chapter as a singularly complete and sumptuous department, is quite distinct; here the patients are first sorted and distributed to the various special departments in which they may require treatment. The in-patients are treated in units, which may be either medical, surgical, or special. The medical unit contains 22 male and 16 female beds; the surgical unit has also a third ward with 14 beds for accident cases; all the units have, in addition, a couple of side wards, each with a pair of beds for cases requiring isolation. The surgical units have each their own operating theatres and classrooms. Dr. Mackintosh makes a special point of having a bedroom, bathroom, and sitting-room in each unit for the house officer in charge, who thus lives in the midst of his patients, but for meals and recreation has the run of messroom, billiard-room, smoking-room, and the like, in common with all the other house officers. The resident staff have no food in their private apartments. Each unit has a further liberal supply of other rooms and offices to make it complete; there are three beds per unit of nursing staff, and each ward has a ward maid, as has the operating theatre. Other chapters in the book deal with the design of hospital kitchens, laundry units, methods of heating, the nurses' accommodation, and provision for cases of nervous and incipient mental disease. The Nurses' Home at the Toronto Hospital for Sick Children is described as probably the best in existence, and is detailed and figured; the building cost £28,000, and appears to accommodate 63 nurses. Dr. Mackintosh gives full lists of the fittings required in the various hospital units and departments, and many illustrations of these are inserted; a number of plans at the end of the book do much to make the designs plain. No key is given to the numbers appearing in the plans of the

¹ *The Roentgen Diagnosis of Surgical Lesions of the Gastro-intestinal Tract*. By A. W. George, M.D., and R. D. Leonard, A.B., M.D. Boston: The Colonial Medical Press. 1915. (Dbl. roy. 8vo, pp. 291; 357 figures. 10.00 dols. in U.S.A.; £2.5s. in England.)

Toronto nurses' residence, though this could easily have been done on page 151. The book is full of invaluable practical information, the harvest of years of experience. It should be in the hands of all who have to do with the design of any hospital larger than a cottage hospital.

NOTES ON BOOKS.

THE fifty-second edition of Herbert Fry's *Royal Guide to the London Charities* gives a brief and admirably clear survey of the metropolitan charities of all sorts, in alphabetical order, and with indexes that enable cross-references to be made with ease. The book is up to date and accurate. It should be in the hands of donors as well as beggars, being designed for those who wish to give with due discrimination as well as for those who have some lame dog to help over a stile. The editor's preface sets out clearly the present need for thrift in all public and private expenditure, yet emphasizes the still greater need for keeping the two or three thousand charities he tabulates at full work, unstinted of subscriptions. With these views we heartily concur.

Russia is a country to which few British travellers have penetrated in the past, no doubt in consequence of its remoteness, the long sea journey that usually leads to it, and the difficulties of the Russian tongue and the Cyrillic alphabet. In the future it is to be hoped and confidently expected that the calls of commerce or pleasure will induce a far greater number of the inhabitants of Great Britain to go travelling in the great country of our gallant ally. A Russian grammar and reading book on Hugo's simplified system⁶ do all that can be done to make the language problem easier for a race notorious, as is ours, for its poor skill in the tongues of foreign nations. We have received a copy of Part I of the grammar and reader, each to be completed in three parts, and we commend them to the favourable notice of our readers.

MEDICINAL AND DIETETIC PREPARATIONS.

Horlick's Malted Milk Lunch Tablets.

WE have recently received from the Horlick's Malted Milk Company a specimen tin of Horlick's malted milk in tablet form, specially designed for the use of the army and navy. The tablets are sent out in tightly closed flat tins of a convenient size for carrying in the pocket, and are stated on the tin to contain full nourishment for one man for twenty-four hours. The tin supplied to us contained 79 tablets, having a total weight of 107.5 grams (3.8 oz.). From an analysis of Horlick's malted milk made by us some years ago, the weights of sugar, fat, protein, and ash contained in the whole contents of the tin are as follows:

		Approximate Calorific Value in Large Calories.
Protein (from total nitrogen)	15.4 gm. \times 4.1	= 63.1
Fat	7.8 gm. \times 9.5	= 72.5
Reducing sugars calculated as maltose	59.7 gm. \times 4.1	= 244.8
Ash	3.9 gm.	
Total		380.4

The above, however, does not give quite the total value of the preparation, since a certain proportion of the carbohydrate is present in a form other than that of reducing sugars; probably the total calorific value would be about 450 calories. The total calorie value of the ration of the British soldier in this war is calculated to be from 4,500 to 5,000 calories, and that of the German soldier about the same, or possibly a little less. It is evident from the above figures that the contents of one of these tins can only be regarded as containing sufficient nourishment for a man for twenty-four hours, unless it be as an emergency ration to tide over some special period of difficulty. The tablets are palatable and may be sucked in the same manner as an ordinary sweetmeat.

A BILL was introduced into the United States Congress on January 4th providing for the establishment of a fund of £2,000,000 for the construction of drainage works to reclaim wet, overflowed, and swamp lands. This is intended as a measure for the prevention of the dissemination of malaria and other diseases.

THE REPORT OF THE ROYAL COMMISSION ON VENEREAL DISEASES.

THE Report of the Royal Commission on Venereal Diseases was issued on March 2nd. It is signed by all the Commissioners, subject to reservations as to prisoners and poor law patients, by Sir Kenelm Digby and Canon Horsley.

The Commission was appointed on November 1st, 1913, "to inquire into the prevalence of venereal diseases in the United Kingdom, their effects upon the health of the community, and the means by which those effects can be alleviated or prevented, it being understood that no return to the policy or provisions of the Contagious Diseases Acts of 1864, 1866, or 1869 is to be regarded as falling within the scope of the inquiry." Eighty-five witnesses were examined, to whom 22,296 questions were put.

I. INTRODUCTION.

In the first section of the report previous action by the State is noted. This was concerned with the control of venereal disease in the army and navy. The Contagious Diseases Act of 1864 aimed at preventing venereal diseases by subjecting prostitutes to surveillance and medical examination. Amending Acts were passed in 1866 and 1869.

A Medical Committee and Parliamentary Committees appointed to inquire into the working of the Acts in 1868 and 1869 recommended the cautious extension of the system of the Acts.

Formidable opposition to the Acts led to the appointment of a Royal Commission in 1870, which recommended the discontinuance of the periodic examination of prostitutes, but otherwise was in favour of the system of the Acts. The House of Commons Committee of 1879, appointed for the same purpose, was almost equally divided in opinion, but the majority reported against the repeal of the Acts. In 1883 the examination of prostitutes was abolished by Order, and in 1886 the Acts were repealed.

The Commissioners were precluded from "considering the policy of these Acts, but they wish to place on record their view that the evidence they have received, which includes that of several Continental experts, points to the conclusion that no advantage would accrue from a return to the system of those Acts. So far from this being the case it is to be noted that the great improvement as regards venereal diseases in the navy and army has taken place since the repeal of the Acts." They concur in the conclusion of the Advisory Board of the Army Medical Service of 1903: "Better results are likely to be obtained by the diffusion of the knowledge of the serious consequences of these diseases and the provision of effective treatment for both sexes under conditions to which no stigma is attached."

Other departmental inquiries are noted which showed the grave effects upon the poor caused by the diseases, and the totally inadequate provision for their treatment.

Description of Venereal Diseases and Means of Transmission.

After a note on the introduction of syphilis into Europe there is the following significant passage:

"Our present knowledge of the cause of syphilis and the great advances which have been made in its diagnosis and treatment is of less than twelve years' duration; it may be said to have commenced with the successful inoculation of animals by Metchnikoff and Roux."

The clinical description in this section is admirably written.

II. PREVALENCE.

Many pages in the second section are devoted to the critical examination of the statistics presented by various Government departments, and private persons. Few of them satisfactory, only the figures from the army and navy can be considered reliable.

The Registrar-General gave the death-rate from syphilis for many years, and added "the worthlessness of the returns as an absolute statement of the number of deaths from venereal disease scarcely requires demonstration." Deaths from syphilis are not so certified from fear of hurting the feelings of relatives, and large numbers are ascribed

* Royal Commission on Venereal Diseases. Final Report of the Commissioners. [Cd. 8189.] Price 1s. 11d.

to other causes now known, or beginning to be known' to be due to syphilis—for example, locomotor ataxia, general paralysis, and aneurysm of the aorta. Taking into account the curves of syphilis and aneurysm and the rise of the population, Dr. Stephenson is inclined to believe in a "genuine fall" in the mortality from the disease. On the other hand, the number of diseases known to be closely associated with syphilis has largely increased in the same period, while the reluctance to certify syphilis as a cause of death has probably not diminished. "We are therefore doubtful whether there has been any reduction in the mortality justly attributable to syphilis in recent years."

The Scottish figures correspond with those of England and Wales. Ireland, judging by the figures of the years 1901-10, shows an increase of 70 per cent. in deaths from syphilis; but it was explained that "the increase was more apparent than real," and could be traced to better certification and to "the system of direct communication with the doctors."

In the navy the incidence of syphilis has declined from 48.92 per 1,000 in 1905 to 28.93 in 1912. Gonorrhoea shows a higher rate than syphilis and no distinct improvement is exhibited. The Mediterranean and Cape stations present the best records, the Home station the worst.

In the army the number of recruits rejected for syphilis has fallen from 0.63 per cent. in 1890 to 0.14 per cent. in 1911-12, and the decrease has been fairly uniform throughout this period. The fall in the proportion of rejections for syphilis has been far greater than that due to other physical disabilities. Since recruiting sergeants tell would-be recruits to get cured before they present themselves for medical examination, "these figures cannot be regarded as a conclusive indication of decreasing prevalence among the civil population." The returns for soldiers on home service show much improvement. The rate for all venereal diseases has fallen from 224.5 per 1,000 in 1888 to 56.5 in 1912; whilst all other diseases fell from 700.9 to 346.4. In the same period the percentage of venereal disease to the whole fell from 30.7 to 16.3. At first gonorrhoea and syphilis were practically equal in incidence, now their proportion is as 3 to 2. In India the prevalence of syphilis is slightly lower, and of gonorrhoea somewhat higher, than at home.

Professor Blaschko gave comparative figures "showing the incidence of disease in various European armies and navies, indicating a generally falling tendency, except in the navy of the United States." The figures for France and Germany show little change in the periods taken. "Assuming these figures to be directly comparable, which is probably not the case, the British army at home and in India shows higher figures than those of any other army included in the table; but the percentage of infected recruits is more than five times as high in Germany as in Great Britain, and Professor Blaschko considers that the prevalence of venereal disease in Germany is higher among the civil population than in the army, and higher than in Great Britain."

The Local Government Board's figures for the home population and general and Poor Law institutions are not very illuminating, owing to confessedly incomplete returns due to many causes. Perhaps the most instructive are the figures for ophthalmia neonatorum. The case-rate works out at 6.5 per 1,000 births; in urban districts it was 6.8, and in rural districts only 1.0, and it is thought that the difference corresponds to real difference in the incidence of the disease.

The prison returns are similarly unsatisfactory, and consist only of those obtained on specific occasions. In local prisons just under 2 per cent. of the prisoners showed clinical signs of venereal disease. But more noteworthy is the record that half of these diseased persons were discharged in an infective state. In convict prisons 17.04 per cent. presented signs of having had syphilis. In Borstal institutions for young prisoners between the ages of 16 and 21 specially selected as likely to become habitual criminals, of 941 inmates 16.26 per cent. presented one or more signs of congenital syphilis, and there were also five cases of acquired syphilis. "The figures were carefully compiled, and may indicate that mental defects due to this cause conduce to some extent to produce the class of prisoners which come within the scope of these institutions." The Scottish figures are similar, and again 56 per cent. of the diseased were discharged in an infectious state. The Irish figures are much smaller, but there is

the same tale of more than half the diseased discharged whilst still in an infectious state.

The Lunacy Commissioners gave the figures of the incidence of general paralysis of the insane, based upon the pauper admissions to the asylums during the five years 1908-12. The totals gave rates of 3.07 for males and 0.55 for females per 1,000 respectively to the population at the census of 1911. Cases are far more numerous in towns than in rural areas. In the London asylums the total percentage due to general paralysis is a little over 8, and the male admissions a little over 15, indicating the considerable part played by syphilis in peopling the London asylums.

Certain special investigations are quoted. Dr. Fildes summarized the results of 1,002 Wassermann tests made by Dr. Bulloch among patients at the London Hospital specially selected and being treated for reasons wholly unconnected with syphilis; 10.3 per cent. of the males and 5.1 of the females gave positive reactions. Congenital syphilitics were not included.

Sir John Collie submitted the results of the clinical examination of 1,119 cases of accident and of 557 healthy persons examined for the purposes of their work. Amongst these there were 60 cases (including 4 of gonorrhoea), or 3.58 per cent., of venereal disease. He submitted the blood of 491 healthy persons to Dr. Mott for the Wassermann test; 46, or 9.36 per cent., gave a positive reaction. "The investigation dealt only with a somewhat superior class of workers. The prevalence of venereal disease which is indicated seems higher than might have been expected."

The Commission caused the serum test to be performed on all the cases admitted into fourteen asylums, representing all classes of the community, for three months in 1914, with the result that 15.4 per cent. gave a positive reaction.

The investigation of Poor Law patients carried out by Dr. Mott is of interest. Epileptics gave 7.4 per cent. positive reactions, insane non-paralytic patients 8.4 per cent., Poor Law patients in infirmaries in London 19.9 per cent., feeble-minded children 8.1 per cent. Mothers of newborn infants in Shoreditch gave 19.7 per cent. positive reactions, in St. Pancras only 6.6 per cent.; in the Shoreditch cases 29 of the mothers were unmarried, and these gave 27.6 per cent. positive reactions.

(To be continued.)

THE RETRENCHMENT COMMITTEE.

FINAL REPORT.

THE committee on retrenchment in the public expenditure, of which the Chancellor of the Exchequer is chairman, has presented its final report, dated February 21st, 1916. It was appointed to inquire "what savings in public expenditure can, in view of the necessities created by the war, be effected in the Civil Departments without detriment to the interests of the State." Its scope, therefore, did not include expenditure on army, navy, or munition services, and even as regards the civil departments it was warned that questions of policy already decided by Parliament should be avoided as far as possible, as it would be impracticable at the present time to introduce controversial legislation.

The first section of the report states that the increase of civil expenditure in recent years has been enormous and unprecedented—from £32,000,000 in 1895 to £90,000,000, an increase of nearly 200 per cent. The increase is due almost entirely to new grants, or new administrative work resulting from legislation or parliamentary policy. Thus, of a total increase of £40,000,000 on the Civil Service estimates, the grants required for old age pensions amounted to £13,500,000; for national insurance and labour exchanges to £9,500,000; and for education to £12,000,000.

Measures already taken to ensure economy are enumerated. The first attempt was not particularly successful, inasmuch as the estimates for the civil service and revenue departments for 1915-16 showed an increase of £205,000. The corresponding estimates for 1916-17, excluding the cost of new services required entirely for war purposes, show certain increases and certain decreases, but the net decrease is estimated to be over £3,000,000, apart from the large reduction of capital expenditure not shown in the

estimates effected by curtailing the issue of loans to local authorities—a reduction at the rate of over £4,000,000 a year—and in other ways.

The report makes certain recommendations for further economies, and the following notes apply to such as have reference to matters of medical interest.

Factory Inspection and Certifying Surgeons' Reports.

After commenting on the rapid growth of expenditure for the inspection of factories and mines, and apparently accepting the view that it cannot be reduced, the committee makes the following recommendation with regard to reports of certifying surgeons on accidents:

We understand that the reports of certifying surgeons on accidents, which cost £12,500 per annum, are now of little value, and entail in all serious cases a duplication of the reports made by the inspectors. The Committee on Accidents in Factories recommended that legislation should be obtained to enable them to be dispensed with, and we concur in this proposal.

The Board of Control.

This board consists of a chairman and ten commissioners, with salaries rising to £1,500 a year. The committee considers that an equally efficient organization could be secured by a board of not more than five members, and by the substitution for the others of deputy commissioners or inspectors with maximum salaries of £800, as provided by the Mental Deficiency (Scotland) Act. In England legislation would be required to make the change, but the committee recommends that any vacancies arising in the present board should not be filled up. It also recommends that the contributions towards the cost of institutional treatment for mentally defective persons should be reduced except in urgent cases, and a limitation on the cost of maintenance fixed in all cases.

The Local Government Board.

The vote for this department has grown, in round numbers, from £221,000 in 1905–6 to £362,000. The committee recognizes that this increase is mainly explicable by the increased attention paid to medical, sanitary, and housing problems, but recommends that a special inquiry into the administrative staff of the board should take place. The committee then proceeds to make the following reference to fees for the notification of infectious disease:

(Notification.)

We recommend that the Local Government Board should take immediate steps to revise the fees paid to medical practitioners for the notification of infectious diseases. At present the medical practitioner receives a fee of 2s. 6d. if the case occurs in his private practice, and 1s. if the case occurs in his practice as medical officer of any public body or institution. The total sums paid for notification fees in England and Wales in each of the five years ending 1911 was approximately £30,000; but since that time the total cost has steadily risen, and a further substantial increase of cost will probably result from the recent order requiring the notification of cases of measles and German measles.

As doctors have now become familiar with the work of notification, and so many additional diseases have been added to the list since the fees were originally fixed, we consider that the time has come for reducing the 2s. 6d. fee to 1s. The amount of labour involved in filling up the notification form is, we understand, very slight indeed, and a fee of 1s. would seem to be adequate remuneration for the purpose.

The Board of Education.

The committee recommends that children under 5 should only be admitted to schools in special cases, and that an inquiry should be instituted into the possibility of introducing a normal minimum age of 6.

With regard to medical work the report contains the following paragraph:

Medical Work.

We understand that the activities of the Board of Education and the Local Government Board overlap to a considerable extent as regards arrangements for the health of mothers and young children under school age, and that the two departments have found it very difficult to settle a clear line of demarcation between their respective spheres. It is in our opinion most unsatisfactory that two Government departments should deal with what is essentially the same problem, and it can only lead to disputes and an unnecessary inflation of staff.

It is a difficult problem to decide between the two departments in this matter; but as long as there continue to be two medical branches, we consider that, in all the circumstances, the only satisfactory solution would be that the control of all institutions (including schools for mothers and day nurseries)

providing in any way for the welfare, from the health point of view, of mothers or children under school age should be handed over by the Board of Education entirely to the Local Government Board for them to administer in connexion with their public health work generally, and in co-operation with the local health authorities. This plan is being adopted in Scotland, and we see no satisfactory alternative to it in present circumstances. The Board of Education could of course still continue to pay grants, if necessary, in respect of purely educational classes in cooking, needlework, etc., held in any of the institutions or by local education authorities elsewhere, but the duties of the Board's medical branch should, in our opinion, not extend beyond the supervision of the health work carried out for children of school age who are being educated in elementary, etc., schools under the Board's control.

The above arrangement would, of course, be merely a make-shift, and it is very desirable in our opinion that the first opportunity should be taken of amalgamating the medical branches of the two departments altogether.

National Insurance.

The committee does not make any definite recommendations with regard to the amalgamation of the several boards of commissioners; it considers that the centralization of the whole service does not appear to be practicable, but thinks that it should be possible to devise a scheme which would safeguard national interests and sentiments without the retention of so many as twenty-one commissioners with salaries amounting to £24,600 per annum.

An analysis of the cost of the central administration shows that the rate per thousand insured persons is as follows: England, £28; Scotland, £36 14s.; Wales, £51; Ireland, £59 14s. While recognizing that difference in the numbers and distribution of the population would not unnaturally result in a smaller charge per head in England than in other parts of the United Kingdom, the committee is "not aware of any sufficient difference of conditions between Wales and Ireland on the one hand and Scotland on the other to justify the much heavier charges incurred by the Welsh and Irish commissioners."

The committee expresses the opinion "that much could be done to reduce the expense of the Act, and to increase the sums available for benefit by simplifying its more elaborate provisions." Something has been done in this direction by departmental action, but before other alterations from which larger savings would accrue legislative sanction would be necessary. The committee's reference to this subject concludes with the following sentences:

But the evidence which we have taken showed that few, if any, of these proposals would be absolutely non-contentious; and it was quite clear that the questions which afford the best field for economies—the system of medical and sanatorium benefit, the constitution of insurance committees, the approval of small societies, etc.—were acutely controversial. We could not have dealt with any of these questions without going far beyond the terms of our reference, and we have come to the conclusion that the best results would be obtained by a special inquiry into the whole administration of the Act with a view to its reorganization on a simpler basis.

In the concluding section of its report the committee expresses the opinion that all Government departments which require local authorities to furnish statistical or other reports should carefully revise their requirements without delay with a view to simplification, and that this policy should be maintained and extended after the war.

A DISCUSSION on food inspection, standards of purity for food supply in war time, and the utilization of condemned stores, will be opened by Dr. J. Wright Mason, M.O.H. Hull, at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Thursday, March 9th. The chair will be taken by Sir William Collins at 4.15 p.m.

DR. ROBERTSON, Health Commissioner of Chicago, has found (we learn from the *Journal of the American Medical Association*) a philanthropist to finance for a year his scheme of a public health magazine to be distributed free; the issue is to be about 100,000 copies a month.

IT was announced in the *BRITISH MEDICAL JOURNAL* of January 29th that the *Giornale Internazionale delle Scienze Mediche* had been discontinued owing to the death of the publisher, Enrico Detken. Its place has been taken by *La Medicina Pratica*, the first number of which appeared on January 31st under the direction of Professor Luigi Maramaldi, lecturer on therapeutics in the University of Naples, who was for many years editor of the defunct periodical. The new journal is for the present a monthly, but will be published fortnightly "as soon as barbarism is humiliated and right restored."

British Medical Journal.

SATURDAY, MARCH 4TH, 1916.

RECRUITMENT OF DOCTORS IN ENGLAND AND WALES.

WE are officially informed by the War Office that, in accordance with their previous announcements, doctors who have undertaken to accept a commission in the Royal Army Medical Corps (if offered one) will not be taken for general service; and therefore that any doctor in England and Wales who (whether attested under the Derby scheme or not) has enrolled under the scheme of the Central Medical War Committee or has offered his services in the Royal Army Medical Corps direct to the War Office should, if he receives a notice paper from a recruiting officer calling him up (whether by reason of attestation or under the provisions of the Military Service Act), return it to the recruiting officer, together with his certificate of enrolment, or the War Office acknowledgement of provisional acceptance, as the case may be; and the notice will then be cancelled and the practitioner remain in the Reserve until selected for a commission in the Royal Army Medical Corps.

Doctors will not be called up, whether by reason of attestation or under the Military Service Act, until after March 31st, 1916.

Doctors in England and Wales who have not undertaken to accept a commission (if offered one) in the Royal Army Medical Corps will, when called up (whether by reason of attestation or under the Military Service Act), have the same rights of appeal for exemption as men who are not doctors; but all cases coming before the Central Tribunal will be decided by that tribunal after receiving advice from the representative committee of the medical profession specially recognized for the purpose.

Analogous arrangements will obtain in respect of doctors in Scotland.

The importance of the above official information will, we have no doubt, be fully appreciated, and the question may be asked:

What, then, is the course that a medical man of military age should now take to ensure that his services shall be used in the way that shall best serve the interest of the nation?

In the first place, we would advise him, if he has not already done so, to enrol at once—that is, send in his name to the Central Medical War Committee, 429, Strand, London, W.C., or to the Scottish Medical Service Emergency Committee, Royal College of Physicians, Edinburgh, undertaking to accept a commission in the Royal Army Medical Corps, if offered to him, realizing that, if he takes this course, all his circumstances—public and, so far as he wishes, private—will be considered with the utmost care by a professional body before it is decided whether he should in fact be called upon to take a commission.

In the second place, every medical man who has already enrolled should make it his business to point out to every one not enrolled that it is his duty and advantage to do so at once. It is to his advantage because, when he receives a notice paper from a recruiting officer calling him up, the production of his certificate of enrolment will ensure that the notice shall be cancelled and that he will remain in the Reserve, thus securing that, as explained above, his case shall be fully considered by a professional body before it is decided whether he should be called upon or not. It is his duty, because it is only by having before it provisional offers of service from the general body of medical men that the Central Committee can arrange an equitable distribution of military and civilian services throughout the country.

An interesting case of a medical practitioner on the staff of a well known hospital applying for exemption from service was heard at a local tribunal last week. The tribunal, according to the report before us, granted him one month's extension and expressed the opinion that the applicant ought to go. It would appear, therefore, that this gentleman might shortly have found himself in the combatant ranks of the army had he not, as we hear is the case, since enrolled himself, so that his case, as above explained, will now be dealt with by the professional body.

THE STATE AND THE CARE OF THE CHILDREN.

IN recent issues we have reviewed the Report of the Medical Officer for the Board of Education for the year 1914. Blue books are not seductive reading at any time; in war time we fear few will be attracted to the first-hand study of this report. Yet there is no production that is more pertinent to these grave times, and to the fearful destruction of life that has reduced, and must still more reduce, the virility of our people. For the report deals with the coming generation, and from this we must hope to rebuild the waste places of our homes.

The time was when education meant no more to the average citizen than a due instruction in the three R's. But here in a blue book we find the chief medical officer of the Board of Education dealing almost wholly with the production and preservation of life, for that, after all, is the meaning of schools for mothers, care committees, and the like. When the school medical service is viewed from this standpoint it takes an altogether different value in the national assets. The service is no longer merely an aggregation of inspectors who prow round the schools with eyes alert to find fault with curriculum, buildings, lighting, books, and the bodies of the children themselves; that work, truly falls to them, but they are now found to have a far more important sphere of action—a solicitude for the very fount of life.

With the war many of the medical officers have undertaken military service, and money grants have been cut off. Therefore much of the work must be curtailed, clerical work especially; the preparation of reports, even research work, must be foregone. But there should be no slackening of the residual and essential part of the school medical officers' work, the supervision of the schools in the interest of the common health, the prompt elimination and care of the obviously unfit, and the promotion by every means, official and voluntary, of a healthy motherhood and a well-born infant. The Board of Education has recognized in the most prompt fashion the necessities of the situation; it has freely permitted the release of

its medical officers for military service, and no red tape has hampered the revision of the orthodox procedure in regard to routine medical examinations.

The gain from the medical side of educational work may not be immediate, but it is certain and cumulative. We may take it that some part of the diminution of the infantile death-rate is to be credited to it. As Sir George Newman writes: "The decline in recent years in infant mortality-rate is providing broadly a direct saving of 20,000 lives per annum. This direct gain is mainly due to more enlightened mothering, the better care and management of infancy, and the effective treatment of infantile disease—all three contributions being due, generally speaking, to an improvement in the education and training of the mother in all that concerns healthy maternity and infant welfare." The school work done is no less impressive. In London alone in 1914 upwards of 194,000 children were examined; 101,000 were found to be in need of treatment and 86,000 received treatment. It is estimated that in England and Wales 1,900,000 children are examined each year, of whom 650,000 present remediable defect and 375,000 actually receive treatment. There is reason to take to heart Sir George Newman's aphorism, "To save child life is an axiom of State preservation; to remedy defect is an axiom of State economy."

One of the most interesting sections of the report deals with the schools for mothers. These institutions originated in voluntary effort; they are now recognized and subsidized by the State to the half of their expenditure, and many have been opened and are now worked by the local authorities. But the working of these schools affords a situation not without its humorous aspects. There are, besides many local authorities, two Government departments interested in them. The Board of Education takes a paternal interest and loosens its purse strings on their behalf in so far as they are schools for mothers, whilst the Local Government Board is willing to act as the foster mother of these self-same institutions and dole out something for their sustenance in so far as they are maternity centres. Each of these Boards issues regulations, and tells the workers in these institutions what features of their work it is that stimulates its affectionate interest, and at the same time states upon what score the needful money can alone be obtained.

The report of the Board of Education attempts to show that there is a difference in the ultimate work of these two governing bodies. "If the ultimate object of the efforts made be considered, a broad line of demarcation between the two can be established without much difficulty. Thus the institutions included under the title 'schools for mothers' have for their main objects the reduction of infant sickness and mortality by means of the education of the mother. They train the mother to keep her baby in good health through a common-sense application of the ordinary laws of hygiene. The training may be given by means of personal advice from doctor or nurse to individual mothers, by home visitation, and by means of collective teaching and systematic classes. 'Maternity centres,' on the other hand, have the health of the mothers and children as their main care. They provide medical advice and treatment for expectant and nursing mothers, and for infants and little children."

We may be particularly dense and lacking in appreciation, but we wholly fail to see any "broad line of demarcation" in "the ultimate object" of these two modes of action. The one has for a "main object the reduction of infant sickness and mortality," the

other "the health of the mothers and children as their main care." It is scarcely arguable that the means adopted to attain these ends are different, but to maintain that there is any difference in the end is to maintain a distinction without a difference.

Even the point that the education authority has nothing to do with the treatment of disease fails in practice, for in the discussion of "The Infant Consultation" we read: "If any treatment is provided, this should be incidental in character and limited to children suffering from minor and temporary ailments—an occasional grey powder, a little boracic ointment, etc." One is inclined to ask if the point of the order lies in the quantity of the ointment to be supplied. The fact is that the more the report tries to show that the Board of Education and the Local Government Board have separate functions in regard to these "schools for mothers" or "maternity centres," or by whatever other name they may be known, the more effective is the demonstration that there is no difference between the aim or the effective attainment of these two bodies; and in these times, when thrift and reasonable economy is a vital necessity, it would be well that the two bodies should compose their differences and put a single effort into a piece of work that is of inestimable value. The Retrenchment Committee in its last report goes somewhat further, for it recommends as a temporary expedient that the control of all institutions, including schools for mothers and day nurseries, providing in any way for the welfare, from the health point of view, of mothers, or children under school age, should be handed over by the Board of Education to the Local Government Board, to be administered in connexion with that Board's public health work generally and in co-operation with the local health authorities. The duties of the medical branch of the Board of Education should not, in the Committee's opinion, extend beyond the supervision of the health work carried out for children of school age who are being educated in public elementary schools. We are not sure that this proposal will prove to be non-contentious, for there is a good deal to be said for the transfer in the opposite direction. In any case, however, the Committee considers this arrangement merely a makeshift, and expresses the opinion that it is very desirable that the first opportunity should be taken of amalgamating the medical branches of the two departments.

Up to the present it would appear that the only effort for united action between the two departments has been the issue of a joint circular (No. 906, May 31st, 1915) in which the position of each department is set out; a hint is given that the institutions are to range themselves under one or other department for the purpose of grant earning, "though joint aid by both departments in exceptional cases is not precluded"; and the statement made that "questions arising under this Memorandum will be referred for investigation and decision to a joint committee of the two boards." Let us hope that the "questions arising" will be in such a continuous flow that the joint committee will ultimately become the single governing authority of these "maternity centres" and "schools for mothers."

RETRENCHMENTS.

THE Final Report of the Treasury Committee on Retrenchment in the Public Expenditure is a disappointing document, not so much because the retrenchments it recommends do not in the aggregate

amount to the cost of the war for a single day, but because of the failure to make plain what economies it thinks can at once be effected. The Committee was not instructed to consider the expenditure on army, navy, and munition services; nor was it allowed to consider the question of the payment of salaries to members of the House of Commons, though it has ventured to recommend the House to withdraw the subsidy of £2,600 a year which it has been in the habit for the last twenty-two years of voting towards the cost of its refreshment room. The Committee was also told that even as regards the civil departments questions of policy already decided by Parliament should be avoided as far as possible, "as it would be impracticable at the present time to introduce controversial legislation." The student of the report is left in some doubt whether the Committee considers that the recommendations it makes, the majority of which would require legislative sanction, do or do not come within the scope of the definition of "controversial legislation"; nor is it made plain what changes it thinks should at once be made and what must be deferred until after the war.

Speaking generally, it seems to have come to the conclusion that the country is over-inspected; it states that as a temporary measure some departments have arranged to curtail inspecting work to a large extent, and it recommends that this policy should be generally adopted as far as possible throughout all departments of the civil service.

Whether the proposal that children under 5 should only be admitted to elementary schools in special cases, and the suggestion that it may be possible to introduce a normal minimum age of 6, are to be considered matters outside the scope of controversy is not plain; it will be surprising if they prove to be so. The Committee definitely recommends—apparently for immediate action—the transfer from the Board of Education to the Local Government Board of the responsibility for medical work, except in public elementary schools, and that the first opportunity should be taken of amalgamating the medical branches of the two departments. This recommendation seems to bring us a step nearer to the ideal of a ministry of public health, although as matters now stand it is difficult to see how such a ministry could be placed on a logical basis without including national insurance, for the Act by which it was instituted is entitled "An Act to provide for insurance against loss of health and for the prevention and cure of sickness. . . ." The Committee was evidently itching to make some drastic recommendations with regard to the Insurance Act, but was told that few, if any, proposals which could be made for economy would be absolutely non-contentious, and that it was quite clear that the system of medical and sanatorium benefit, enumerated as among the questions which afforded the best field for economies, were acutely controversial. They were expressly excluded from the reference to the Insurance Finance Committee, which is instructed to report upon "any amendments in the financial scheme of the National Insurance Acts which experience of the administration of sickness, disablement, and maternity benefits may suggest as desirable, within the existing limits of contributions and benefits, and apart from further Exchequer grants." The Retrenchment Committee evidently does not favour further grants, seeing grave objections to departing from the principle that the benefits to be paid should be measured by the contributions received, including the automatic contribution from the Exchequer.

Two of the recommendations made by the Retrenchment Committee have a very direct, and it seems

possible an immediate, interest for the medical profession. The first is the proposal to reduce the fee for the notification of infectious disease occurring in a practitioner's private practice from 2s. 6d. to 1s.; the amount now paid for notifications of cases occurring in his practice as medical officer of any public body or institution. The reasons given for this recommendation are rather curious: first, that doctors have now become familiar with the work; secondly, that many additional diseases have been added to the list since the fees were originally fixed; and thirdly, that the labour involved in filling up the form is very slight. It does not seem to have occurred to the Committee that the fee is not paid for clerical labour, but for knowledge and skill. The other recommendation is that the reports of certifying factory surgeons on accidents should be abolished, mainly on the ground that in all serious cases they entail a duplication of the reports made by the factory inspectors. These two recommendations will call for the serious consideration of the British Medical Association and the profession in general, and we have therefore quoted them textually at page 347.

CRIPPLED SOLDIERS.

ST. DAVID'S DAY was celebrated by Welsh men and women in London by a great patriotic meeting in the Opera House in Kingsway, and, appropriately enough, since St. David is said to have been something of a physician, the occasion was taken to help the fund for providing comforts for the Welsh soldiers; for, as Lord Harlech, Colonel of the Welsh Guards, who presided, told the meeting, Wales has provided over 200,000 soldiers for this war. Another Welsh soldier, Sir Francis Lloyd, the General Officer Commanding the London District, made a stirring speech, but, before this, Major Robert Jones, F.R.C.S., of Liverpool, had paid fitting tribute to the manner in which the traditions of the Welsh troops were being maintained. One of his most impressive experiences had been to hear in the dusk, from a village close to the Welsh lines, the men coming back from the trenches singing as only the Welsh could sing. The story of sanitation at the front was like a fairy tale. The rude ploughed fields of twelve months ago had undergone a marvellous transformation at the touch of sanitary science, and now the sanitation of the war area in Northern France was better than that of any rural area in England. He concluded with a plea for the crippled soldier; to keep him from pain and poverty was a sacred charge upon the nation. Mr. Lynn Thomas made a strong appeal to the patriotism of Wales. He spoke of the teaching of St. David and his insistence upon the value of discipline. Were he alive to-day St. David would have sought to induce his countrymen to understand the importance of strict discipline to attain victory over the monstrous doctrine of might and frightfulness. Mr. Lynn Thomas dwelt on the urgent need and very crying call to go at once to the rescue of the tens of thousands of crippled men, victims of the war. He knew of cases in which young soldiers had been reported unfit for further service who, he believed, could be rendered fit by modern orthopaedic treatment. When it was remembered that the United States after the Civil War had about 400,000 cripples from their army, which was not quite so large as the British army to-day, the necessity would be apparent for immediate action in order to give wounded soldiers with crippling injuries the advantages of the newer principles of treatment. He had recently visited in France a hospital conducted by eminent American surgeons who confessed that they were confronted by new conditions in

crippled limbs and asked for new light. When it was given they expressed their warm appreciation of it. The head of the Army Medical Department at home was fully alive to the need, and was working hard to ensure that the new light should be made to shine upon the large number of crippled soldiers. The public should give its support. A special ministerial department should, in his opinion, be formed to deal with the restoration of crippled men so that they might again become useful citizens. He appealed to the Welsh members of Parliament to render all assistance in their power to hasten the desired consummation.

TRENCH NEPHRITIS.

TRENCH NEPHRITIS, which was recently the subject of an illuminating discussion¹ at a meeting of the Sections of Medicine and of Pharmacology and Therapeutics of the Royal Society of Medicine, has lately been described in a preliminary note² by Sir John Rose Bradford, who has had considerable experience of it in Flanders. He finds that but few cases of nephritis occurred among our troops until March and April, 1915; but in those two months far more cases were admitted to hospital than the total admissions for the whole period of the war up to that date. Further, in March and April typical renal dropsy, previously absent, was a marked feature of the cases. Trench nephritis continued to increase absolutely (and probably also relatively) during the summer of 1915; Sir John has clinically seen some hundreds of cases, and has had the opportunity to study the special case sheets of 1,455 cases under treatment at various periods since the outbreak in all the base hospitals of the Expeditionary Force in France. Early in the disease two symptoms are especially prominent—namely, dyspnoea and oedema. Casts were absent from the urine in over a third of the cases. The greater part of the paper is based on a series of 571 cases in which casts were present (usually both hyaline and granular), while occasionally blood casts were found. In one group of patients smoky or blood-stained urine was passed early in the disease, and fever was noted, much as may be seen in the infective nephritis of bacterial origin seen in civil practice. When dropsy was present the urine was much diminished in amount, and might indeed be suppressed for periods of twelve or twenty-four hours. Only three fatal cases have come under his own observation. In one a chronic Bright's disease had been present, in the other two congenital defects of the kidney were found, and in all death was due to uraemia. It is remarked that the facies typical of acute renal disease was of exceptional occurrence, and that the dropsy was never excessive in amount. The albuminuria was considerable in the acute stages, and was found to be much more persistent than the dropsy; uraemic symptoms were common, particularly an ammoniacal odour, apathy, drowsiness, headache, nausea, and occasionally vomiting. Epileptiform seizures of a considerable degree of severity, and increased arterial blood pressure, the latter often accompanied by severe headache, were by no means rare. In a few cases the characteristic dyspnoea was accompanied by the physical signs of pulmonary oedema. Other uraemic symptoms, such as twitchings, cramps, and skin eruptions, were not noted in this series of cases. Bronchitis occurred in some 30 per cent. of a series of 278 soldiers with trench nephritis; in those instances in which they were looked for, changes in the fundus oculi were absent, so far as the acute cases were concerned. Men of all ages and all branches of the service were attacked, but the disease occurred only in the British troops of the Expeditionary Force, and not amongst the Indian troops—among whom, in fact, but three cases were reported. Sir John sums up his account by saying that trench nephritis may be described as a clinical entity, characterized by the follow-

ing five features: The rapid subsidence of a well-marked renal dropsy, the frequent presence of bronchitis and dyspnoea, the severity and suddenness of onset of uraemic manifestations such as epileptiform seizures, the rarity with which inflammatory complications occur, and the extraordinarily low mortality of only 3 or 4 per thousand cases. He is inclined to believe that this form of acute nephritis is due to some infecting agent, which causes in the first place some illness, such as bronchitis, a severe cold, or diarrhoea. On the other hand, he remarks that bronchitis was common among the Indian troops, who yet escaped the acute nephritis. It may be added that in the discussion held by the Royal Society of Medicine referred to above, Dr. Abercrombie stated that he had been led by his large experience of the disease to assume that it was infective in origin and epidemic in distribution. The infecting agent, presumably a microbe, remains unknown.

BATHS EXTENSION AT BATH.

ALTHOUGH retrenchment is the order of the day, the city of Bath is engaging in fresh enterprise and cultivating its natural advantages to the utmost. Its apologia for so doing is the eight or nine thousand wounded or sick men who have already received free treatment at its springs. This influx, and the anticipation that the popularity of German and Austrian spas among British people will not be regained, has justified a new extension of the bathing establishment. The new "block" of baths, which was opened by Viscount French on February 23rd, consists of some fifty separate apartments arranged along either side of a corridor 200 ft. long. The accommodation provided here is chiefly for deep baths, in which the patient can be almost entirely immersed, while an undercurrent douche is applied to affected joints and muscles. There are also facilities for obtaining radiant heat and light baths, various modifications of the douche and douche-massage, and the Plombières treatment, which last is stated to have proved beneficial for men returning from the Eastern theatres of war suffering from the after-effects of malaria or dysentery. There is a room for mechanotherapy, and, reached by subterranean passages, a large swimming bath of the mineral water suitably cooled. With its floor of vitreous tiles, walls of glass mosaic, and bath linings of glazed fire-clay, the new building looks both pleasing and sanitary. Lord French, whose speeches had a soldierly brevity, made the acknowledgement that although scientific resources were being applied on an unheard-of scale in every branch of military activity, he had never seen, in flying school, or munition factory, or anywhere else, such a remarkable example of modern efficiency and adaptability as in the measures taken for the care and treatment of the wounded. With Lord French was Surgeon-General Russell, who suggested that it required no great stretch of imagination to suppose that the Romans took advantage of the waters of Bath for their wounded soldiers, in just the same manner as with the British wounded to-day. The civic luncheon at the Guildhall was made noteworthy by speeches from representatives of the medical services overseas. Surgeon-General G. C. Jones, Canadian Army Medical Corps, said that Canada had provided ten thousand beds in France and elsewhere; but although the hospitals were staffed and maintained by Canadians, they were for the wounded and sick from all parts of the empire, and imperial bonds were being formed in the military hospitals which would never afterwards be severed. Surgeon-General W. D. C. Williams, C.B., Australian Army Medical Corps, said that in Australia more motor ambulances were given at the beginning of the war than they knew what to do with, and these were readily offered to other imperial units requiring them. The medical profession in Australia, like the consultants, professors, and general practitioners, had given up everything to serve the empire. Lieutenant-Colonel P. G. Stock, D.M.S., South African Medical Corps, gave some reminiscences of the South-West African

¹ BRITISH MEDICAL JOURNAL, 1916, i, 278.

² Quarterly Journal of Medicine, Oxford, 1916, ix, 125.

campaign, and said that the bountiful waters of Bath gave an additional vividness to the recollection of how in that campaign the water had to be carried a thousand miles, with only one pint a day allowance for each man.

CHOLESTEROL AS A CAUSE OF ATHEROMA.

IGNATOVSKI found in 1908 that rabbits fed on animal food, particularly milk and eggs, developed arterial atheroma, cirrhosis of the liver, and enlargement of the suprarenal glands. These experiments have been followed up by Stuckey and others, and in 1913 Wesselkin came to the conclusion that the atheroma produced was due to the cholesterol contained in the eggs and milk. Dr. C. H. Bailey has repeated and extended¹ these observations. He finds that in rabbits a diet rich in cholesterol produces abundant deposits of anisotropic (or doubly refracting) fat in various organs and tissues. Prominent among these lesions is an atheroma of the aorta and pulmonary branches similar to that seen in human beings. In the liver these deposits produce cirrhosis, in the kidneys a proliferation of the interstitial tissue, mainly about the medulla. It is clear that the rabbit is unable to cope with large doses of cholesterol; if there is too much of this substance in its food, the animal becomes atheromatous. How far cholesterol can be regarded as the precipitating cause of atheroma or other forms of arterial sclerosis in human beings is a question of no little interest. It has been attacked by several writers, but their conclusions at the present time must be largely theoretical, as Dr. Bailey points out, for want of any adequate experimental basis.

THE LATE SIR WILLIAM TURNER.

THE funeral of Sir William Turner, on February 18th, was preceded by a service in St. John's Episcopal Church, of which he had been a member. It was attended by, among others, the Lord Provost, the magistrates and corporation of Edinburgh, the commander-in-chief in Scotland (representing Lord Kitchener), and by representatives of the University Court, the Senatus Academicus, the General Council, the Students' Representative Council, and the University Union of the Universities of St. Andrews, Glasgow, Aberdeen, Oxford, Leeds, and Bristol; of the Royal Colleges of Physicians and Surgeons of Edinburgh; of the Faculty of Advocates; of the British Association; of the Royal Societies of London and Edinburgh; of the Royal Infirmary, the School of Medicine for Women, and the Royal Medical Society. Sir William Turner has bequeathed the bust of himself to the University Court, with the request that it may be placed near the bust of his old master, Professor John Goodsir, in the anatomical museum of the university, in the planning of which and in the acquisition of specimens for which he took an active part as professor of anatomy. At the meeting of the University Court on February 24th a letter was read from the Secretary for Scotland, expressing his regret at the death of Sir William Turner and his sense of the loss the university had sustained. On the motion of the court the chairman adopted a minute, which concluded in the following terms: "The University Court, in placing upon record their sense of personal and corporate loss, desire also to express their conviction that the university will long cherish the memory of the unceasing and self-sacrificing labour which the late Principal devoted for so many years to its service." Sir James A. Russell (Edinburgh) writes: "I miss the names of the late John Halliday Scott, M.D., 1877, Professor of Anatomy at Otago (N.Z.), and of the late Alfred Harry Young, who succeeded the late Morrison Watson as Professor of Anatomy at Manchester, from the list of Sir William Turner's former assistants who became professors of anatomy which is given in your obituary notice. Professor Young served

about a quarter of a century; and Professor Scott, who died more recently, must have held office longer."

R.A.M.C. COMFORTS FUND.

At the beginning of October, 1914, a central committee of ladies was formed, composed of wives of Surgeon-Generals of the Army Medical Service, with Lady Sloggett, wife of the Director-General of the British Forces in France, as president, and Mrs. C. K. Morgan as secretary and manager. Its object was to collect, pack, and forward comforts to the various medical units in France. During 1915 this work was enlarged, and bales of comforts were sent to Gallipoli, and latterly to Salonika. Since the spring of 1915 parcels have been forwarded weekly to R.A.M.C. men who were prisoners of war in Germany, either directly by the comforts fund or by ladies who kindly "adopted" a man for a given period. Altogether 2,040 bales have been sent out from the Royal Army Medical College, London, where packing rooms were placed at the disposal of the committee. Of this number, 607 bales, each weighing 11 lb., have been sent to prisoners of war in Germany, and 1,433 bales, averaging 50 lb. in weight, have been forwarded overseas. From the list of garments dispatched it appears that shirts, socks, pants, and vests are those most in request; but cardigans, scarves, handkerchiefs, mittens, and towels have also been sent, as well as complete suits, greatcoats, caps, and boots to prisoners. From the numerous acknowledgements both from prisoners of war and from the officers commanding the various medical units on active service, the ladies feel that their efforts have been greatly appreciated by those they have endeavoured to help. The committee has been greatly assisted by various ladies of the corps who have established "dépôts" in Scotland, Ireland, and different parts of England for the collection of comforts. The amount of money received to the end of December, 1915, was £2,152 5s. 11d. The fund has been most generously supported by the various Royal Army Medical Corps Institutes, both at home and abroad. The committee wish to thank most heartily all those who have so generously helped in the past by donations, both in money and kind, and hope for a continuance of their support. Parcels of comforts should be sent to the secretary, Mrs. C. K. Morgan, "R.A.M.C. Comforts," Royal Army Medical College, Grosvenor Road, London, S.W., and cheques to the treasurer, Lieutenant-Colonel F. W. H. Davie Harris, 124, Victoria Street, S.W.

THE RISE IN THE PRICE OF PETROL.

FURTHER representations have been made to the Government in connexion with the price and supply of petrol to medical practitioners, and the Medical Secretary has received from the Commercial Department of the Board of Trade a letter stating that the matter is engaging the earnest attention of that department in conjunction with the Ministry of Munitions, and that it is hoped that arrangements will shortly be made whereby the difficulties which have recently been experienced will be as far as possible removed.

THE lectures during this session before the Royal College of Physicians of London will be given as follows: The Milroy lectures by Dr. S. G. Moore on infant mortality on March 9th, 14th, and 16th, the Lumleian lectures by Dr. F. E. Batten on polio-encephalo-myelitis on March 30th, April 4th and 6th, and the Oliver-Sharpey lectures by Dr. M. S. Pembrey on the development and regulation of temperature on April 11th and 13th.

AMONG the fifteen candidates selected by the Council for election into the Royal Society are Dr. J. A. MacWilliam, Professor of Physiology in the University of Aberdeen,

¹ *Journ. Exper. Med.*, New York, 1916, xxiii, 69.

and Sir Leonard Rogers, I.M.S., Professor of Pathology, Medical College, Calcutta. The other candidates include: Dr. D'Arcy W. Thompson, Professor of Natural History, University College, Dundee; Mr. H. H. W. Pearson, Professor of Botany in the South African College, Capetown; and Mr. C. Shearer, Lecturer on Experimental Morphology in the University of Cambridge.

Medical Notes in Parliament.

Central Medical War Committee.

In the official reports for February 29th the following questions and answers with reference to the Central Medical War Committee appear:

Mr. King asked: By what authority is the Central Medical War Committee compelling all single medical men of military age, under threat of conscription, to enrol themselves as ready to enter the Royal Army Medical Corps and to place their services at the disposal of this Committee, acting under the direction of the War Office?

Mr. Tennant: The Committee referred to is taking no such action as is alleged in the question. It has circularized medical men in England and Wales, explaining and emphasizing the need of more doctors for the R.A.M.C., and it has brought to their notice an enrolment scheme under which any man below 45 years of age who is willing to take a commission (if offered him) in the R.A.M.C. can secure that his application will be taken up by the War Office at the most suitable time, regard being had both to his particular circumstances and to the medical needs of the civil population in the area where he practises. In all these activities the Committee has been giving very valuable assistance to the War Office, and has been working in intimate relations with the various Government departments concerned.

Mr. King asked the Under Secretary of State for War whether the Central Medical War Committee, whose members are appointed, elected, or co-opted by the British Medical Association, is regarded as truly representative of the whole medical profession; whether he is aware that there are numbers of medical men who are not members of that Association; and whether the doctors who are needed to attend to the civil population are receiving by this arrangement adequate consideration.

Mr. Tennant referred to the answer he gave to a similar question by Mr. Shirley Benn on January 12th (see *BRITISH MEDICAL JOURNAL*, January 22nd, 1916, p. 140), and continued: I need only add to-day that since that date the Committee has been still further strengthened, and that the civilian aspects of the whole matter, to which the hon. member refers in the concluding paragraph of his question, are amongst the main preoccupations of the Committee working in conjunction with the Government departments involved.

Mr. King asked the Under Secretary of State for War whether, in view of the failure of the Army Medical Department to utilize effectively the medical services which have been freely offered to the army, it is the present policy of the Government to permit the Central Medical War Committee to portion out the supply of medical aid to the industrial community, including munition workers, upon whose energy we are so dependent; and whether, in order to secure the health of the civilian population, the medical profession will in future be classed, like clergymen, as a reserved occupation.

Mr. Tennant: No, sir, I am not aware of any such failure. Such a word seems quite out of place in commenting on the work of the Royal Army Medical Corps. The Committee referred to has collected valuable information as to the existing and prospective provision of medical services for the industrial community, and is endeavouring to assist various members of the profession in bringing about such rearrangements and co-operation as may facilitate the most effective distribution of those services where needed. Information as to the present condition of medical provision in England does not afford any grounds for resorting to the sweeping measures suggested in the concluding paragraph of the hon. member's question.

War.

Employment of Medical Staffs.—In reply to Mr. Lynch, Mr. Tennant said that civilian medical officers were employed to a very small extent in Territorial general

hospitals, which were staffed by officers of the Territorial Force. The number mobilized varied with the number of patients in the wards. The number of medical officers in the base hospitals in France could not be reduced, as the military authorities considered that the number now so employed had reached an irreducible minimum. Mr. Lynch also asked whether a certain number of medical officers were attached to each division and their services limited exclusively to it; or whether, when a single division was engaged in a struggle so protracted that its medical officers and staff were exhausted, medical officers from a neighbouring division not engaged could be drafted into the exhausted division. Mr. Tennant said that this course was followed. It was the duty of the higher military authorities to distribute the medical officers under their command so as to meet the various exigencies which might arise. The watertight compartment arrangement was obviously undesirable. He added, in reply to another question, that he had no knowledge of an instance in which some medical officers were employed for fifty-two hours at a stretch, whilst those of another division were unemployed. Movable hospitals or a closely connected series of hospitals within a short distance of the firing line had been in use for many months.

Army Medical Advisory Board.—In reply to Mr. Lynch, Mr. Tennant stated that the unofficial members of the Advisory Board for Army Medical Services were Professor Kenwood, Sir John Rose Bradford, Professor Leonard Hill, Sir Anthony Bowlby, and Sir Charles Cameron. Sir Anthony Bowlby and Sir John Rose Bradford were on the Board as representing surgical and medical knowledge respectively, and not as representatives of what Mr. Lynch had called "civilian interests."

Theological and Medical Students.—Mr. Robinson asked, on February 29th, whether the exemption of students preparing for the Roman Catholic priesthood would be extended to other theological students, and Mr. Snowden whether the exemption would be given to medical students. Mr. Tennant said that instructions were being prepared under which theological students of all religious denominations would be treated alike. No alteration had been made in the decisions already announced in reference to medical students. The regulations had been framed upon the same lines as those for theological students; if there were any distinction, perhaps the treatment of the medical student was the more generous.

Blinded Soldiers and Sailors.—Mr. Tennant has given the following statistics as to the number of officers, non-commissioned officers, and men discharged from the army for blindness, which he had obtained from Mr. C. Arthur Pearson, chairman of the Blinded Soldiers' and Sailors' Care Committee, who, as Mr. Tennant said, has done admirable work. The total number of non-commissioned officers and men was 156 (English 122, Irish 16, Scottish 15, Welsh 3). The number of British officers was 9 (English 6, Irish 2, Welsh 1). Dr. Macnamara stated that 5 naval officers and men had lost their sight in the war entirely, and, as it was believed, permanently; 2 had been discharged, the one a sapper, R.N.D., with a life pension of 25s. a week, and the other a petty officer, second class, coastguard, with a life pension of 27s. a week; 1 midshipman, 1 ordinary seaman, and 1 boy were still under naval care. One private, Royal Fleet Reserve, had lost the sight of one eye, and that of the other was so affected that the man was practically blind. He was receiving a pension of 26s. 2d. a week, and his case would be reconsidered in six months. The question whether men who had been blinded would be able to earn anything could only be settled when their aptitude for acquiring knowledge as blind men had been gauged, and this would be a matter for the Statutory Committee of the Royal Patriotic Fund Corporation, on whom the responsibility for finding employment for disabled sailors and soldiers had been placed by Parliament.

Nervous Shock.—In reply to Mr. King, the Under Secretary of State for the Home Department (Mr. Brace) stated, on February 23rd, that no further facilities were being offered through the Board of Control for the accommodation and treatment of nerve-shaken soldiers, as no further accommodation could be spared. At the request of the War Office, the completion of the new Hampshire Asylum at Park Prewett was being expedited with a view to its being equipped and staffed by the military authorities as a

temporary war hospital. The Board of Control did not exercise supervision over any military hospitals. Visits that it had made for many years to a special section of Netley Hospital, and more recently to temporarily adapted hospitals for nerve shaken soldiers, including the Maudsley Hospital at Denmark Hill, had been made at the request of the military authorities. The responsibility for the treatment of the soldiers in question rested entirely with the military authorities, and not with any asylum authorities. On February 24th, in reply to Mr. Butcher, who asked whether a special hospital had been established for these cases, Mr. Tennant said that they were being treated in the neurological section of the Territorial General Hospitals, in the Springfield War Hospital, Wandsworth, and the Red Cross Military Hospital, Maghull, near Liverpool. The present arrangements were satisfactory and it was not proposed to alter them.

Hospital Beds in London.—In reply to a question on February 29th, Mr. Tennant stated that on February 12th, 1916, there were in military hospitals in London 2,437 wounded soldiers; in auxiliary hospitals 1,267; and in civil hospitals 578. There were 5,346 vacant beds.

Standard of Vision.—Mr. Tennant informed Mr. Duncan Miller, on February 29th, that the vision of applicants for commissions in the army must not be below $\frac{1}{2}$ without glasses, and after correction with glasses it must be normal in the better eye and $\frac{1}{3}$ in the other. For candidates in the Special Reserve of Officers the standard required is as just stated, except that vision without glasses in each eye must not be below $\frac{3}{8}$. There is no special standard required for active service as distinct from home service.

Military Service Act.—The following are notes of replies to various questions in the House of Commons on February 29th:

Mr. Tennant said that it was not at present proposed to follow the example of enemy countries by extending the age for enlistment to 45, but there was power to extend the age limit to the extent which might be necessary. A single man of military age discharged from the Territorial Force on grounds of ill health, or on completion of his period of service, was exempted from the provisions of the Military Service Act, 1916. The production of a certificate issued to a man by a doctor employed by the military authorities, showing that the man had been rejected, was sufficient to relieve the man from liability to military service under the Act, provided the authorities were satisfied that the certificate was really issued to the man in question and was issued since August 14th, 1915. The question of reserving plumbers from recruiting owing to the importance of their work to the public health, was under consideration. It was expedient that a man should be vaccinated or revaccinated, but if he did not sign an undertaking to be vaccinated, no pressure was to be brought to bear upon him if he had conscientious objections. The present arrangements were provisional for the period of the war only. Dr. Addison (Parliamentary Secretary to the Munitions Department) said that a certificate rightfully held by a workman in a controlled establishment, with a war badge, on March 1st would be valid as a certificate of exemption under the Military Service Act. The wife of a man married since November 2nd and now called up would, Mr. Forster stated, be entitled to receive separation allowances. Mr. Long stated that twenty-five appeal tribunals, representing counties or parts of counties, had been set up, and the remainder, together with the central tribunal, would, he hoped, very shortly be constituted.

Pensions for Discharged Soldiers.—In the House of Lords on February 29th Viscount Peel raised the question of pensions and allowances to soldiers discharged from the army on account of wounds and diseases contracted or developed on service, and urged that the stipulation that in order to entitle a man to a pension his disablement must be due wholly to the war was too severe. Lord Beresford said that men discharged from the army were left for weeks at what was for them the most critical period without pensions; he suggested that pay and allowances should be continued until the pension was fixed, that the gratuity of £2 should be given to the man immediately on discharge; that back pay should be paid on discharge, and that pensions should be equalized. The Paymaster-General (Lord Newton) said that the Chelsea Commissioners who administered the pay pension warrant were uniformly sympathetic to the disabled soldier, but an enormous amount of work had been thrown upon them, and unfortunately a large number of the men made no effort to obtain employment. There were numerous instances of pensions having been awarded

to men who had hardly performed any military service. With regard to the allegation that the War Office did not recognize tuberculosis and frost bite as being due to military service, he said that last January 87 cases of tuberculosis contracted in France were dealt with at Chelsea and pensions awarded in '79, the remaining 8 being still under consideration. The allegation with regard to frost-bite was founded on a pure fiction related in a police court. He admitted that there were cases of hardship, and it was to deal with such that the Statutory Committee had been created. Where military service had brought to light a latent or constitutional disability the practice was to give a small pension under an earlier warrant. The continued conflict which went on was due to the fact that vast numbers of physically unfit men had been recruited, but such a condition of things was inseparable from the voluntary system, for the Government had to choose from among the men who offered. In one battalion no fewer than sixty men had been invalided who had practically had no military service. The total amount paid in pensions for disabilities incurred during the war was £1,500,000 a year, and if the war lasted to March 31st, 1917, this amount would rise to £7,500,000. If all men discharged received pensions the amounts would be £2,250,000 and £11,360,000 respectively. The Marquess of Lansdowne said that the fact could not be disguised that in a great many cases medical examinations had been conducted with culpable negligence and laxity, and he was not prepared to say that when a man had been formally accepted in the army by responsible officials of the State, he could afterwards be mulcted because those officials failed to perform their duty with the amount of care reasonably to be expected from them. In reply to an inquiry, the Marquess of Crewe said that the Statutory Committee had already appointed certain subcommittees, which were preparing a model scheme. The statutory subcommittees would be appointed within a few days. At present the work of looking after disabled men was being continued by the voluntary organizations, which were doing it well, and the Statutory Committee would maintain permanent relations with them. From June, 1915, to the middle of January, 1916, the names of 23,000 men were received by the Board of Trade from the War Office and the Admiralty; of these 13,000 applied to the Labour Exchanges for help in finding employment; 5,400 found places through the exchanges; 1,439 were still on the register, but close on 6,000 had cancelled their applications, no doubt in many cases because they found they were not fit to take up any kind of serious employment, and in others because they had found work otherwise.

Midwives (Scotland) Act.—In reply to a question by Mr. Watt, who asked whether the Central Midwives Board (Scotland) had power to spend money with the right to tax municipalities and other local authorities for any deficit between its income and expenditure, Mr. McKinnon Wood referred to Section 13 of the Act, which provides that if the annual official statement shows a balance against the Board and the accounts are approved by the Privy Council, the Board may apportion such balance between the local supervising authorities in proportion to the populations of their districts as ascertained at the last preceding census. Mr. Wood said that, judging from the experience of the working of the English Act, there appeared no likelihood of any immediate or substantial claim upon local authorities.

On January 24th the President of the United States received a deputation consisting of the President of the American Medical Association, Dr. W. L. Rodman, and the presidents of fourteen State medical societies, to present a formal request that in any new legislation for the defence of the country the medical departments of the army should be treated with equity, and be increased in proper proportion to the military needs as finally determined. It was therefore urged that a trained corps on a scale sufficient for peace needs and for any other eventualities should be created. Urgent messages were submitted from the presidents of the medical societies of all the other States of the Union not represented in the deputation, supporting its action and calling for medical preparedness. The President promised to consider the matter.

THE WAR.

A GIANT DISINFECTOR.

(From a Correspondent in Northern France.)

In a war when everything is on so large a scale one's perception perhaps gets a little blunted. Otherwise I suppose I should have already mentioned a super-dreadnought in the way of mobile disinfectors that is at work out here. It is some months since I first saw a specimen, but only recently that I realized its strong points. These are its durability, the effectiveness with which it does its work, and the amount of this that it is capable of completing within a relatively short time.

In its general appearance it recalls a brewer's dray carrying two extra large barrels. The dray is a flat-topped motor lorry whose chassis is supplied not with a petrol, but a steam-driven engine. The two hogsheads or barrels are the bodies of twin disinfectors built upon the Thresh principle and capable of being used either separately or simultaneously. They are connected by piping with the engine of the lorry, and all that is necessary to set them in action is to cut off the steam from the driving cylinders, and turn it into the jackets of the disinfecting chambers. Consequently the disinfector is ready for action the moment a journey has been completed, and of course can be left standing, but still in use, for an unlimited time, at any place to which it has been brought. The chamber of each twin has a capacity of 60 cubic feet. The joint capacity is therefore nearly three times that of an ordinary mobile Thresh apparatus, such as has long been more or less familiar in sanitary work in Great Britain.

The construction, however, of this giant—which is capable of dealing with the whole of the blankets of a battalion within a limit of two ordinary working days—was, I understand, originally due less to a desire for larger Thresh disinfectors than those at first in use than for a type which would stand the wear and tear on active service more satisfactorily. The original pattern was attached to a horse-driven vehicle with iron shod wheels, and this, when driven over roads so rough as are many of those in Northern France and Flanders, shook so much that pipe-joints and steam-tight doors soon became defective. The chassis on which the present machine is carried has, like all other lorries, twin back wheels with solid rubber tyres. The vibration, therefore, is reduced to a minimum provided the pace at which it is driven does not exceed ten or twelve miles an hour.

I understand that quite a large number of divisions are now supplied with disinfectors of this type.

INDICATIONS FOR AMPUTATION.

It appears from a recent address by Professor Albrecht¹ at a meeting of war surgeons that the Austrian army surgeons have been accused, not only by the lay public, but even by their civilian colleagues, of performing too many amputations. Professor Albrecht indignantly denied these accusations. That surgeons in the interior did not find it necessary to amputate was obviously due to the fact that patients in need of amputation either died at the front or were operated on there. He admitted, however, that the decision for or against amputation was often one of the most difficult problems of war surgery; he had never sacrificed a limb needlessly, but he had occasionally regretted that he had not amputated, or had deferred the operation too long. During eight weeks he had treated about 2,500 patients, most of whose wounds were severe, and of the 240 operations 18, or 8 per cent., were amputations.

Gangrene due to Tourniquets and Bandages.

From time to time he had seen cases of gangrene provoked by the constriction of bandages. Rubber tubing tied round a limb to arrest haemorrhage, uncontrollable by other means, was the commonest cause. The surgeon who had applied such a tourniquet should not let the patient be transferred elsewhere unless it were absolutely certain that he would be under medical care again within three hours. The patient who had perforce to be transferred

under these conditions should be liberally labelled "rubber tourniquet." Another fatal mistake was the changing of the outer dressings only; no dressing should be applied until the wound had been freely exposed. How fatal the neglect of this precaution might be was illustrated by the following case:

Among a convoy of severely wounded was a patient whose appearance was miserable. He was exceedingly restless, and complained of excruciating pain. A projectile had passed through the upper third of the right humerus, and around the arm and shoulder a spica bandage had been secured. The arm was gangrenous, and there was oedema encroaching on the right side of the neck. After the spica had been removed a second, circular bandage was found to have been applied to the upper third of the arm. Under this bandage again a rubber tourniquet was found, encircling the arm just below the shoulder. This tourniquet had been in place forty hours. The humerus was enucleated, but the patient died next day.

Occasionally plaster-of-Paris bandages were secured too firmly, and not watched closely enough. It was a mistake ever to let a patient be moved elsewhere directly after a plaster-of-Paris dressing had been applied. The case should be kept under observation for the first forty-eight hours by the surgeon who had applied the dressing. The neglect of this precaution might provoke gangrene, and in November, 1914, Professor Albrecht had to amputate the arm of a patient, the diaphysis of whose humerus had been fractured by a rifle bullet. A plaster-of-Paris dressing had been applied, and when he reached hospital gangrene of the forearm had developed. Another source of danger were starch bandages (Organtin-Stärkebinde) which shrank considerably on drying. Unless the surgeon was careful to interpose plenty of cotton-wool between the margins of this bandage and the limb, gangrene was liable to supervene.

Gangrene due to Wounds of Blood Vessels.

At the beginning of the campaign he had hoped to practice the latest technique of blood-vessel suture, but in the course of a whole year he had not seen a single case of wound of an artery suitable for this delicate operation. Either the limb was gangrenous or it was the seat of such severe phlegmonous inflammation that this operation was out of the question. The surgeons who attended the wounded at the outset had seldom the necessary time, experience, or instruments.

Gangrene due to Infection.

Fractures and wounds of joints frequently necessitated amputation owing to infection. Among a draft of over 100 severely wounded, which reached Professor Albrecht's hospital in November, 1914, were three whose appearance suggested the final stage of pernicious anaemia. They had been wounded only thirty to forty-eight hours earlier, and none of them had lost much blood. Yet they were very febrile, and lay groaning motionless in bed, with sunken eyes, small rapid pulse, and dry tongue. All three had been wounded by projectiles, which had fractured one or more bones of the lower limbs. Two of them were too debilitated to stand an amputation, and died next day. The third, a powerful young man, was operated on at once. He was febrile a few days after the amputation, but ultimately recovered. Professor Albrecht's suspicion that these patients were infected by haemolytic micro-organisms was confirmed by subsequent observations on similar cases in which a bacteriological examination was made. In one such case the clinical picture was that of the last stage of cholera, although the patient was not suffering from this disease, but from infection with a streptococcus and *Bacillus proteus*. As a rule, infection due to the colon and *proteus* bacilli was less serious than with the Fraenkel-Welch bacillus, and that of malignant oedema. Amputation had been performed only in the most severe cases of gas gangrene. It had been avoided in many cases by the free use of long incisions carried far into the apparently healthy tissue. They were made in the course of the wound, and were carried through the deep fascia to the muscles, so that no crop of anaerobic germs could escape free ventilation. When the general condition was very bad, and the gas gangrene spreading rapidly, amputation, well above the level of the gangrene, was inevitable. From his experience of several cases, he repudiated v. Oettingen's dictum that infection with the *Bacillus pyocyaneus* was in itself an indication for amputation.

¹ *Wien. med. Woch.*, November 6th, 1915.

Septic Wounds of Joints.

The conservative treatment of a suppurating joint required the greatest skill and experience. Provided the patient's general appearance and appetite were good, the tongue was moist, and the action of the heart satisfactory, fever did not of itself warrant amputation. But if the pulse became more and more rapid, weak and irregular, no time should be lost. Special importance was to be attached to irregularity of the pulse as a warning not to delay operating. The problems arising in connexion with amputations required such skill and experience that the Austrian army would do well to follow the example of the German army and provide a consulting surgeon for every army corps.

PROPORTION OF RECOVERIES AMONG THE WOUNDED.

A RECENTLY published report embodying the statistics of a large *hôpital de triage* (sorting hospital) at Bordeaux gives some interesting figures. The hospital in question received in twelve months 64,385 wounded; of these 38,902 (60 per cent.) were able to rejoin their regiments after treatment. To this number must be added those who rejoined their regiments after a furlough for convalescence, 18 per cent. The remainder comprises two categories of men, namely, those who are set back temporarily and are subject to periodical re-examination, and those who are discharged altogether. The former of these two categories accounts for 15.45 per cent. and the latter, the discharged men, to only 6.55 per cent. of the total. It follows that of the wounded who reached this hospital only just over 6 in a 100 had been rendered permanently unfit for military service.

The German authorities recently claimed that during the first year of war the monthly average percentage of their wounded who were discharged "fit for service" was 89.5, and "discharged or sent on leave" 8.8 per cent.; the deaths were 1.7 per cent. The results of treatment in military hospitals in Great Britain and Ireland during the first year of the war were as follows—died 0.86 per cent., permanently unfit 4.14 per cent., discharged to duty, on furlough or sent to convalescent homes 95 per cent. Such statistics are interesting, but as has been pointed out on previous occasions they do not indicate the ratio of men who have died of wounds to those who have recovered more or less completely. They throw light only on the results in men who reach a certain class of hospitals.

CASUALTIES IN THE MEDICAL SERVICES.**ARMY.***Killed in Action.*

LIEUTENANT FRANCIS SIDNEY MITCHELL, R.A.M.C., was killed in France on February 15th, aged 26. He was the youngest son of George Mitchell of Ardlui, county Dublin, and was educated at Trinity College, Dublin, where he took the M.B., B.Ch., and B.A.O. in 1915. He had only recently taken a temporary commission in the R.A.M.C., and was attached to the 9th Battalion of the Sussex Regiment when killed.

Lieutenant Bernard Bradley Gough, R.A.M.C., was killed in France on February 16th. He was educated at Guy's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1897, after which he acted as clinical assistant in the medical wards at Guy's, and as house-surgeon of the General Infirmary, Burton-on-Trent. He then went into practice at Compton Martin in Somersetshire, near Bristol, where he was medical officer and public vaccinator of the Harptree district of the Clutton Union. He was attached to the 8th Battalion of the South Staffordshire Regiment.

Died on Service.

Captain John Dykes Wilson, Indian Medical Service, died at Tillicoultry on February 16th. He was educated at Edinburgh University, where he took the M.A. and also the M.B. and Ch.B. in 1909, afterwards studying at Munich, Vienna, and Breslau. After qualifying he acted as house-physician of the Sunderland Royal Infirmary, and as assistant medical officer at the Royal Infirmary, Sheffield. He entered the I.M.S. as lieutenant on July 27th, 1915, and became captain on July 27th, 1915.

Captain Alfred Gwilym Jones, R.A.M.C., died of pneumonia at Rawal Pindi on January 27th. He was educated at Guy's Hospital, and took the M.R.C.S., the L.R.C.P. London, and the M.B. and B.S. London in 1905. After qualifying he filled the posts of house-surgeon, clinical assistant, and out-patient officer at the London Hospital, and then entered the R.A.M.C. as lieutenant on July 31st, 1909, becoming captain on January 31st, 1913.

Captain Peterswald Pattison, R.A.M.C., died in Edinburgh on February 22nd, and was laid to rest in Warriston Cemetery, Edinburgh, on February 25th. Though known intimately to only a very few of his profession, he was unhesitatingly regarded by them as one of the choicest spirits they had ever met. "Pete," as he was always affectionately called by his intimates, graduated M.B., Ch.B. in 1901 at the University of Edinburgh, and though his own tastes lay in the direction of the navy, he relinquished this ideal, deferring to the wishes of his invalid father. Hospital residencies at Stirling and Chester, and several voyages as ship surgeon, preceded his starting practice at Colinton. A character such as his, however, was little suited for the rough-and-tumble of a practitioner's work, and accordingly, after taking the diploma of D.P.H. in 1910, he became school medical officer in Fife, acting also as Assistant M.O.H. for the county. This position he resigned on receiving a commission as temporary lieutenant R.A.M.C. on November 21st, 1914, and he seemed at last to have found the real work suited to his cheery optimism. He was promoted to temporary captain on November 21st, 1915. In France he was attached to the K.O.Y.L.I., in the trenches doing splendid work, but after struggling for weeks against grave symptoms which had begun to appear, he was invalided home in July; his malady was found to be incurable, and he lingered for six months in a nursing home. His was a most lovable nature combined with a strong individuality. Reserved almost to shyness, to his intimates he revealed himself as a man of the staunchest character, with an almost exaggerated sense of duty, of unsurpassable kindness, and endowed with a quaint and whimsical humour. In health it was his to "labour smiling," and when there came "the day marked for sorrow," he was no less "strong to endure it."

Captain Archibald Thomson Campbell, R.A.M.C., died in Glasgow on February 22nd. He was educated at Glasgow, where he took the M.B. and C.M. in 1886, and was in practice in that city, where he was for some time anaesthetist to the Glasgow Dental Hospital. He took a commission as captain in the Home Hospital Reserve of the R.A.M.C. from August 16th, 1914.

Lieutenant Richard Gavin Brown, R.A.M.C., died at the 5th Southern General Hospital, Portsmouth, on February 14th. He was the only surviving son of Deputy Inspector-General R. Gavin Brown, R.N. He was educated at Aberdeen, where he took the M.B. and Ch.B. in 1903, afterwards serving as assistant medical officer, Lambeth Infirmary, and house-surgeon, Tynemouth Victoria Jubilee Infirmary. He then went into practice at Portsmouth, where he was assistant anaesthetist to the Royal Portsmouth Hospital. He took a temporary commission in the R.A.M.C. from March 29th, 1915, and had recently returned from service in the Gallipoli peninsula.

Wounded.

Captain H. B. Cunningham, R.A.M.C.(T.F.), France.
Captain W. M. Biden, R.A.M.C., Special Reserve, France.

Prisoners of War.

Major Priestley and Captain Vidal, R.A.M.C., released prisoners of war from Germany, reached England on February 23rd. Both were taken in August, 1914, in the retreat from Mons, and had been detained as prisoners ever since. Both had served in the epidemic of typhus among prisoners of various nationalities at the soldiers' prison camp at Wittenberg, in Saxony, where Major W. B. Fry and Captains A. A. Sutcliffe and S. Field, all of the R.A.M.C., contracted the disease and died last March and April.

Combatant Officer Killed.

Lieutenant J. Thorp Waite, whose death in action was noted last week under the head of "Deaths among sons of medical men," was himself a member of the medical profession. He was born in 1870 in Halifax,

where his father had long practised. He received his medical education at the University of Edinburgh, and took the Scottish triple qualification in 1896. After practising at home for some time, he joined the West African Medical Staff and served in Northern Nigeria, and later acted as ship surgeon. In 1899 he returned to England, married, and began to practise first in Yorkshire, and then in Pluckley, Kent. He joined the Territorial Force, and took a keen interest in stimulating recruiting for it. He received a commission as lieutenant (combatant) in the 5th Buffs on August 22nd, 1914, and was sent to India. Afterwards he went with the Expeditionary Force to the Persian Gulf, and was killed when serving with the machine gun section of his battalion. He leaves a widow and young son.

DEATHS AMONG SONS OF MEDICAL MEN.

Griffin, Innes Edward, Captain 14th Battalion, Oxford and Bucks Light Infantry, son of the late Dr. Innes Griffin, medical officer of health, Banbury, died of wounds on February 19th. He had just returned to the front after short leave home. His first commission as second lieutenant was dated August 8th, 1914; he was promoted to lieutenant on January 9th, 1915, and to captain last summer.

Hood, George Christie, Lance-Corporal 16th (Public Schools) Battalion, Middlesex Regiment, only son of T. A. F. Hood, M.B., of Ivybank, Blairgowrie, died at No. 33 Casualty Clearing Station, in France, on February 19th, of wounds received on February 15th, aged 21.

CORRECTION.—In the list of casualties published last week the name of Lieutenant John Gillis Butt was incorrectly printed Bute.

NOTES.

HONOURS.

ROYAL NAVY.

AMONG various honours announced by the Admiralty on February 24th, the Distinguished Service Cross was conferred upon Surgeon Alfred Robinson MacMullin, R.N., "for services on January 23rd, 1916, at Sereugeti, in East Africa, when he showed remarkable bravery in searching for and rescuing a severely wounded officer under heavy machine gun and rifle fire close to concealed enemy entrenchments."

FOREIGN ORDERS.

The *London Gazette* of February 24th announced the names of a number of officers to whom His Majesty had given permission to receive and wear certain French and Belgian orders conferred on them for services in the war. Among them were the following medical officers:

France.

Commander of the Legion of Honour.—Surgeon-General W. G. Macpherson, C.B., C.M.G., A.M.S., Surgeon-General T. P. Woodhouse, C.B., A.M.S., Colonel Sir W. B. Leishman, C.B., A.M.S.

Officer of the Legion of Honour.—Colonel C. H. Burtchall, C.M.G., A.M.S.

Chevalier of the Legion of Honour.—Major W. R. Battye, D.S.O., I.M.S., Major R. B. Black, Reserve of Officers, R.A.M.C., Major J. S. Pascoe, R.A.M.C., Major E. Ryan, D.S.O., R.A.M.C., Major J. W. West, R.A.M.C., Captain F. Casement, R.A.M.C., Captain D. M. McWhae, Australian A.M.C., Major J. Morley, R.A.M.C.(T.F.), Captain J. W. Craven, R.A.M.C.(T.F.).

The Croix de Guerre and the Médaille Militaire have been conferred upon a large number of British Warrant Officers, N.C.O.'s, and men, among whom were the following members of the medical services. All are R.A.M.C. unless otherwise stated:

Croix de Guerre.—Quartermaster-Sergeant R. E. Halford, Corporal E. Allen (T.F.), Driver J. C. Conyns (Australian A.M.C.), Private H. W. Strong (Australian A.M.C.), Bearer Beni (Indian Army Bearer Corps).

Médaille Militaire.—Second-class Assistant Surgeon G. C. Rehling (I.S.M.D.), Quartermaster-Sergeants G. Carroll (T.F.), H. W. Lee, and J. E. Newton, Staff Sergeants W. H. Mattison and J. Rouse, Sergeants W. Brooks (T.F.), and W. D. Gibb (T.F.), Corporal G. E. Thain, Driver E. Smith (R.F.A., formerly R.A.M.C.), and Private W. Adamson (T.F.).

Belgium.

Commander of the Order of Leopold.—Surgeon-General Sir A. T. Sloggett, K.C.B., A.M.S.

Officer of the Order of Leopold.—Colonel S. G. Moores, C.B., A.M.S.

Commander of the Order of the Crown.—Surgeon-General R. Porter, A.M.S.

Officer of the Order of the Crown.—Lieutenant-Colonel S. L. Cummins, C.M.G., R.A.M.C., Lieutenant-Colonel A. Chopping, C.M.G., R.A.M.C.

MEDICAL OFFICERS WANTED.

2nd London Sanitary Company R.A.M.C.(T.).

There are some vacancies for commissions in this company. Gentlemen with public health experience or holding the D.P.H. preferred. There is a prospect of active service abroad after a brief period of training. Apply, Captain F. G. Caley, O.C. 2nd London Sanitary Company, Duke of York's Head Quarters, Chelsea, S.W.

3rd City of London Field Ambulance, R.A.M.C.(T.F.).

Three or four medical officers (Imperial Service) are required for this ambulance, promotion to captain at the end of six months' service. Very economical mess. Field allowance, in addition to pay, is being drawn. Applications should be sent to the Commanding Officer, Beech Hill, Hadley Wood, Barnet.

South Wales Mounted Brigade.

There is a vacancy for a medical officer in the Mounted Field Ambulance and also in one of the Yeomanry regiments of the 2/1st South Wales Mounted Brigade. Applications should be sent to Lieutenant-Colonel Herbert Jones, S.M.O., Bulcamp, Blythburgh, Halesworth.

England and Wales.

It was announced a couple of months ago that a memorial fund was being raised to commemorate the devoted and faithful service at the Manchester Royal Infirmary of Sister French, who died last November. It is proposed to place a tablet in her old wards in S.I. Unit, and a small stained-glass window in the infirmary chapel. We have received a letter from Mr. G. A. Wright, consulting surgeon, and Mr. J. Howson Ray, surgeon to the Infirmary, in which they say: "We believe that many former students of the Manchester Royal Infirmary would like to join in this memorial, and we invite donations, which may be forwarded to the general superintendent and secretary, by whom all contributions will be gladly acknowledged."

At a meeting of the Manchester Board of Guardians last week it was decided to accept the proposal of the War Office, which had requested that a large part of the Withington Hospital should be devoted to the care of sick and wounded soldiers, the guardians continuing the administration of the place, as they already possess a trained staff. Arrangements are accordingly being made for the transfer of something like 1,200 of the present inmates to other institutions. The Booth Hall Infirmary will be vacated by the military authorities and is to be used for the housing of the sick children, while the two other institutions at Crumpsall will be utilized for other cases. It is expected that the new arrangements will provide accommodation for 2,000 sick and wounded soldiers, in place of 400, as at present.

CENTRAL COUNCIL FOR DISTRICT NURSING IN LONDON.

The Central Council for District Nursing in London, founded in 1914 as the result of a conference under the auspices of the Local Government Board, held its annual meeting on February 25th, when Sir William Collins presided. The annual report stated that the Ranyard Nurses and the associations affiliated to Queen Victoria's Jubilee Institute reported that there had been an unexpected decrease of work in certain areas, at least so far as ordinary acute cases were concerned; this was ascribed to the fact that people were better paid and better fed. The executive committee reported that at the next meeting a statement would be made as to the desirability of extending the Council's work beyond the area of the County of London, and that a subcommittee was now engaged in investigating the adequacy and efficiency of district nursing in various London boroughs. A proposal was approved to publish a directory and guide to district nursing whereby medical practitioners, hospital authorities, and others might readily ascertain where to apply for the services of a district nurse in any part of the metropolis. It was explained that the preparation of the scheme for the district nursing of measles, German measles, and whooping-cough, which the executive committee had been directed to draw up, had been delayed to some extent by the order of the Local Government Board for the compulsory notification of measles, which conferred upon any borough council the power to

provide, or contract with any person to provide, a temporary supply of medicine and medical assistance for the poorer inhabitants of the district. An arrangement whereby a borough council could contract with a district nursing association would be both economical and efficient. Not every case would need actual nursing, as distinct from advice and supervision, by a district nurse, and in making the selection of cases the M.O.H. would be assisted by the knowledge of the families and the local circumstances in the possession of the education and other local authorities. On the subject of medical attendance it is stated categorically that "the district nurse should under no circumstances assume any responsibility for medical treatment." It was her duty to advise the parents that a medical man should be called in. She should continue to urge the need for calling in the doctor, and in the meantime do her best for the patient. The memorandum prepared by the medical officer of the Local Government Board was quoted to the effect that, "without taking medical responsibility, the nurse can do much to prevent complications." Various suggestions were made as to the desirability of providing beforehand for medical attendance by means of provident dispensaries and the like. In the absence of all other provisions application might be made to a relieving officer, or resort might be had to a charitable fund, raised through the District Nursing Association, out of which the payment to medical men could be made. So far as admission to hospital was concerned, the nurse was only affected in that it was her duty to select the more urgent and necessitous cases for hospital treatment. In an appendix to the draft, suggestions were put forward for the modification of district nursing rules as an addendum to any existing rule barring the nursing of infectious cases. These ordain that the nurse shall carry out all instructions given by the medical attendant for the avoidance of risk of conveying infection to her other patients; in the absence of such instructions she shall comply with the rules of the committee of her association; she shall assist the sanitary authorities as far as possible in preventing the spread of the infection, and shall not visit a maternity case without the sanction of a medical practitioner. An addendum is also suggested to existing rules regarding the nursing of cases to which no practitioner has been called. This requires that the nurse shall urge the parent to call in a doctor, explaining, especially as regards children under 5, the serious dangers which may develop, and that in the event of continued neglect on the part of the parent, she shall report the case to the M.O.H., and also to her superintendent, and, pending their instructions, shall continue to urge the parent to obtain medical attention, at the same time doing her best for the patient by homely advice and household management. (The draft of the scheme is published by P. S. King and Co., Limited, price 2d.)

On the motion of Sir Arthur Downes an executive committee of twenty-five members were reappointed, the medical representatives being Dr. William Butler, Dr. Ronald Carter, Sir William Church, Sir Arthur Downes, Dr. C. J. Harrison, Dr. G. F. McCleary, Sir Shirley Murphy, Dr. B. A. Richmond, and Mr. E. B. Turner.

TUBERCULOSIS IN LONDON.

It was stated at the meeting of the London County Council on February 22nd that a model scheme for the formation of tuberculosis care committees, to form part of the organization of each tuberculosis dispensary, which was approved some eight months ago, would be considerably delayed owing to the increasing demands made on voluntary workers. The Council agreed to the formation of interim care committees, to include existing local dispensary care committees, the M.O.H. for the borough, the tuberculosis officer, local social workers, representatives of local hospitals, and other persons contemplated in the model scheme as originally put forward. The Public Health Committee stated that, owing to various causes, the scheme for the residential treatment of tuberculosis in London had not developed as rapidly as was anticipated. It seemed probable that, apart from the beds supplied by the Metropolitan Asylums Board, not more than 231 beds for children and 100 beds for adults would come into use during the current year. On this basis the estimated cost of residential treatment would be £16,800.

MEDICAL EDUCATION OF WOMEN IN WALES.

The first public meeting of a committee formed to promote the medical training of women in Wales was held at the University College of South Wales and Monmouthshire last week. Mr. D. Lleufer Thomas, who was in the chair, said that head mistresses stated that girls likely to be successful in a medical career were prevented from embarking on it by the heavy expenses and the long period of training. There were very few medical scholarships for women, and the object of the committee was to raise a fund to give help to students of exceptional promise to enable them to enter upon a medical course in the medical school of the University College at Cardiff. The fund would be used to assist students mainly in the fourth and subsequent years of their training, and in special cases to make small loans. The committee would take into consideration the academic record, health, personality, and general fitness of the applicants, as well as the financial position of the parents. Mr. Thomas urged that women were specially fitted for posts as medical inspectors of school children and the treatment of defectives, and women; they were also well suited to act as resident medical officers of many institutions. There was also a call for their services in the Crown Colonies and in mission work. The committee proposed to represent to some of the intermediate schools for girls that they should apply to the medical authorities for the recognition of their laboratories as places where biology, as well as physics and chemistry, might be taught, so that girls intending to be medical students might while at school prepare for the preliminary scientific examinations. Principal Griffiths said that the movement had not originated in the college, which, however, welcomed it, as there was a general feeling that something of the kind was wanted. Professor Hepburn, dean of the faculty of medicine, University College, Cardiff, also supported the proposal, and a resolution in the sense indicated was carried unanimously after Sir Henry R. Reichel, principal of the University College of North Wales, Bangor, had urged that a loan fund would be preferable to the establishment of scholarships. It was announced that Lord Kenyon had consented to be president of the committee, and a number of vice-presidents were chosen, including the Countess of Plymouth and Ladies Aberdare, Tredegar, and Varney. Miss Mabel Howell (Cardiff) was elected honorary secretary, and Lady Owen Philipps honorary treasurer.

SMALL-POX AND TUBERCULOSIS.

The Salford Insurance Committee has for the third time since the Insurance Act came into operation been placed at a serious disadvantage in dealing with tuberculous patients by the outbreak of small-pox in the borough. For six years before the Insurance Act there had not been a single case of small-pox, and by the permission of the Local Government Board the Public Health Committee was allowed to use the Drinkwater Park Small-pox Hospital for tuberculous patients so long as it was not required for small-pox, and the Insurance Committee by virtue of its contract with the Health Committee had recently about thirty insured persons suffering from tuberculosis in the hospital. On the occurrence, about a fortnight ago of a case of small-pox in Broughton, the medical officer of health first tried to obtain admission for the case into some other small-pox hospital, but no other authority could be found to take it, and it was then necessary at once to turn out all the tuberculous patients from Drinkwater Park Hospital to make room for the small-pox case and for contacts. The Salford Corporation some time ago completed plans for a large new sanatorium at Marple, and the sanction of the Local Government Board had been obtained, but the Treasury stepped in and forbade the work to be commenced at present owing to the war. The Public Health Committee is bound by its contract with the Insurance Committee to do all it can to find accommodation for insured tuberculous patients admitted to sanatorium treatment, and beds have been found for several of the displaced patients at the Crossley Sanatorium and the Bowdon Home, but the majority have had to be sent to their own homes, and to be content with dispensary or domiciliary treatment. No blame can be attached to the local authorities, but it is a most unfortunate thing that for the third time in three years so many insured tuberculous patients, as well as a

number of others non-insured, should have had to be displaced for the sake of a very small number of small-pox cases. Up to the present only four or five cases have occurred, but one has died, and there were a large number of "contacts"; in the best event it will not be possible for any tuberculous cases to be readmitted to the hospital for some weeks, and it appears to be impossible to find accommodation for more than a very limited number at other sanatoriums.

A PUBLIC MEDICAL SERVICE.

At the annual meeting of the Leicester subdivision of the Union of Medical Practitioners and of the Leicester Public Medical Service worked in conjunction therewith, it was stated that practically the whole of the medical profession in Leicester are members of the Union and about three-fourths are on the panel for State insured persons and are acting members of the Public Medical Service. The Union is intended to ensure uniform action to be taken in the interests of medical men, to effect insurances, and to collect debts on favourable terms. The meeting adopted a scheme which had been carefully considered to provide for the attendance on patients of doctors engaged on military service and to safeguard the interests of the absentee doctors.

The subscribers to the Public Medical Service, chiefly women and children, number about 43,500. In addition, the friendly societies in Leicester have made arrangements for their members to avail themselves of the services of the doctors on the Public Medical Service list. The chief societies have their own dispensaries and pay certain rates per annum to the Public Medical Service for medical attendance on their uninsured members and their wives and children, who are included in the above total of 43,500, and in addition for about 12,000 of their members who are State-insured. The service has a central dispensary and offices with eight branch dispensaries, and there are eye, nose, ear, and throat and dental departments in connexion with it; subscribers may consult specialists on payment of moderate fees. Arrangements have been made with the local education authority for the purposes of the school clinic, and 1,644 school cases have been treated during the year. Also there is an arrangement with the board of guardians whereby the necessary medicines for the outdoor sick poor of Leicester are dispensed by the Public Medical Service. The total number of prescriptions dispensed for the various sections during the year was nearly 230,000. The sum collected from subscribers to the service was £8,558, and payments from friendly societies, guardians, and other sources, brought the total income for the year to over £15,000. After all expenses had been defrayed, the sum of £11,430 was distributed among the medical officers and specialists for attendance on subscribers.

It would be of interest to know how these payments compare with private practice and with the sums received by panel practitioners for insured persons.

Ireland.

SIR CHARLES CAMERON has published some statistics as to the work of food inspection in Dublin, and to show their significance has compared them with similar work in Sheffield, the population of Dublin being 310,467 and that of Sheffield 476,971. The number of analyses of food and drugs in Dublin was 4,075, in Sheffield 1,037; 146 prosecutions were instituted in Dublin, and the penalties imposed amounted to £386 7s. 6d.; in Sheffield the number of prosecutions was 35, and the penalties amounted to £39 17s. 6d.

The fortieth annual report of the Incorporated Orthopaedic Hospital of Ireland, read to the annual meeting last week, stated that the hospital now had accommodation for 79 patients in Upper Merrion Street and 66 in the country at Templeogue. During the year 162 children were under treatment, 52 were discharged cured, 30 improved, and only 1 died; 75 remained under treatment. The average number of beds in daily occupation was 71, and the average residence in hospital 160 days. The annual subscriptions and donations were £177 less than

last year. The sum of £692 had been spent during the year on additions and improvements.

CEREBRO-SPINAL MENINGITIS.

At the last meeting of the Ulster Medical Society, Captain W. J. Wilson, M.D., read a paper on the epidemiology and bacteriology of cerebro-spinal meningitis. He rejected the pleomorphic explanation chiefly advocated by Hort, and advanced evidence in support of the theory that infection by the meningococcus in some way lowered the resistance of the intestinal wall, and allowed secondary infections from the intestine, of which he mentioned several, and gave the agglutination results. In the epidemic of cerebro-spinal fever some years ago Professor Symmers always found the mesenteric glands inflamed. Out of 900 contact cases that Dr. Wilson had examined in soldiers he found eighty carriers, but not one of these developed the disease. Dr. Wilson thanked Dr. Georgina Darling, Lieutenant Purce, Dr. Gardner Robb, and the residents at the Purdysburn Fever Hospital for their valuable help. At the same meeting a number of specimens were shown, and Dr. Calwell read a short paper in which he laid stress on the fact that cardiac murmur was often heard in the supine position, which sometimes entirely, sometimes to a great extent disappeared in the erect. He emphasized the importance of this fact in life assurance and examinations for the services.

IRISH AUTOMOBILE CLUB AND THE WAR.

The report of the Irish Automobile Club is a splendid record of voluntary work done for the benefit of the soldiers, especially the wounded. The club has four ambulances on service in France, and a number of members have had their cars converted into ambulances for use on the arrival of hospital ships in Dublin. A great many members are giving their cars up almost entirely for military purposes. Some months ago the D.D.M.S., Irish Command, sent a letter of thanks to the club, in the course of which he spoke of "the unostentatious way in which the Automobile Club carries out this humane and patriotic self-imposed work." The work done by the members of the club include ambulance service, railway station buffets, reception of wounded soldiers on sick furlough, assistance of recruiting, help to the Army Forage Committee, and the entertainment of soldiers in the Dublin hospitals. Much of the work for the wounded and travelling soldiers was done under very trying conditions, but no matter how bad the weather was at Kingstown Pier or at the North Wall, there were ladies and gentlemen working in the early hours of the morning. No less than 170,000 meals have been provided for soldiers and sailors at these buffets since they were opened.

CORK SOUTH CHARITABLE INFIRMARY.

The report of the South Charitable Infirmary and County Hospital, Cork, for 1915 records another year of successful work. In the medical wards 633 patients passed through the wards; 577 were discharged cured, while 42 died, of whom 22 were hopeless on admission. There were 50 cases of pneumonia, and 4 of these had a fatal ending.

In the surgical wards 675 cases were treated, of whom 608 were discharged cured and 27 died, several of these being young children who succumbed to the shock of severe burns. The large number of 4,115 new cases passed through the extern departments, with a total attendance of 15,607. In the early part of the year the wounded soldiers admitted in October and November of 1914 were all discharged recovered; 30 more wounded were admitted in April, 1915, and two men rescued from the ill-fated *Lusitania* and two seriously injured in the sinking of the *Arabic*.

An interesting incident of the annual meeting at which the report was read was the presence of the new Lord Mayor of Cork, himself a member of the staff of the institution. The Right Honourable T. J. Butterfield was most heartily congratulated on the honour conferred on him by his native city, and wished by his colleagues and friends a very prosperous year of office. Several of the younger members of the medical staff have been accepted for war work, some in the R.A.M.C. and one as civil surgeon at Cork Military Barracks. Much regret was felt at the resignation of Mr. Samuel Henry Newson, as treasurer to the institution, a position he had held for twenty-five consecutive years.

BELFAST HEALTH SOCIETY.

The report presented to the annual meeting of the Belfast Health Society, held on February 22nd, stated that during 1915 the attendances of mothers and babies at the babies' clubs organized by the society had numbered 8,422, while 8,864 pints of milk had been given to the mothers for their babies. The society had also established a system of "home helps," who, when the mothers were temporarily laid aside, took charge of the house and children. Sir John Byers, in seconding the adoption of the report, which was carried, said that during 1915 no fewer than 924 new babies had been enrolled in the babies' clubs. Many deaths of infants in the first twelve months of life were due to the fact that they were born prematurely and congenitally weak, and that some had the taint of constitutional disease. To improve this state of things the nation required the help of the medical and nursing professions, of public health authorities, and philanthropic organizations such as the Belfast Health Society. Constitutional disease must, he said, be got rid of by a more thorough investigation of the prenatal conditions, and deaths as a result of accident at birth by improving the science of obstetrics and especially by examination of the mother before the time of her confinement.

Scotland.

At the annual meeting of the Royal Victoria Hospital, Dundee, Dr. R. C. Buist, in seconding the adoption of the report, said that the death-rates from tuberculosis and other early killing diseases had gone down, but those from cancer had risen, so that its alleviation was likely to be a problem for the hospital for a long time. Among the new knowledge and new forces becoming available, which sometimes promised a cure and frequent alleviation in cancer after it had passed beyond the surgeon's skill, was radium. A small stock had been placed at the disposal of the Royal Infirmary by a generous donor, but it was not sufficient for what was needed, and there was room for further handsome donations to purchase radium for the use of hospitals in Dundee.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The Privy Council has intimated approval of the appointment of Mr. D. L. Eadie, 50, George Square, Edinburgh, as Secretary to the Central Midwives Board for Scotland. All communications thereabout should be sent to Mr. Eadie at the above address. Several meetings of the board have now been held, and we understand that one of the matters engaging its attention has been that of filling up the two remaining vacancies on the board by the appointment of two midwives. In the Act it is left in the hands of the Lord President of the Council to fill up these places when the number of midwives qualified is sufficient. The position of a midwives board without midwives on it may be felt to be something of the nature of the play of *Hamlet* with the part of the Prince of Denmark omitted. The board in Edinburgh has shown its anxiety to pass as quickly as possible through an incomplete stage in its development, and has, it is understood, petitioned the Lord President to fill up the vacant places. The difficulty is the absence of a midwives roll for Scotland, but it is hoped that as soon as a sufficient number of women have been put on the roll—and there seems no reason why that should not be soon—the two midwives will be chosen and the board completed. It has been further arranged that the two boards, the one for England and that for Scotland, shall exchange minutes.

India.

THE LONDON MISSION HOSPITAL, JAMMALAMADUGU.

From the annual reports of the London Mission Hospital at Jammalamadugu, in Southern India, for the five years 1910 to 1914 inclusive, it appears that the mission staff consists of two European medical men and a nursing superintendent, with a number of Indian dispensers, dressers, and nurses.

A small medical school, with eighteen or twenty students, is carried on in connexion with the hospital. At the beginning of 1910 there were 50 beds in the hospital at head quarters, and two small branch dispensaries had 4 beds each. A third branch was opened in February, 1910, and a fourth in October, 1914, while in November, 1913, Surgeon-General Bannerman, C.S.I., of Madras, opened a new ophthalmic wing at the head quarters hospital; by the end of 1914 there were 79 beds there, and 6 at each of the four branches, providing accommodation for 103 in-patients in all. The total number of in-patients treated in 1910 was 1,006, and in 1914 had risen to 1,229; of out-patients, 14,761 in 1910, rising to 16,203 in 1912, but falling again to 14,621 in 1914. The total number of operations, major and minor, rose from 1,642 in 1910 to 2,819 in 1914. The numbers of the more important operations performed during the whole period of five years were: Cataract extraction, 641; litholapaxy, 20; lithotomy—suprapubic, 15, others, 4; prostatectomy, 6; abdominal operations, 102; malignant tumours, 120. Operation for cataract is done chiefly by Smith's method, extraction in capsule. The great majority of the patients were Hindus, but a considerable number of Mussulmans, and, especially at head quarters, of native Christians, were also treated. We learn from the reports that malaria is uncommon in the tract of country served by the mission, dysentery and tuberculosis common. The mission seems to do much good in an out-of-the-way part of India.

Correspondence.

THE NOTIFICATION OF MEASLES.

SIR,—The letter of Dr. Garrett in your issue of February 19th is interesting from the point of view of a whole-time M.O.H., but the part-time M.O.H. is in a more invidious position.

Formerly the notification of an infectious disease came invariably from a doctor, and the subsequent visit of the M.O.H. was quite impersonal, to deal with the discovery, of the source of the disease, to take steps for the prevention of the spread of the infection, usually by the removal of the case to an infectious hospital, and to attend to any existing sanitary conditions. The regulations of the Local Government Board regarding measles alter the whole situation. As Dr. Garrett says, the chief object of the notification of measles is or ought to be to prevent the death of children from the disease, that is, that they ought to have medical attendance; but there is nothing in the regulations that is effective to this end; it is not stated, though it may be tacitly implied, that it is any part of the duty of a M.O.H. to give personal advice as to what steps should be taken as regards the treatment of a case, even as to whether any treatment by a doctor should be suggested—a more important matter than the discovery of the source of infection which is probably obvious, or than the limitation of the spread of the infection, which may present difficulties.

The difficulties of the part-time M.O.H. are more complicated; if we suppose that the notification arrives from parent or school teacher in respect to a patient in the practice of the M.O.H., and on a visit of inspection their diagnosis proves to be correct and he advises that a doctor be called in, he is obviously placed in the unpleasant position of touting for custom, and the parent may also assume that as the first visit was official and cost nothing, subsequent visits ought to come into the same category or else be dispensed with.

As 95 per cent. of the children who have measles in a rural district never see a doctor, the latter solution would probably be adopted by the parents. Another difficulty that confronts the part-time M.O.H. is that most country practices overlap, and that notifications from parents and school teachers may arrive in respect to people who for various reasons may not previously have selected a doctor, the M.O.H. may then have to decide whether he will suggest himself as a suitable person to attend the case, or be sufficiently magnanimous to pass it on to one of his colleagues, and, if so, which one. The school teacher must always play an important part in the working of the regulations. Since they came into force I have received

one notification from a doctor and five from school teachers of suspected cases, none of which were measles; in four out of the five cases I subsequently discovered that doctors were attending. These cases only involved a journey of nine or ten miles there and back, but had they occurred in other localities they might have involved a journey of fifty miles there and back.

The chief result of the regulations will be to put an enormous amount of extra work on all medical officers of health and their officials without any corresponding result; it is almost impossible to prevent the spread of the infection of measles by a wholesale isolation of children, and it is difficult to see that the regulations will provide for the proper treatment of more than a very small proportion of the cases, as the children below school age will probably not be notified by their parents.—I am, etc.,

A PART-TIME M.O.H.

THE PHYSICS OF A SURGICAL DRESSING.

SIR,—In the recent correspondence on the treatment of septic wounds I do not think that sufficient attention has been paid to two important principles which should guide one in the inquiry as to the best method of treating these wounds—namely, antiseptics and osmosis.

Most observers have been satisfied with finding a suitable antiseptic, but they have omitted to take into consideration the necessity of providing for some drying-up process which shall be exerted on the wound from start to finish. For the past year I have been using a 20 to 50 per cent. of ichthyol in glycerine painted on the wound and surrounding skin once daily. This combination fulfils the above mentioned conditions, does not adhere to the surface of the wound, and places the wound in a more favourable condition for healing than other methods. Those who find it difficult to procure ichthyol, or consider it too expensive, can easily substitute some cheaper antiseptic of a non-irritating character.

I am in absolute agreement with Lieutenant-Colonel Primrose as to the undesirability of applying impermeable material over a wound. I have used oiled silk by way of experiment, and soon learnt to discard it. For the first two days it did not appear to exert any marked influence, but if retained longer, healing was invariably delayed.

I am no believer in a wet dressing at any stage in the treatment of a wound; it deserves equal condemnation with oiled silk, etc. Why this antiquated absurdity is still retained any more than drainage tubes in septic wounds is a great mystery to me.

The placing of a septic limb in a bath is to my mind the height of folly; it delays healing indefinitely, and may lead to amputation. I am quite convinced that if ichthyol and glycerine are used in these cases many limbs will be saved at the front and in this country.—I am, etc.,

C. W. DUGGAN,

Military Hospital, Lincoln, Feb. 24th.

Major R.A.M.C.

SIR,—Like Dr. Shirlaw, I have often seen the evil effects of the application of dry dressings to septic wounds, and many will hope, with him, that we shall not depart from the principle of using dry dressings for aseptic wounds, and moist dressings covered with impermeable material for all septic injuries.

I have often seen dry dressing removed from a septic wound almost well, but in taking off the dressing a collection of pus was to be seen on the area of the dressing corresponding to the wound, and sometimes a gush of pus. The discharge had not spread laterally in the dressing, as a result of no outside impermeable material. Moreover, the new epithelium at the edges is frequently torn unless time and trouble are spent in moistening the wound.

A septic finger in an early acute stage needs a warm wet dressing (1 in 20 carbolic, 5 per cent. lysol, etc.), covered with oil silk. I have had them in my own person, and know their comfort. After incision wet gauze covered with oiled silk or jaconet is incomparably more comfortable than a dry dressing. A case I visited just after reading Lieutenant-Colonel Primrose's letter was a good illustration. A lady had a tube tied in the gall bladder, and as she complained of the moistened gauze and wool getting dry and the discharge escaping at one edge of the dressing and not soaking into the latter, I directed her to apply jaconet. On my next visit I was met with the remark,

"I have had no discomfort from the dressing since the addition of the jaconet"—the dressing had taken up the discharge in a uniform manner.

It is sufficient, in a clean wound covered with gauze and then with layers of aseptic wool, to use the impermeable covering a size smaller than the underlying layers, for the discharge, taking, as it does, the shortest line to the surface, finds its way to the jaconet and then perforce spreads laterally and diffuses itself through the dressing.

There will be numbers who most assuredly will disagree with the statement that "it would be greatly to the advantage of the wounded if impermeable oil silk, etc., were removed from the armamentarium of the army." The economy occasioned by the use of tissue is also a point. Antiseptic wools can be used again so far as those parts untouched by discharge are concerned.

As a wound progresses towards recovery it is true that a layer of non-absorbent wool over moist absorbent wool has much the same action as jaconet, and pus meeting it is thrown laterally. I remember reading a very interesting article by a Norwegian surgeon, wherein he spoke of hydrophil and hydrophobe wool, the former being placed next the wound and the latter outside all.—I am, etc.,

Norwich, Feb. 28th.

HENRY C. NANCE, F.R.C.S. Eng.

BREADS FOR CHILDREN.

SIR,—By the theory of existence of vitamins in all cereals, the Japanese scientists "built better than they knew," for not only does the discovery reveal the cause of beri-beri, but goes a long way towards solving our own food problem. The manifest deterioration in physique of our rural population, the wretched teeth possessed by 90 per cent. of the children, the prevalence of various developmental defects, can only be accounted for by insufficient nourishment, and the most unobservant must be startled by the fact that, in spite of a lowered standard, more than 30 per cent. of the young men attesting have been rejected as medically unfit. When we reflect that bread made of roller-milled flour—destitute of vitamins—with a little cheap jam, forms the chief dietary of the majority of these children, the inference is obvious that henceforth the white bread in general use may be fairly classed with polished rice, for besides being poor in fats, and minus nearly two-thirds of its minerals, it has been deprived of the all-important germ, which is sold to the makers of the various "gorm breads" on the market. As to remedies, the whole matter hinges on the methods of milling; it resolves itself into a question of roller v. stone compression or grinding. There can be no doubt as to the answer, for rollers have the fatal defect of flattening the glutinous germs into discs, which cannot pass through the screen and are lost, whereas with stone mills everything is retained. The profession surely ought no longer to acquiesce in this state of affairs. It is our duty, in the matter of food, to insist on nothing short of the best, nor rest content till there is placed within the reach of every man, woman, and child in the realm bread which shall be in fact, as well as in name, the "staff of life."—I am, etc.,

Brockenbush, Feb. 28th.

HENRY J. HIBBERD.

AUSCULTATION OF THE HEART OF THE RECRUIT.

SIR,—In your issue of November 20th Sir James Kingston Fowler gave extracts from an article of his written some years ago. There was much in these extracts which will appeal to every one, but on one point there must be a difference of opinion. It is when he says:

A murmur which suddenly and completely disappears when the patient lies down, provided there is not at the same time any marked alteration in the pulse-rate, is almost certainly due to organic disease of a valve.

And again:

Functional and false murmurs often disappear when the patient lies down, whilst an organic murmur, especially that of mitral stenosis, may be only audible in that position.

The letter called forth one from Sir James Mackenzie. With the subject of their difference of opinion I am not here concerned, but I see in your issue of December 25th, 1915, p. 943, that Sir James Kingston Fowler repeats his belief that "Loud murmurs often disappear when the patient lies down."

Surely, as an indication of some leakage or obstruction

which throws more work on the heart muscle, murmurs have their place, and it is as important as ever to distinguish between those murmurs produced by an organic valvular lesion and those due to some temporary and passing condition. In endeavouring to make this distinction, the effect of posture is of great importance, and I would venture to say that the so-called "functional murmurs"—which, by the way, are always systolic in time—tend to be louder in the horizontal posture, and become less audible and even disappear completely in the vertical. Systolic bruits due to organic disease vary in the same way with posture, but to a much less extent. It will be seen that this is the exact opposite to what Sir James Kingston Fowler states, and I can only leave it to your readers to decide. I would ask any doubter to go round any ward and listen in the second and third left interspaces close to the sternum of patient after patient, each patient being recumbent. A systolic murmur will be heard in a great many of them, and it will be especially loud at the end of expiration. In each instance, when a murmur has been detected, get the patient to sit or stand up, and it will be noticed that the murmur will tend to lessen, or even disappear. This pulmonary systolic murmur is, of course, the commonest type of "functional" murmur, but the effect of posture will be also found to apply to those in other areas. These very common functional murmurs are of little or no significance, and have no bearing on the patient or the recruit's "fitness" for active service. If it were only generally realized that they mean nothing, soldiers who come to the base hospital labelled "valvular disease of the heart" would be able to remain with their units, and thus they would be saved much worry and the Government much expense. In the same way many recruits would be accepted who at present are rejected.

May I add in closing how thoroughly I agree with the view that all men should be examined both in the recumbent and in the vertical postures? This not so much for its bearings on murmurs as its effect on the heart-rate. In all doubtful cases they should also be examined after a definite amount of exercise. This routine is always carried out in this base hospital, and is constantly found to be of great value.—I am, etc.,

ROBERT DAWSON RUDOLF, M.D. Edin.,
F.R.C.P., Lieut.-Col. C.A.M.C.

British Expeditionary Force, France, Jan. 1st.

Universities and Colleges.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

M.B., CH.B.—O. C. M. Davis, Hilda K. Ewins. *Part I (including Forensic Medicine and Toxicology)*: E. J. Ball.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—*W. J. May, *H. S. Mitchell, *L. F. Pain, *G. C. N. Younger.

MEDICINE.—*E. V. Beaumont, *H. M. Gray, *L. Kahan, *W. J. May.

FORENSIC MEDICINE.—J. Y. Dent, P. C. C. Fenwick, H. M. Hobson, G. C. N. Younger.

MIDWIFERY.—P. G. H. Baron, W. F. R. Castle, B. Ghobrial, E. N. Glover, W. H. A. Pratt, A. L. Watts.

* Section I. † Section II.

The diploma of the Society has been granted to the following: W. F. R. Castle, L. Kahan, W. J. May, and G. S. Mitchell.

The Services.

EXCHANGES DESIRED.

CAPTAIN H. W. BAYLY, R.A.M.C.T., 2/1st South-Western Mounted Brigade Field Ambulance, Maresfield Park Camp, Uckfield, Sussex, gazetted Captain September 4th, 1915, late Civil Surgeon, General Plummer's Force, South Africa, wishes to exchange with a Medical Officer to a British Cavalry or Yeomanry Regiment in France.

Captain R.A.M.C.(T.F.), honorary surgeon to civil hospital at present stationed in England, attached as Medical Officer to Divisional Train, A.S.C., desires an exchange with an officer holding a hospital appointment at home or abroad in which operative surgery is available.—Address No. 950, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Obituary.

NATHANIEL E. ROBERTS, M.B., C.M. Edin., D.P.H.,
ASSISTANT MEDICAL OFFICER FOR THE PORT OF LIVERPOOL.

WE regret to announce the death of Dr. N. E. Roberts, which took place at Menai Bridge. Until twelve months ago he was enjoying life and fulfilling his various public duties with his customary energy. His health gradually began to fail and he was reluctantly compelled to retire from active practice. For some months he had lived with his sister, and it was hoped the rest in his native land would restore his health. Dr. Roberts was a good example of self-help and dogged perseverance. In his early youth he worked as a pork butcher, then he qualified as a chemist, and finally by his indomitable energy studied medicine at the University of Edinburgh, where he graduated M.B., C.M. in 1879. He took the D.P.H., L.R.C.P.S. Edin. in 1892. After spending some time at Bangor he went to Liverpool where he held many public appointments. He was recognized as an authority on infectious fevers, having gained his experience during the twenty-three years he was visiting physician to Grafton Street Fever Hospital. He was also assistant medical officer to the Port of Liverpool; his duties were to visit ships arriving in Liverpool and inspect the bills of health and detect and deal with any source of infection. He was also an examiner in and teacher of vaccination and lecturer on infectious diseases in the University of Liverpool; at one time he was Vice-Chairman of the Medical Faculty.

Dr. Roberts was an enthusiastic volunteer and territorial, retiring with the rank of Lieutenant-Colonel R.A.M.C. (T.F.).

A man holding so many public appointments had little time for private practice, and this partook more of consultations in the special subjects on which he was an authority than of general practice. Nevertheless Dr. Roberts was a man who never narrowed his interest in matters medical, and was a frequent attendant at the meetings of the Liverpool Medical Institution.

He had many friends, won for him by cheerful genial disposition and sense of humour, and, in spite of a rugged impression, rendered more noticeable by his shaggy eyebrows and massive hair, he was always welcome among his medical friends, and many a joke about his fellow countrymen and their ways passed his lips. He was a widower, and leaves no children. The funeral, at Smithdown Cemetery on February 23rd, was attended by representatives of the public institutions with which he was connected.

By the death of Mr. CHARLES LAKIN on February 10th, at the age of 67, Leicester loses one of its oldest medical practitioners. Mr. Lakin was educated for the medical profession at Queen's College, Birmingham, and after taking the diploma of L.R.C.P. Edin. in 1872 was for a time resident obstetrician at Queen's Hospital. Later he took the diplomas of L.R.F.P.S.G. and L.S.A. He commenced practice in Leicester in 1873 and quickly attained a prominent position. For the last thirty years he had been a member of the town council, and in 1892 was appointed an alderman, a position which he held at the time of his death. His best known public work was in connexion with the Sanitary Committee, of which he was vice-chairman for many years; he was also chairman of the Isolation Hospital Committee. He was Mayor of Leicester in 1908, an office that he filled with dignity and credit to the town. Of quiet, unassuming character, he spoke seldom, but rendered splendid service by bringing his medical knowledge to bear on questions relating to the welfare of the rapidly growing borough. Among his multifarious duties he found time to carry on the work of the honorary medical officer to the Wycliffe Society of the Blind, which looks after the interests of over 200 blind persons. Of genial nature, his patients found him full of kindness and sympathy, and many will mourn the loss not only of a trusted medical adviser but of a valued friend.

DR. GEORGE ALFRED HEBERDEN, D.S.O., of Victoria West, Cape Province, South Africa, died in a sanatorium on January 23rd, aged 55. He was the eldest son of the

late Rev. George Heberden, vicar of Rothwell, Yorkshire, received his medical education at St. George's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1888. Settling in South Africa, he served as surgeon-captain with the mounted forces in the South African war, went through the siege of Kimberley, and received the D.S.O., as well as the medal. He was afterwards district surgeon and railway medical officer at Victoria West.

MAJOR FREDERICK RICHARD MILLER, R.A.M.C.(T.F.), Deputy Assistant Director of Medical Services, 60th Division, died at Alum Chine Towers, Bournemouth, on February 4th, aged 50. He was the younger son of the late T. Lanfear Miller, of Cape Town, was educated at St. Bartholomew's, and took the diplomas M.R.C.S. and L.S.A. in 1886, and that of L.R.C.P.Lond. in 1887. He graduated M.D.Brux. with distinction in 1889. He was clinical assistant in the Royal Ear Hospital, and before the war was in practice in Kensington; he was a captain in the 6th London Field Ambulance, and was appointed to his late post on February 22nd, 1915. He was an ex-president of the Brussels Medical Graduates' Association and a member of the Red Cross Society of Madrid.

LIEUTENANT WILLIAM DENMORE MURRAY, R.A.M.C., died in London in January, aged 48. He was educated at Glasgow University, where he took the degrees of M.B. and C.M. in 1888, and had been in practice in London for fifteen years, when he took a temporary commission in the R.A.M.C. He had recently been stationed at Colchester. He leaves a widow and two sons, the elder of whom is serving in the Northumberland Fusiliers.

Medical News.

THE University Court of Edinburgh has elected Dr. R. McKenzie Johnston a Curator of Patronage in the room of the late Sir William Turner.

H.R.H. the Duke of Connaught, Grand Prior of the Order of St. John of Jerusalem in England, has approved of the appointment of Sir William Bennett, K.C.V.O., F.R.C.S., to be Surgeon-in-Chief to the St. John Ambulance Brigade.

PROFESSOR M. WEINBERG, of the Pasteur Institute, Paris, will deliver a lecture on bacteriological and experimental researches on gas gangrene, with epidiascope demonstration, before the Royal Society of Medicine (1, Wimpole Street, London, W.), on Friday next, at 5 p.m.

THE Health of Munition Workers Committee has issued a memorandum on canteen construction and equipment numbered 6 (Cd. 8199. Price 4d.), which is an appendix to memorandum 3 on industrial canteens. The new memorandum is illustrated by detailed constructional drawings. Communications on the subject should be addressed to the secretary, Canteens' Committee, Central Control Board, Canada House, Kingsway, London, W.C.

THE Royal Free Hospital has made its clinics for safeguarding infant life the consultative centre of departments devoted to infant welfare. An appeal is now made for £200,000 for additional accommodation for maternity and other special cases. A generous benefactor has already presented over an acre of ground adjacent to the hospital, and the first block of the new building will be commenced as soon as funds and circumstances allow. Donations should be addressed to Sir Francis Layland Barratt, Bt., M.P. (honorary treasurer), Royal Free Hospital, Gray's Inn Road, W.C., where full information can be obtained from the secretary, Special Appeal Fund.

AT the annual meeting of the Southport Infirmary on February 26th a tribute to the memory of Sir George Pilkington, adopted by the board of management, was reported. The resolution recalled that he had been chairman of the board for fifteen years, and concluded as follows: "Sir George's relations with his colleagues and the entire staff were always of the most cordial nature, and he enjoyed the confidence and affection of all. In him the infirmary has lost a leader of wisdom and resource, and a friend whose generous help was ever available. His memory will long be a stimulus to those who remain to carry on the work for the sick poor of this district, and especially at this time for the wounded soldiers who are entrusted to our care."

THE Pirogoff Society, the leading medical society of Russia, in a recent report states that the suppression of the drink traffic has led to a diminution of sickness, especially venereal and mental diseases, accidents (especially railway), fires, suicides, and crimes; and to an increase of industry and material wealth. Whether a return to beer and wine should be allowed while vodka continues to be forbidden is answered in the negative on the ground that these drinks, being pleasanter to the taste, attract women and children. Other measures to supplement prohibition are urged, such as a betterment of social conditions and an active propaganda for the enlightenment of the people regarding the evils of alcoholism. An inquiry made in the province of Penza showed that only 14 per cent. of former drinkers had used substitutes, and most of these were comparatively harmless beverages.

MR. LEWIN PAYNE opened a discussion at the meeting of the Odontological Section of the Royal Society of Medicine on February 28th on war injuries of the jaws and face. Communications were made by Dr. Hayes of the American Ambulance in France, Dr. Hotz of Paris, and Mr. J. F. Colyer. The debate will be resumed on Monday next at 5.30 p.m. In connexion with the discussion an exhibition of splints, models, photographs, and x-ray pictures is on view at the house of the society (1, Wimpole Street). M. Pont of Lyons has sent photographs and descriptions of cases of very extensive destruction of the jaws and face, and specimens of the apparatus used. The American Ambulance in France and the Ecole Dentaire de Paris have sent similar exhibits. The photographs show well the form of splint used and the permanent restorative apparatus. There are similar exhibits from the British hospitals, including x-ray pictures of two cases of bone-grafting of the mandible operated on at the Croydon Military Hospital. The exhibition is of the utmost practical interest, and remains open till Monday evening, March 6th.

THE Territorial General Hospital at Birmingham has followed the example of some others, and on January 1st issued the first number of a hospital periodical, with the title *The "Southern" Cross*. The 1st Southern General Hospital was established in the university buildings, Edgbaston, Birmingham, with 520 beds, and received its first convoy on September 1st, 1914. The number was subsequently raised to 1,040; sections were opened at Dudley Road, Stourbridge, Selly Park, and King's Heath; forty-seven auxiliary hospitals were organized, and many civil hospitals in the Midlands put beds at the disposal of the 1st Southern. Altogether 30,501 patients, of whom 235 were officers, were treated to the end of 1915. The first number opens with a portrait of the administrator, Lieutenant-Colonel F. Marsh, and a short note by him, in which he very justly observes that the work of such hospitals does something more than relieve suffering, for restoration of the sick and wounded to health means the return of trained soldiers to the firing line. Like its hospital contemporaries, this periodical is not all serious; in fact, it is very little serious. It contains a good many hospital jokes and some excellent caricatures. It is edited by N. Pollock, whose rank is not stated.

AT the usual monthly meeting of the Medical Sickness and Accident Society, on February 18th, when Dr. F. J. Allan was in the chair, it was reported that the sickness experience for January was slightly in excess of the expectation at this time of the year, and was generally accounted for by the number of claims for influenza. Special reports on all the chronic claimants now drawing sickness benefit showed that they numbered 40 and that the amount paid annually was £2,000. This is considered to be the most important work the society performs, as it is principally the sickness benefit received each week that enables the recipients to maintain themselves and their families. The votes obtained in consequence of the annual subscription of £105 to Epsom College has also enabled members of the society, crippled in health and unable to earn their living, to obtain Foundation Scholarships for their sons, thus giving them a first-class education at one of the foremost schools free. The balance-sheets for the year showed that the total funds of the society were now £274,700 and the annual income £37,000. It was resolved to place before the annual meeting in March a scheme of deferred annuities, starting at age 65, with five options before that age. Registered dental surgeons of military age are accepted under certain conditions which will be given on application. All applications should be addressed to the secretary, Medical Sickness and Accident Society, 300, High Holborn, London, W.C.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitoliway, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

QUERIES.

INCOME TAX.

J. M. states that the separate income of her husband is probably under the exemption limit, and that their combined incomes do not exceed £500. Should separate returns be made?

* A recent Finance Act provided that a married woman might be assessed separately where notice requiring that method to be adopted had been given in due time. "J. M." is now too late to make that claim for 1915-16, but might send a note to the local surveyor of taxes, asking for any appropriate form of claim to be sent to her for the year 1916-17. The fact that separate returns are made does not affect the amount of the total allowances to be made, but the resulting assessments should be more convenient and be more easily verifiable by "J. M." when the notices are issued next autumn. Assuming that "J. M.'s" earnings are independent of those of her husband, the abatement (or exemption) would apply as if she were a femme sole.

T. R. A. has been asked by the surveyor of taxes to supply him with a statement showing his receipts and expenses for the year 1915.

* From the extract quoted the letter of the surveyor would appear to refer to the next assessment to be made, namely, that for the financial year 1916-17. Presumably the request is made with a view to agreeing our correspondent's liability with him before the return forms are issued for 1916-17. "T. R. A." is not under any statutory obligation to comply with the request, but we may perhaps say that we understand that the surveyor's procedure is not unusual. If the amount to be returned for assessment be agreed beforehand, the possibility of an estimated assessment being made is eliminated, and therewith the risk that our correspondent may ultimately be required to produce the statement in question in connexion with an appeal.

THE TREATMENT OF PRURITUS ANI.

A. E. asks as to the treatment of pruritus ani with surrounding eczema in a man of gouty habit, aged 50. General treatment and diet for the gout and many ointments locally, and an operation for haemorrhoids both internal and external, and division of the nerves on both sides have been tried during the last three years. The irritation is no better and is only relieved by cocaine locally.

* An instructive series of letters on this subject will be found in the JOURNAL, vol. i, 1914, following a surgical memorandum by Dr. J. Cropper, p. 966. One correspondent declared that, according to his experience, about five or six applications of x rays will cure any case which is not merely a complication of polypus, fissure, haemorrhoids, etc. Dr. Cropper, however, replied (p. 1330) that few people will use x rays if they can get relief from simpler remedies. The local treatment, advocated by Dr. Cropper and also successfully carried out by a medical patient suffering from severe chronic pruritus, was the application of tincture of iodine in full or half strength, three times weekly. Compound tincture of benzoin, painted on the parts twice or three times daily, is said to be even more efficacious after several applications of iodine, which should be reapplied from time to time when found necessary.

LETTERS, NOTES, ETC.

COLONEL RIORDAN, R.A.M.C. (ret.), has reduced the price of his *Manual for Army Medical Services* (London: Eyre and Spottiswoode) to 3s.

WITH a view to liberating Russia from the yoke of dependence on German trade, the Russo-British Trade Exchange Company has published a *Directory of British Manufacturers for Russian Trade* (5s.). It furnishes the Russian consumer and tradesman with an authentic directory of British manufacturers, printed in the Russian language, with trade headings in Russian and English, and copious advertising

pages. The book is well got up and illustrated, and is designed for circulation in Russia. So far as we can judge, it has received the support of many of the most representative British manufacturing houses. It fills a want that has been cried aloud for many months by all our British writers and authorities on Russian affairs, and we wish it all success.

"URODONAL."

WE have received for examination a sample of a granular effervescent preparation made by J. L. Chatelain (Paris) and put forward under the name "urodonal" for the treatment of rheumatism and all uric acid troubles. It is stated to contain hexamine, lysidine, and quinate of piperazine; it is in the form of large dry granules, which dissolve in water with slow effervescence. Analysis showed the presence of a substantial amount of hexamine, together with a much smaller quantity of a base or bases of the group represented by piperazine and lysidine. Hexamine, it will be remembered, is the term used in the *British Pharmacopoeia* of 1914 for hexamethylenetetramine, a synthetic drug to which a great number of names have been given, including formamine and urotropine. Lysidine is ethylene-ethenyl-diamine, and is nearly related, both chemically and in its properties, to piperazine, which is diethylene-diamine. Piperazine usually dissolves the uric acid in a test tube, but it is very doubtful whether it exercises any such solvent action in the body. The *British Pharmaceutical Codex* states that the amount of piperazine appearing in the urine is very small, and is found to be in combination with the stronger acids and not with uric acid. The antiseptic action of hexamine is exerted only in acid urine. Urodonal appears to be freely advertised to the public in France, and also in this country, as a specific for uric acid troubles. Its composition, however, does not seem to us to justify any very sanguine expectations as to its efficacy in this respect.

THE CLINICAL VALUES OF A URINE TEST GLASS.

DR. C. O. HAWTHORNE (London, W.) writes: In these days of multiplied and costly clinical machines on the one hand and of the need for economy on the other, it may be worth while to note what varied and practical services may be obtained from so simple and inexpensive a piece of apparatus as a urine test glass. In the first place, the glass makes an excellent stethoscope, more particularly when—as cannot always be avoided—auscultation has to be conducted through the patient's clothing. Secondly, if the cylinder is grasped in the physician's hand and the edge of the flattened base used as the head of a hammer, a suitable plexor for heavy percussion is provided, should this mode of inquiry be regarded as necessary. Employed in this same way also the glass is exactly the apparatus required to provoke the knee-jerk and the heel-jerk, as well as the tendon-jerks of the upper limbs, while the "spont" offers itself invitingly when the enterprise of the plantar reflex has to be undertaken. Again, rolled over the surface of the skin, the glass differentiates haemorrhagic and pigment spots from spots due to congestion or inflammation; and, once more, the cylinder is a convenient object for the patient's grasp when intravenous medication or venesection is in progress. All these functions may be added to the particular purpose for which the glass was called into being, and there still remain for gratitude the modest market value of the apparatus and the readiness with which it may be kept in a condition of cleanliness exalted even to the level prescribed by the most rigid of the bacteriological pharisees. I have often demonstrated these utilities to classes of students and practitioners, and perhaps, under the stress of the present economic situation, they may be deemed worthy of introduction to a wider audience.

THE IMMEDIATE TREATMENT OF SEVERE POST-PARTUM HAEMORRHAGE.

DR. W. J. L. FRENCH (Barnetby, Lincolnshire) writes: After an experience of over twenty years in an extensive midwifery practice, I have no hesitation in stating that the most satisfactory and expeditious method of dealing with this urgent condition is to introduce the right hand into the vagina, grasp the uterus firmly, and make pressure against the left hand pressed equally firmly on the fundus externally. There need be no fear of sepsis, except in the minds of the nervous and inexperienced, if the hand has been previously thoroughly cleansed with ethereal soap.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

AN ACCOUNT, WITH COMMENTARY, OF A CASE OF SPLENECTOMY

IN ADDENBROOKE'S HOSPITAL, CAMBRIDGE,

UNDER THE CARE OF

SIR CLIFFORD ALLBUTT, K.C.B., F.R.S.,

L. HUMPHRY, M.D.,
F.R.C.P.,

F. DEIGHTON, M.B.,
M.R.C.S.,

AND

DOROTHY C. HARE, M.D., B.S.LOND.

SPLENIC ANAEMIA, that is, a progressive "secondary" anaemia with enlargement of the spleen, is probably more common than was supposed before the comparatively recent investigations of Sir W. Osler and others drew the attention of the clinician more definitely to its characters. During the autumn of 1915 three cases of this malady came under the care of one of us (C. A.) in the Addenbrooke's Hospital. (Malaria has been unknown in Cambridgeshire for more than forty years.) One of these cases was seen once or twice only and lost sight of; the second was in a little boy (aged 6 or 7) who presented all the now well-known features of the disease. After long consideration it was decided to remove the spleen, an operation to which the mother gave her consent; unluckily however the boy got to hear of our intention and howled until the mother's resolution, not unnaturally, gave way, and he was removed. The case was a severe one; haemorrhages, intestinal and other, were frequent, and probably the boy is no longer living. In this case Dr. Dorothy Hare and Dr. Humphry took much pains to perfect the method of testing for corpuscular fragility, and Dr. Hare, on repeated examinations, found the fragility normal. There was no other point in it of sufficient importance to detain us. The third case was as follows:

Mrs. K., aged 45, was admitted under the care of Professor Allbutt on October 25th, 1915. She was extremely prostrate, blanched, and short of breath. The colour of the face—save some venous injection on the malar bones—and of the whole body was that of an old tallow candle. No discoloration could be found on the skin; indeed the axillary and other folds of the body were, like the skin elsewhere, unusually pallid. No notable emaciation. The mucous membranes were almost as pale as the skin. The teeth were ill kept, two of them loose and protruding. These teeth were drawn without any excessive bleeding; the rest, in consideration of the woman's state, were not extracted, but the mouth was thoroughly cleansed and the gums dressed daily with iodine. There was no definite pyorrhoea. The tongue was pallid, but quite normal in appearance and soft in its substance. The

spleen was moderately enlarged, fairly soft, and a little tender; the notch distinct. No sign anywhere of enlarged lymphatic glands. Excepting haemic murmurs and a very feeble pulse nothing of importance was noted on the side of the heart and blood vessels. The ankles were a little puffy. The liver was apparently normal, but the edge just perceptible below the ribs. No signs and no history of haemorrhages; but occasional passing attacks of diarrhoea or vomiting. From the time of admission onwards the charts showed a continuous pyrexia, as recorded in the annexed reprints of them.

As the woman grew steadily worse, and the occurrence of haemorrhages was feared, it was decided, after careful consultation with colleagues, and especially with Mr. Deighton, to remove the spleen. The patient at last gave her consent, and on December 3rd the operation, to be described by Mr. Deighton, was performed.

Operation.—The abdomen was opened by a vertical incision through the upper part of the left rectus; a few adhesions were met with. The spleen was then gently brought into the wound, the lienorenal ligaments and gastro-splenic omentum were tied and divided. The pedicle was then transfixed and ligatured in three portions with interlocking ligatures; there was hardly any haemorrhage. The wound was then closed.—(F. D.)

The spleen weighed 1½ lb. Histological examination showed nothing abnormal.

The patient then came under Dr. Humphry's charge, and for a few days after the operation suffered a good deal. So severe an operation was a great trial to a woman disheartened, anxious, and very feeble. She suffered also for some days rather severely from the after-effects of the anaesthetic; the stomach was upset, and food ill tolerated. Not only so, but, as recorded on the charts, the pyrexia, after a promising fall towards normal, became still sharper. Evidently, as the appended blood counts will show, a great commotion was set up in the blood factories. However, on December 28th—as seen in the charts—the pyrexia began to fall, and on January 5th was settling down when another sudden rise took place, coincident with an accumulation in the colon. Notwithstanding, during these weeks the patient was obviously rallying; a little bloom of colour and a little ray of hope brightened her face, and she began in small ways to help herself. And happily this rise of temperature proved to be the last; thenceforward the fever ceased, and on January 24th she was discharged convalescent. For a week she had been sitting up and walking about the ward. Her appearance, if still somewhat anaemic, had greatly improved, and she felt able to return to her home duties.

On the blood counts taken at intervals during her stay in the hospital we need not dwell, as the appended records—all taken by Dr. Dorothy Hare—speak for themselves. The variations are closely in accordance with those displayed in the other published cases. There is an excellent tabulated collection of blood counts in splenic anaemia

Table showing Results of Blood Examinations.

Date.	Haemo- globin.	Red Cell Count per c.mm.	Nucleated Reds Counted per 100 Leucocytes	Total Leucocytes per c.mm.	Differential Leucocyte Counts.						Remarks.
					Poly- morpho- nuclears.	Lympho- cytes, Small and Medium.	Mono- nuclears, Large.	Hyalines	Coarsely Granular Eosino- philes.	Baso- philes.	
1915. Oct. 22	Per cent. 33	2,980,000	0	4,500	Per cent. 72	Per cent. 23	—	2	—	3	Slight poikilocytosis.
Nov. 27	35	2,110,000	0	33,000	—	—	—	—	—	—	Period of irregular pyrexia from Nov. 25 to Dec. 3.
Nov. 30	—	2,630,000	—	11,000	—	—	—	—	—	—	
Dec. 13	■	4,000,000	2	36,000	77	—	23	—	—	—	Dec. 3 operation. Count 10 days after operation. The lymphocytes were chiefly large cells, not distinguish- able from atypical hyalines.
Dec. 18	42	3,850,000	3.5	22,600	69	■	■	3.5	—	0.5	15 days after operation.
Dec. 29	40	4,270,000	1.5	17,200	57	■	■	5.5	■	0.5	25 days after operation.
1916. Jan. 8	42	3,480,000	2	27,600	■	27	3	1.5	0.5	—	31 days after operation. Pyrexia during three pro- vious days.
Jan. 19	■	4,010,000	0	10,000	28.5	55	■	■	■	1.5	47 days after operation.
Jan. 23	—	—	—	—	33	47	13	7	—	—	51 days after operation.

in Thursfield and Gow's paper in *St. Bartholomew's Hospital Reports*, Vol. L, part i.

As our paper is entirely clinical we need not enter into the obscure problems of splenic physiology. Suffice it to say—strange as it may seem—that this large organ, presumably with a function, or functions, so ample, may nevertheless be excised without ultimate, or indeed proximate, impairment of life. After some temporary commotion the body seems to settle down again to work without sensible shortening of its vital capacity. We have not yet data, it is true, to assure us that after splenectomy life may be extended to fullness of years, though some such patients are now under observation whose lives have been prolonged in apparent health for such periods as eight and ten years after the operation; two of Osler's patients have survived for nine and fourteen years (Ede). How this remarkable compensation comes about is variously explained; it is enough for the present to say that our experience is now sufficient to justify us in excising a diseased spleen if symptoms seem to require it.

Dr. Cutlbert Ede (in his M.D. thesis, Cambridge, December 10th, 1915) formulated the following conclusions:

1. No ill results follow removal of the organ; that is, of course, assuming that the operation is performed successfully and under favourable conditions.
2. The first and best marked change in the peripheral blood is an increase in the total number of the polymorphonuclear cells, and a large increase in the number of the red cells. This is instantaneous.
3. During the first year after the operation there is an increase in the absolute number of the lymphocytes.
4. Later these become normal in number, but eosinophiles are increased.
5. Finally the blood picture resumes a perfectly normal state.

Noguchi, quoted by Dr. Ede, comes to the same conclusions, and they are confirmed by our patient's case, and by Captain Jones's case in this JOURNAL, February 5th, 1916. Dr. Ede and others have suggested that in these cases of splenic anaemia the fragility of the reds is increased; to this point Dr. Humphry and Dr. Dorothy Hare gave close attention and care, but reported that in both the cases here mentioned (the boy and the woman) the fragility was not increased—was, in fact, normal.

Another curious point in recovery from splenectomy is that thereby the protective virtues of the body against infection are in no way impaired. (See Fuhs,² and our own case, January 4th to 7th.)

Osler and Rolleston have done much to elucidate and differentiate diseases of the spleen. Splenic anaemia they describe as follows (the quotation is a little abbreviated):

1. Diminution of the number of reds with a falling haemoglobin value per corpuscle.
2. No leucocytosis, usually leucopenia.
3. Enlargement of the spleen, not correlated with any other known splenic disease.
4. The tendency to gastro-intestinal haemorrhage.
5. The termination, if sufficiently prolonged, in hepatic cirrhosis with ascites (Banti's disease).

We are indebted to Dr. Ede for references to published results of operation (excision)—namely, Johnston,⁷ Redman and Willard,⁸ and Sidney Boyd.⁹ The issue of the present series of operations is to show that the advantage of operating in an early and uncomplicated stage of the disease is enormous; the mortality is thus reduced in cases of this class from about 50 to about 10 per cent. Banti's figures are to the same effect. The most perilous event of the operation is that of intestinal haemorrhage, due perhaps to thrombosis of the splenic and other larger veins; but in cases operated upon betimes and under favourable conditions this event also is far less frequent.

It will be seen that our case, both in respect of its issue and of the behaviour of the corpuscles, was conformable with all the chief points of Dr. Ede's experience and that of the authors quoted by him.

NOTES ON TABLE (D. C. H.).

The most interesting feature of the chart is the record of the behaviour of the polymorphonuclears and lymphocytes. Even before the operation their numbers varied widely. The first count showed the leucopenia usually associated with the disease, but later there was a high leucocytosis, coincident with a period of increased irregularity of temperature.

After the operation the variations in the chart followed in the main the usual course. There was an early increase in the polymorphonuclears, succeeded in about six weeks by a sharp rise in the lymphocytes. A high polymorphonuclear count in the fifth week followed a few days of high temperature (January 4th to 7th), which supports the observation of Fuhs that removal of the spleen does not abate the capacity for reaction against infection.

The classification of the lymphocytes and hyalines in the early days after the operation presented some difficulty, and in the first count the large mononuclears are grouped together. Later the types became more distinct, but there still remained at the last examination a large number of these cells intermediate in type.

Before the operation the test for the fragility of the red corpuscles was carried out by Thursfield's method with unwashed corpuscles and gave a normal result. The urine was also tested for the presence of haemolysins and

a positive reaction obtained. The method used was that recently published by McKee (in the JOURNAL, October 23rd, 1915).

P.S.—On February 28th Mrs. K. presented herself again at the hospital for examination. She seemed quite well, and said she felt well. She had done all her housework almost from the date of leaving the hospital. Her tongue, pulse, temperature were all normal; appetite good, bowels regular. Complexion now well coloured, and all the tallowy tint had disappeared. She was strongly urged now to have her mouth attended to and all bad teeth removed from unhealthy gums. Dr. Hare made a fresh blood examination, which is here appended.—C. A.

Blood Examination, February 28th, 1916.

Haemoglobin	48 per cent.
Red blood cells	3,900,000 per c.mm.
White blood cells	41,000 per c.mm.
Differential leucocyte count:		
Polymorphonuclears	48 per cent.
Lymphocytes small and medium...	...	44 per cent.
Large mononuclears	5 per cent.
Hyalines...	1 per cent.
Basophiles	2 per cent.
Nucleated red cells, 1 per cent. of leucocytes counted.

THE PRINCIPLES OF TREATMENT AND THEIR APPLICATION TO WOUNDS.

BY

CHARLES F. M. SAINT, M.D., M.S., F.R.C.S.,

CAPTAIN, R.A.M.C.(T.); SURGICAL SPECIALIST, CASUALTY CLEARING STATION, ON ACTIVE SERVICE; ASSISTANT SURGEON, HOSPITAL FOR SICK CHILDREN, AND SURGICAL REGISTRAR, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

A WOUND is the local effect produced by an irritant on the tissues, and the consideration of irritation should include (1) its cause, (2) its effects, (3) the reaction to it, and (4) its complications.

1. *The cause of irritation* is described as an irritant. Irritants may be classified as (a) non-infective, and (b) infective; in the former class are included mechanical, chemical, electrical, and thermal agents, α rays, etc.; the infective are micro-organisms.

2. *The effects of irritation* are essentially destructive in nature, and they are general (shock) and local (tissue destruction). Whereas one has been accustomed to regard a wound as entailing a breach of surface, ordinarily produced by a mechanical agent, it is more in accordance with reality to include under the term all destruction of tissue, of whatever degree, in whatever situation, and by whatever variety of irritant brought about—for example, contusions, ruptures of viscera, fractures, burns, and injuries of all kinds.

3. *The reaction of the tissues to irritation* consists of vascular changes and cell proliferation (Rutherford Morison), vascular changes predominating in the acute and cell proliferation in the chronic form.

4. *The complications of irritation* result from (a) extension of the process of irritation; (b) superadded irritation; or (c) healing.

PRINCIPLES OF TREATMENT.

The principles of treatment are: (1) Remove the cause; (2) combat the effects; (3) assist the reaction; (4) prevent complications, or deal with them if they have arisen.

1. Removal of the Cause.

A sterile metallic body gives rise to a minimum of irritation sufficient for the production of a fibrous capsule, whereby the body is completely isolated. In a large proportion of cases missiles have come to be regarded as

sterile, particularly rifle bullets presenting a small wound of entry. Under special circumstances, even where the bullet is apparently sterile, it may require removal—for example, when from its position it gives rise to irritation of nerves, interferes with the movements of a joint, etc. Operative measures for the removal of metallic bodies ought to be restricted where α rays are not available. It is unjustifiable, then, to do any extensive dissection, and difficult operations should be postponed till the base is reached. The commonest and most important indication for the removal of bullets, etc., is sepsis in the track. Should operative measures be determined upon, it is essential to bear in mind that too small an incision increases shock from the excessive retraction demanded, and the longer time necessary for the operation.

2. Combating the Effects.

There is general agreement that in the present campaign the degree of shock is greater than might have been anticipated from the nature of the injury, and there seems to be little doubt that it is due especially to excessive mental and nervous strain; in prolonged engagements, also, insufficient food, arising from the difficulty of its transfer, contributes in no small measure. Rough transport following the receipt of the wound, especially in motor ambulances over paved roads, is responsible for a considerable increase in the degree of its severity.

The requirements of the milder cases are met by a good meal, with some tea or cocoa, immediately followed by quiet and sleep. In the more severe cases, rest, with the foot of the stretcher elevated, is essential. Should pain or restlessness be present, morphine must be administered hypodermically. It is remarkable what tolerance to the drug these patients exhibit, half a grain being a regular and not infrequently inadequate dose; it is of advantage as a prophylactic before transporting the patient from one place to another. Stimulants, whether by the mouth or hypodermically, must be given with caution, the rule being "repeated small doses." For example, one tenth of a grain of strychnine will increase the shock (Orile), while one-fifth of that amount given perhaps each hour will benefit the condition. Should the temperature, as is usual, be subnormal, no time must be lost in raising it by the careful application of heat, internally and externally. Lastly, in the worst cases, the chief stand-by is transfusion in one or other of its various forms. The use of saline is the commonest method, and it may be given per rectum, subcutaneously, or intravenously. Of these, the first two are preferable for ordinary use, since absorption takes place according to demand, while the rectal method has this commendation—that sepsis is almost impossible. With most people the intermittent administration of saline per rectum is more successful than the continuous, and it should be given, according to the tolerance of the individual, six to ten ounces every three or four hours. Half an ounce of brandy may be added to the injections, making an average of three ounces for an adult male in twenty-four hours. Auto-transfusion, though useful, is much less in vogue; rectal injection of one pint of hot coffee and half an ounce of sugar is an excellent substitute.

In the treatment of the local condition wounded blood vessels must be dealt with first, as haemorrhage predisposes to both shock and sepsis. Temporarily any of the first aid means may be utilized, while for permanent arrest the method must be chosen according to the case—for example, pad and pressure, forcipressure, ligature, suture or vessel suture, the last being reserved for vessels of some size. The effects of haemorrhage are counteracted ideally by blood transfusion, but, more commonly, saline transfusion, in one or other way already mentioned, is the means resorted to.

The importance of ascertaining that no tourniquet is left on a limb too long (anything above two hours is dangerous) cannot be too strongly emphasized.

3. Assisting the Reaction.

The reaction of the tissues, consisting of vascular changes and cell proliferation, is usually directed against both cause and effects. When dealing with the cause it is called "inflammation," and when dealing with the effects, "repair," but it is essentially similar.

Where open wounds are aseptic the first essential is to close them, but in war wounds do not often fulfil the

necessary conditions, and such treatment is frequently contraindicated by the presence of sepsis.

4. Complications.

Irritation may extend by continuity, contiguity, lymphatics, or blood stream. The mechanical irritants under consideration only produce further mischief by continuity or contiguity, and by the time the patient comes for treatment all the damage likely to occur has been done. Treatment, then, resolves itself into dealing with those complications which have arisen—for example, injuries to vessels, nerves, bones, joints, or viscera, such as brain, lung, liver, gut, etc.

Superadded irritation must be either non-infective or infective, though in warfare they are usually found together. This is especially so in shell wounds, into which portions of clothing, soil, etc., are commonly driven, and these are necessarily infected, calling for early antiseptic dressing of the wounds; as a prophylactic antitetanic serum, 1,500 units administered as soon as possible, has established a well-merited reputation. Antisepsis vaccine, given much less frequently, is likely also to be of value, when the problems of vaccine administration are more completely worked out.

All war wounds must be regarded as septic in greater or lesser degree, and a large number of them contain additional non-infective material as well which must be removed.

Removal of the Irritants.—Keeping in mind the limitations imposed by an absence of *x* rays, three types of mechanical removal are at the surgeon's disposal, the wound being well laid open (1) by forceps or some such other instrument, (2) by irrigation, and (3) by the introduction of hydrogen peroxide, the mechanical agent being the oxygen liberated. No extensive search, especially in the dark, should be made. An extension of this method is advocated by many surgeons—namely, excision of the whole wound, whereby it is hoped to remove all irritants in the tissues forming the walls of the wound. The telephone probe and *x* rays, as accessory to one or other of these methods in the case of metallic irritants, require no comment. Should a mechanical irritant not be removed by one of these methods, it is usually necessary to leave it *in situ* and allow the tissues to deal with it themselves, in which case it is either encapsulated or attempts are made to extrude it, usually through an abscess. The other type of irritant present is infective, the commonest being the ordinary pyogenic cocci, though others are often present, including the *B. coli* and several varieties of anaerobes. These may be removed by the means above described, but, short of excision of the wound surfaces, it is not likely that they will. After the lapse of a few hours excision of the wound is no guarantee that they have been entirely removed, and if all are not removed the opening up of large new surfaces to infection may lead to serious complications. Seeing that these methods are not likely to meet with success in the removal of micro-organisms from wounds, strong antiseptics should be employed as the lesser of two evils. These, in varying degree, act on the organisms present in the tissues of the wound-wall, and hence the method is used as an alternative to that of excision. Pure carbolic acid, from its penetrating antiseptic power, is still the best of these chemical agents, though numerous others are in common use. Hypochlorous acid is at present on trial, and so far results are exceedingly good. The actual canter is an efficient though destructive germicide, and is no longer in vogue.

Assisting the Reaction.—Acute active inflammation is always the reaction to infection with micro-organisms, and its chief function is to deal with the irritant itself. The redness and heat, and in part the swelling and the pain, are due to the increased vascularity present, the chief part of the swelling and pain being due to fluid exudation with increased tension in the part, while the impaired or arrested function is controlled by the pain. The increased metabolism in inflammatory fever is associated with the production of bodies antagonistic to the organisms and their products, while the general impairment of body function, by enforcing rest, provides for a minimal expenditure of energy. Locally the increased vascularity and fluid exudation combat the organisms and their products both chemically and physically, while the impaired function, governed by the pain, produces the rest necessary for a maximal beneficial effect.

Thus we assist the increased metabolism and avoid the evil effects of impaired body function, by keeping the patient in the recumbent posture, keeping up the body strength by easily assimilable liquid nourishment (the thirst indicates the need for fluids), and regulating the excretory action of the lungs by fresh air, the skin by hot bathing, bowels with saline, and kidneys with abundant fluids. Locally, rest and elevation of the part, the application of moist heat, and Bier's bandage or suction glasses, all favour increased blood flow, while hypertonic saline dressings, if they can be borne, assist in marked degree the increased flow of lymph. On the other hand, the avoidance of ill effects of the local reaction is mainly confined to the relief of tension in the tissues by timely incision, and also the provision of efficient drainage, whereby infective material is removed. This includes the evacuation of abscesses, and the careful emptying of all pockets where discharges may be retained.

Incomplete healing may be due to imperfect reaction either to the cause or to its effects, but the commonest cause is superadded infection inadequately combated. Where healing is complete complications are due to the formation of fibrous tissue in the soft parts, with its subsequent contraction, or callus where bony tissues are involved. Treatment is chiefly preventive either by accelerating healing and so diminishing the formation of fibrous tissue, or controlling deformity by careful attention to position, splinting, skin grafting, etc. Should the complications have arisen they must be dealt with according to their nature—for example, adhesions separated, contractures divided, callus removed, etc. The preventive treatment alone is of immediate importance.

TREATMENT OF HEAD INJURIES.

In a clearing hospital it is not possible to watch results unless exceptionally, as the cases are sent out as soon as they can be safely removed. Though I have treated all wounds that have come under my care by the same method, I have only been able to watch throughout their course some of the skull injuries, which have been detained on account of their serious nature. They were treated as follows:

1. The wound was dressed, the lotion used for the removal of the old dressing being 1 in 20 carbolic. Mercury perchloride was contraindicated because iodine had invariably been used lavishly, often producing blistering. If further investigation proved to be necessary, the wound was packed with spirit gauze wrung out of 1 in 3,000 mercury biniodide.
2. An anaesthetic was administered.
3. The head was washed with 1 in 20 carbolic lotion, and the hair shaved off whilst the carbolic was dripped on, following the razor.
4. The bruised edges of the wound were trimmed with mouse-toothed forceps, knife, and scissors, and the wound dried and swabbed throughout (including exposed brain) with pure carbolic acid. In more extensive wounds the excess of carbolic was neutralized by methylated spirit, otherwise it was mopped away.
5. A large flap was reflected, usually with the wound in its centre.
6. The skull was trephined, all loose depressed bone removed, and projecting edges nibbled away. No extensive search was made for distant pieces of bone or foreign body. Bleeding was arrested by fine suture, muscle tissue, or packing.
7. Exposed brain and dura mater were covered with spirit gauze wrung out of 1 in 3,000 mercury biniodide, the free end being pulled through the original wound. A tube was or was not introduced.
8. The operation wound was sutured with silkworm gut.
9. Three days later the gauze was removed; the tube might or might not be removed; if left it was removed at next dressing.
10. Where the original wound resembled an incised wound secondary sutures were inserted on the fifth or sixth day. In punctures this was not necessary, and in extensive laceration and destruction it was not possible.

The number of skull wounds operated upon was 14. Flaps were always sutured up at the time of the operation, and in three cases secondary suture of the original wound

was possible, each time with success. In no case was the wound dressed in less than forty-eight hours. In only one case did sterilization of the track of the projectile as far as the dura mater fail; in this case the sepsis was mild, and was limited to the track, the flap uniting by first intention. There was one death, from meningitis and cerebral abscess, one week after operation; outside the cranial cavity there was no sepsis in this case. In only one patient was there any suggestion of a hernia cerebri. This was in a case with most extensive injury, a large lacerated scalp wound, with marked comminution and depression of skull and extensive laceration and discharge of brain substance. There was also considerable intracranial haemorrhage with pressure symptoms and paralysis of the left arm and face. A large clot was removed at the time of the operation, and subsequently a small protrusion of brain occurred. The protrusion gradually diminished and the face and arm steadily improved. No untoward symptom developed.

NOTES ON WAR SURGERY.

BY

A. MACKENZIE FORBES, MAJOR C.A.M.C.,
A SURGEON TO A GENERAL HOSPITAL IN FRANCE.

ALTHOUGH I cannot speak with any great authority on the subject of the treatment of wounds seen in this war, because the contingent of which I am a member remained on Salisbury Plain until early in 1915, and their medical units were the last to be established in France, yet five months of active surgical service in that country has enabled me to make certain observations which will, I trust, be at least suggestive to some who, like the writer, are placed on "the lines of communication," where atypical rather than typical methods of treatment are necessitated.

In dealing with wounds in hospitals on the lines of communication, the first aim of the surgeon is to save the soldier's life, and the second aim is to save the part affected, the two greatest dangers to both being infection and secondary haemorrhage.

In considering the first it must be realized that the great majority of wounds seen in the hospitals of the lines of communication are infected. Of these infections one sees principally three varieties, which should be considered in order of their ordinary seriousness.

I. Infection by Tetanus.

This fortunately is rare because of the faithful use of antitetanic serum at the front, yet because prophylactic treatment is efficacious, whilst treatment of the incident infection is more rarely so, it is wiser to assume that all our wounded have been infected by tetanus, and that all have not been treated with a prophylactic dose of serum at the front. It may be argued that those who have received antitetanic serum are usually tagged, with an inscription giving the dose administered, when they are received at the hospitals of the lines of communication, but the importance of the wounded being protected against tetanus and the fact that the immunity conferred is probably only temporary makes it wise to consider the administration of a second dose in these hospitals. There is but one danger in this practice, namely, that of anaphylaxis, but this danger may be disregarded, and a dose of 1,500 units of antitetanic serum administered subcutaneously on admission, provided always that the patient has not been so treated at a date earlier than one week previously. In this latter case the antitetanic serum must be administered in a different manner; thus, the dose of this serum must be divided into two parts. The first part, containing 1 c.cm., should be given intravenously. The remaining part should be administered subcutaneously half an hour to an hour later.

Two weeks after this administration of antitetanic serum in the hospitals of the lines of communication the administration of another dose should be considered, and if found necessary it should be given in a divided dose, both intravenously and subcutaneously, as already directed.

II. Infection by Gas-producing Organisms.

These are of the anaerobic variety. Of these, the bacillus of malignant oedema is the most common. More rarely found is the *Bacillus aerogenes capsulatus* (Welch). Infections by these are characterized by their virulence. It is necessary, therefore, to recognize them early, because at first the infection is local, although usually of a deep wound, and practically always of the lower extremity.

A wound so infected is dirty in appearance. It contains pus, or pseudo-pus, with a faecal-like odour, which is similar to liquid faeces in colour and consistency. The parts about it are swollen and congested, but at this stage no characteristic crackling may be elicited by palpating the surrounding tissues; thus it may be difficult to differentiate it from an infection by the colon bacillus. Later there may be localized gangrene around the wound about which crackling can be elicited on careful palpation. In some cases this latter may be noticed without a suggestion of gangrene. The condition at first is really one of cellulitis. The patient's general condition, which is due to toxæmia, is often far worse than is suggested by the local lesion. In those cases where crackling is found on palpation there can be no doubt as to either diagnosis or treatment. In the earliest stages, where there is doubt as to the diagnosis, open freely and drain. Where crackling is found, treat at once as one would a fulminating cellulitis, when the freest incisions and drainage are indicated. At the same time hydrogen dioxide may be injected into the surrounding subcutaneous tissues in an attempt to limit the infection. The infected area must be kept under constant surveillance, always remembering that to save life amputation, in the case of a limb, may be necessitated at any time. When gangrene has appeared, amputation is necessary. This may be done through the emphysematous tissues if the open methods to be described later are employed.

In dealing with infections by gas-forming organisms it is necessary to keep in mind that the patient's life is endangered from the very beginning, and, although very free incisions may relieve the patient even at this date, in cases where we are dealing with a cellulitis alone, in a great number amputation with free drainage will have to be resorted to in the end, in order to save the patient's life.

III. Infections by Staphylococcus, Streptococcus, and Mixed Infections.

These are the more ordinary conditions met with—indeed, are seen in the majority of wounds. They are combated by drainage; often drainage of the most thorough character is necessary, consequently this subject will deserve special study.

It is generally known that, of all wounds, shell wounds require the greatest care. Where there is any possibility of portions of clothing being retained in the wound, cleansing and free drainage must be instituted. If these wounds are superficial, they may often be laid open with advantage. If the wound, on the other hand, is deep and filled with blood clot, this must be cleaned out and care must be taken to tie any bleeding point, but, if none is discovered, such wound will demand special care, as in such not only is secondary haemorrhage to be feared, but concealed haemorrhage may be followed by clot formation and infection. In dealing with all these wounds, primary suture must never be considered, but rather suture to maintain the patency of the wound is often of great advantage. The excision of superficial wounds is advised with the closing of new surfaces, but no wound in which suppuration can be expected is ever closed.

The method of laying open infected wounds by means of sutures, already suggested, is worthy of consideration. Suppose, for instance, a piece of shell is projected under the skin and, more or less, superficial tissues for a distance of some inches. Its track is probably infected, and its surfaces necrosed. It is often found to be wisest to lay such track open, thus converting a tunnel into an open gutter; further, the cleansing of the wound can be hastened by invaginating its edges and sewing them perhaps even several inches from the wound. If this be done it will be found easy to remove these stitches and to bring the edges together when the wound is clean. The same principle is made use of in amputations. In the hospitals of the lines of communication amputations are recommended usually

only when they are necessary to save lives threatened by infection. In the majority of such cases it is unsafe to perform the ordinary classical operations because flaps may harbour infective organisms. Indeed it seems impossible in the majority of cases to procure an aseptic field; thus, often it has seemed wisest to perform simply a circular amputation, cutting through skin, muscle and bone all at the same level, and to leave the wound entirely open. Patients on whom this procedure is adopted are sent to England as soon as possible, where a second operation for the preparation of flaps and the closing of the wound is performed.

These circular amputations are, however, too wasteful, and if it is possible to save flaps, even if they cannot be used at once, it is wisest to do so. Here, then, the method described as "the laying open by means of sutures" is employed. It is my custom to save every portion of skin, fascia, and muscle which it is safe to keep; with these I make flaps at a later date, but at the time of the operation, to save infection, we invaginate them in the same way as a child having torn into vertical strips part of the stem of a dandelion will invaginate these to form a rosette. When invaginated the soft parts are sewn back, as suggested in wounds of muscle and skin. In this way we make a cone-shaped stump instead of a crater-shaped stump, as it appears before invagination. The bone in this amputation should be left as long as possible, because as soon as our cut surfaces are clean we stretch by traction towards the sawn extremity of the bone by means of tape fastened into these soft parts and secured to the distal extremity of the bone. By means of this traction, begun after the flaps are clean, we prevent the contraction of the soft tissues at a time when it is not yet safe to perform the necessary secondary operation of sewing the flaps in their final position.

After the primary operation, when the flaps are sewn back there can be no concealed pockets of pus. In the second stage, whilst the flaps, after cleansing, are being stretched on the bony shaft as a fulcrum, the tissues are under perfect control. It is only in the third stage, when the tissues being clean enough, the soft parts stretched enough, and we attempt the final operation of sawing off the excess of bone and uniting the flaps, that we are called upon to exercise special care for the protection of the limb.

For severe infections of the extremities the bath, or "constant drip," seems the most efficient form of treatment after free incisions have been made.

In the cranium we may have difficulty with infections. Our rule is to excise all wounds perforating the soft parts and before uniting the cut edges to make a careful examination of the skull in order to get some idea of the extent of the injury. Further procedures are only considered in a most conservative way. In a few cases we have endeavoured to prevent infection of an exposed and uninfected dura by placing a thin layer of absorbent cotton over the exposed area and sealing the opening with Horsley's wax. In one patient sterilized paraffin was used. Either dressing may be changed daily.

The laying open of infected wounds has been spoken of not only as a means of preventing collections of pus but of allowing the cleansing of infected surfaces. This latter is often difficult, and yet of the greatest importance in order to minimize the toxin absorbing areas. Recent suggestions point to the use of hypertonic salt solutions in order to secure lymph lavage. Some surgeons still employ the old antiseptic solutions. Possibly the hypertonic solutions show the best results within the first twenty-four to forty-eight hours after operative procedures. The milder antiseptics may have their place in the later days. Undoubtedly, however, the mechanical cleaning of the parts is of greater importance than either. With scissors much can be cleaned. The cautery also is valuable. At the time of Ambroise Paré this was the most reputed surgical instrument. The lapse of time has not detracted from its efficiency. It is not only a decided mechanical antiseptic, but it also causes lymph lavage, without pain subsequent to the actual operation—a point decidedly in its favour.

The saving of limbs in which there are compound fractures with coincident infections demands not only the employment of the means suggested but the most careful immobilization by appliances of such character that it is

possible not only to dress the wounds, but, if necessary, to syringe or irrigate the infected channels. For such in many patients in my service plaster-of-Paris has been used. This dressing, when properly applied, is most satisfactory, especially if it be fenestrated, for drainage, lavage, and dressings. The windows for such purposes, cut in a plaster cast, are carefully swabbed with melted paraffin before each dressing. This is applied over absorbent cotton and fills the interstices between the plaster and skin as well as between the layers of plaster.

Besides all these methods for the treatment of infections, the local as well as the general effect of the sun's rays are often most marked. If it were possible to treat all infected wounds in the open air results would be better than at present, but, unfortunately, this principle, while recognized, has not yet been sufficiently recognized in military hospitals.

Local Treatment.

The local application of general principles is of sufficient importance to suggest the mention of some methods of local treatment which are used in this service.

Fractures about the Shoulder-joint and Upper Third of the Humerus.

For obvious reasons patients reaching a base hospital with compound fractures of these regions rarely show either wound of entrance or exit to be in the outer wall of the axilla, thus the axillary surface is usually most suitable for splinting when there is a fracture of the upper third of the bone. In these fractures, then, we have sometimes employed a triangular splint which can be fashioned in wood by a carpenter in fifteen minutes. One side of this triangle runs from the apex of the axilla to the great trochanter of the femur of the same side; the second side of the triangle supports the patient's extended arm in a position at right angles to the body; the third side simply unites the other two sides of the triangle. Any degree of traction can be used with this splint by the use of adhesive plaster ("stickers") if the supporting arm of the triangular splint has been made long enough. Most wounds can be dressed without disturbing the splint. The position of the third or uniting side of the triangular splint can be changed easily, thus allowing of adduction of the patient's arm when this assures better reposition of the fragments.

Compound Fractures of the Middle and Lower Thirds of the Humerus.

If we are dealing with compound fractures in these regions we often use a small Thomas knee brace, with extension by means of adhesive plaster, as now generally recommended in war surgery. In addition, in this service, we usually fix the fractured ends by means of a plaster-of-Paris collar applied close to the skin and fenestrated at the seat of the wound for dressings, as already described.

Compound Fractures about the Elbow.

These we usually treat in much the same way, because of the necessity of getting drainage, which is facilitated by extension and immobilization made possible by the knee splint combined with the plaster-of-Paris dressing. In very severe fractures about, and implicating, the elbow-joint, it is often safest to excise the whole joint, after which operation a fairly good arm may be expected.

If at all possible, all arms should be saved, no matter how mutilated they may seem at the time of the patient's entry into hospital. Orthopaedic surgery has so advanced in recent years that an arm whose function on the admission of a patient may seem to be irretrievably destroyed may, if saved, by judicious treatment be made into an instrument far superior to the best artificial arm available. The patient when examined may be unable to move his fingers; there may be no function at the wrist. Neither loss is sufficient to condemn the arm. If consistent with safety, we should persist in an endeavour to keep the injured member.

Compound Fractures of the Femur.

Compound fractures of the upper third of the femur are often most difficult to treat; indeed, past experience teaches that many femora so fractured have eventually to be amputated. With the abduction splint recommended by Mr. Robert Jones of Liverpool many of these may be most efficiently treated, yet there are some in whom it is

impossible to irrigate or even dress without moving the thigh if so treated. For these, because immobilization is as important in clearing up the infection as in securing bony union, greater security is demanded. The most difficult form of treatment is often, in this fracture, the most satisfactory in the end; thus the fenestrated plaster-of-Paris spica is recommended. Such a cast, if carefully applied during strong extension and abduction of the leg, if reaching from the nipple to the toes of the injured side, will assure perfect rest and ample opportunity for cleansing the wound by irrigation or the syringe. In such plaster splint the bed-pan may be used and the patient transported any distance in comparative comfort. Plaster-of-Paris will help to save both life and limb, but it must be properly applied by one who is willing to remove it if necessary, thus sacrificing hours of labour if there is any suggestion that some unknown change or affection is taking place underneath the plaster.

In treating fractures of the middle and lower third of the femur, whilst one may in certain cases prefer the use of plaster-of-Paris, the Thomas knee splint is usually a most efficient form of fixation. With this not only may extension and fixation be secured, but the latter may be rendered doubly sure by the coincident use of one of many forms of splints or splinting.

Compound Fractures Implicating and Injuries Penetrating the Knee-joint.

In dealing with injuries to the knee-joint it must be realized that they present one of the most serious problems of surgery. If this joint is penetrated by infective material, and especially if, added to this, there is an injury to either of the great bones forming the joint, life is endangered. Thus treatment of such wounds demands the greatest care. We should here, whilst endeavouring to save the joint, always bear in mind the fact that it is easier to save the limb than the joint. Nearly all serious injuries to the knee-joint are followed by limitation of movement if not by ankylosis. This latter causes the greatest inconvenience. We may well, then, consider whether it is worth while attempting to save a leg in which ankylosis at the knee is the best we can hope for when this attempt to save is made at the risk of the patient's life, and when we know that amputation in the lower third of the femur allows of the use of an artificial limb with a knee-joint far superior to a natural, though ankylosed, knee.

The danger of suppuration in the knee seems to lie mainly in two things—first, the difficulty of drainage, and secondly, the liability of the infection to spread into the synovial pouches and about the intermuscular septa both in the thigh and in the leg. From a mechanical point of view, then, the head of the bed should be elevated in all such cases, in order to minimize the possibility of the spreading of the infection into the thigh, which often means the loss of our means of retreat by amputation through the lower third of the femur in patients in whom our conservative position of watchful waiting has become plainly untenable.

Because of the anatomical conformation of the joint, surrounded as it is by muscle and tendon, and formed by the close apposition of two of the largest bony surfaces of the human frame, drainage depends on the position in which bony apposition is least marked and gravity counts most; thus the outer side of the joint is the position of choice for drainage, and the flexed and strongly abducted and everted position of the thigh and knee is the best attitude of this member during any attempt made to save an infected knee-joint. Other means there are of draining this joint, but my firm belief that an artificial leg, as already suggested, is often better than an ankylosed knee impels me to refrain from describing methods which are indicated only in cases of such gravity that an immovable knee is the best result possible.

Compound Comminuted Fractures below the Knee.

Such fractures can be treated with drainage and almost any form of splint; that used by Mr. Robert Jones of Liverpool—the thin sheet-iron splint covered with boiler-felt—is as good as any, but here again my personal predilection is for plaster-of-Paris.

Compound infected fractures of the ankle can be treated by a variety of splints of a right angle in form. If the astragalus is fractured it is best to excise it.

Compound fractures of the tarsal and metatarsal bones are treated in much the same way as similar conditions of the bones forming the ankle joint. Here conservative surgery again is the most profitable. The injury to a foot must be indeed severe before we are forced to amputate it, and it is only when our line of retreat—in this case a possible amputation through the lower third of the leg—is threatened that we are forced to consider the loss of the foot, provided always life itself is not threatened.

Wounds of the Thorax.

In attending patients with wounds of the thorax we should be willing to "wait and see," interfering only when called upon by the advent of untoward symptoms or conditions.

Wounds of the Abdomen.

For obvious reasons these rarely have to be dealt with on the lines of communication, but in these conservatism should be our motto. Of the few cases we have seen, those in which no operation was performed did best. The hospital nearest the front is the proper place for the treatment of these, and if patients suffering from abdominal injuries are carried there early enough, operations entirely inadvisable in our hospitals further from the firing line can be successfully performed.

In closing this memorandum, based principally on the work of my section in this hospital on the lines of communication, I would accentuate the fact that not only my experience but the experience of others has forged my credo of conservatism as the motto of war surgery.

WORK AT A BASE HOSPITAL.

IMPRESSIONS AFTER SIX MONTHS AS A SURGICAL SPECIALIST.

By W. RANKIN, M.A., M.B., Ch.B.,

SURGEON TO THE OUT-PATIENT DEPARTMENT, WESTERN INFIRMARY, GLASGOW; TO THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW (LATE TEMPORARY LIEUTENANT R.A.M.C., AND SPECIALIST IN OPERATIVE SURGERY AT A STATIONARY HOSPITAL).

Six months spent as a surgical specialist at a base hospital teach one many things—above all, patience. While the variety of cases is infinite in the way of injuries to particular structures, the curious sites from which shrapnel is removed, etc., yet the actual types of operations done are limited, and to one who has had a large experience of emergency work in a busy city such as Glasgow the class of work presents little new or difficult.

Far too little credit has been given to the astonishing healing powers of the fighting man, who, up to the moment of his wounding, is in a state of health much above that of the usual hospital patient, as the result of his open-air life and abundant diet. When this is properly appreciated less will be said about the results of wonderful new antiseptics, and of methods which make the antiseptic era a back number, and of vaccines, etc. Nearly all the cases are septic, and if the work is to be done efficiently, expeditiously, and at a moderate cost, I believe it can best be with a technique in which antiseptics play a large part. A rigorous aseptic technique is a farce in such a type of work, is needlessly expensive, and will not, in my opinion, stand the test of twenty serious operations, packed into twenty-four hours.

Most of my actual operating was done with the assistance of my theatre sister only, though when I required further help I always had willing and able assistants. The procedure in an ordinary case of shrapnel embedded in muscle was as follows: The dressing gowns and towels had been sterilized by steam. The gloves and instruments were boiled, the lotion basin and trays were boiled or flamed out. The gloves were used wet out of sterile water. I scrubbed my hands with soap and water, soaked them for a short time in 1 in 40 carbolic lotion, drew on a pair of gloves, redipped my hands in the lotion basin, and when I had my gown put on I was prepared to start whenever the anaesthetist signified that the patient was ready. I prepared the skin with iodine and fixed the necessary towels with clips. I used the best probe in the world, an index finger, which becomes marvellously educated in seeking out the track of a foreign body through the tissues. I located the piece of shrapnel and removed it with a pair of forceps. I then swabbed out the

track with methylated spirits, made whatever incisions I considered necessary for the relief of the cellulitis, and packed the wound with gauze wrung out of spirits. A dry dressing was then applied and kept in position by strapping or any form of bandage which suited the part best. After the operation I scrubbed the gloves in a special basin, took them off and put them in the sterilizer, where they were reboiled, as was every brush that had been in use. After they had been boiled and put into their proper basins, the instruments went into the sterilizer. I did not change my gown unless it was visibly soiled. I did not wear long-sleeved gowns. The hand-basins which held the carbolic lotion were swilled out, wiped clean of any blood stains, and refilled with lotion. By the time the next patient was under the anaesthetic I was again prepared to begin. This technique was simple: each step was well defined; a brush was boiled, placed in a dish, picked out and used; put after use into a second dish, from this was placed in the sterilizer, and then became ready again for use. Nothing but carelessness could produce a hitch, and it meant a minimum of work to the staff who had lots to do when the rush came. I only lost one case from cellulitis or gas gangrene; in it a piece of shrapnel had tunnelled its way from the thigh to the retroperitoneal space over the brim of the pelvis, and efficient drainage was established too late. It was not always possible to arrange the cases in the degree of their infectivity, but so far as I could judge no case became septic or more septic as the result of coming after a particularly foul case.

Excision of wounds and any perfectly clean case I had satisfied me that my simple routine was quite efficient and therefore, for the type of work, sufficient. The rapidity of healing and the good results made me very slow to change my methods, though there were a few cases in which a variation to some other antiseptic or dressing did benefit. For the most part, carbolic lotion, iodine, and methylated spirits gave most satisfactory results.

Where I failed to find the foreign body I availed myself of the help of x-ray plates. I did not then succeed in every case, but the proportion missed was small.

The incisions I made were always free and were packed with gauze. I did not often use drainage tubing, and never when a vessel of any size was near the track of the wound. In the cases which came from the front with tubing inserted, the track left after its removal was so foul that I avoided its further use. I had no case of secondary haemorrhage of any importance; in the one case which recurred it was easily controlled, and for this happy freedom from an awkward complication I give credit to the free incisions and the gauze packing.

I early recognized that a superficial bullet or shrapnel graze is of the nature of a burn, and that if these apparently trivial wounds are not completely excised, they will remain unhealed for many weeks or months. All such wounds, as well as many other large and small superficial wounds and gutter and tunnelling wounds, were excised without delay. In some cases of wounds of the thigh and the chest wall the wounds after excision were over 12 in. long and had involved muscle. All the big wounds and nearly all the small healed without a stitch abscess, and the excision saved many weeks of painful dressing. At first I used to wash the wounds and mop them with spirit; afterwards I used Colonel Gray's simpler technique—painting the wound and the skin around with a 10 per cent. solution of iodine in rectified spirit before the excision. The excisions which did worst were those over the shin bone.

The line of excision should be in the course of the superficial nerves, not across them. There should be no tension in the sutured wound. Excision should not be performed when there is clear evidence of acute cellulitis round the wound. Multiple punctures and dressing for a few days will allow this to subside, and then excision can safely be performed. Fomentations make the worst possible preliminary dressing, as they cause the area to be soaked in pus.

In every case of scalp wound which came to hospital the wound was excised and the skull beneath examined. The whole scalp should be shaved, since neglect to do this leads to delay and trouble in the theatre, for often it is the unexpected case that has the depressed fracture. No man can by means of a probe correctly diagnose the

extent and seriousness of the scalp wounds made in modern warfare; the wound must be excised, and the condition of the exposed bone examined with the finger and the eye. In this way one learns the number of cases which have fissured and depressed fractures and appreciates why such patients may have headache and other symptoms afterwards. To draft a man with a healed or healing scalp wound to the convalescent camp without having exposed the bone and examined it properly is to court a disaster sooner or later.

The elevation of depressed fractures, the trephining out of small discs where a fracture of the inner plate was suspected, and the evacuation of superficial brain abscesses were common operations; the results were good. Where there was a perforating brain lesion, deep penetration by shrapnel or a bullet, and hernia cerebri, the foreign body was removed when this could be done without danger to life; the further treatment was to apply compresses of alcohol to the exposed brain, but the majority of these patients died. I worked on two principles: (1) to make the skull opening no larger than was really necessary, and (2) to try and do at the first operation all I thought possible for the patient in the way of exploration.

Of the few amputations I did nearly all were partial amputations of hands and of fingers; one amputation only of the foot was done—after astragalectomy had failed to get rid of the infection. I had many cases of infected injuries, to the knee and elbow joints especially, and of compound fractures into these joints, which could have been saved a long convalescence by an early amputation, but free incisions, dressings under anaesthetics, and patience, both on my part and on that of the patients, enabled me to send them home with their limbs in a most satisfactory condition, some with the joints excised, and all glad that they had "stuck it" and happy in the possession of the limb. A run of cases may occur in which primary amputation is clearly indicated, but experience shows that by patience limbs can be saved which lack of judgement would have sacrificed. The surgeon should always consider the question from the point of view of the patient—say two years hence.

For fracture cases I followed the simple methods described in my handbook,¹ and with a good supply on hand of Gooch's splints, of Middeldorp's triangles, and a few long osteotomy and half box splints I was never at a loss to get a patient into a state of comfort. Middeldorp's triangle can be best fitted by means of short slings in place of ties and bandages; this plan was a boon in the cases of compound fractures when the splint required to be readjusted at the dressings. The use of these simple splints properly applied further up the line would save much distress during the train journey. Synovitis of the knee is very frequent, and I was at a loss at first to pick out the cases which would probably do well enough not to be sent home. Latterly I explored all with a fine needle on a good syringe, and in many cases, which gave no history of traumatism, I found the effusion to be blood-stained. These cases were transferred home, whilst the others, with clear effusion and no history suggestive of a loose cartilage or any other derangement, were treated by rest in bed, a Scott's dressing, and a posterior splint from the fold of the buttock to the heel. They usually made a good and rapid recovery, though I have no knowledge of their after-progress.

Many cases of painful and ingrowing toenail were sent to the base. The treatment was avulsion with, when necessary, a Mayo operation. The after-dressing is most important; it should be by a piece of gauze soaked in a 1 per cent. solution of picric acid, and applied moist over the raw surface. It was not removed for five or six days, and then the bed of the nail was invariably found to be healed and hard, so that the patient could be sent to the convalescent camp shortly afterwards.

Some apply wet dressing even after small operations, such as the extraction of a bullet lying superficially. By the time these cases arrived at the base the dressings were simply reeking pus poultices. Useful in a few selected cases no doubt, this form of dressing is absolutely unsuitable as a routine dressing.

The surgeon cannot detach himself from all responsibility for the anaesthetic, but he ought to be relieved as far as possible by being provided with a congenial colleague already an experienced anaesthetist. When a big rush of

work comes the anaesthetist is of more importance than the anaesthetic. Though open ether is my anaesthetic for choice, most of my colleagues had had the training in the giving of chloroform. To all of them I wish to express my thanks for help in many a long day's work. The use of nitrous oxide gas for short and painful dressings proved a great boon. Local anaesthetics and spinal anaesthetics were made use of in selected cases, but neither method is suitable when the staff is small and many cases waiting.

ULCERO-MEMBRANOUS STOMATITIS AND GINGIVITIS AMONG TROOPS ON ACTIVE SERVICE.*

By F. B. BOWMAN, M.B. TORONTO,

CAPTAIN C.A.M.C.; PATHOLOGIST, MOORE BARRACKS CANADIAN MILITARY HOSPITAL, SHORNCLIFFE.

DURING the last few months my attention has been drawn to a freely communicable disease, which, while of a minor nature in so far as it rarely has a fatal issue, is nevertheless of serious import in that it very materially lowers the health and effectiveness of those attacked. I have found it widely prevalent among our troops, more particularly among men returned from the front. Without going into full details, I would here call attention to the symptomatology of the condition, its apparent causation, and what, in my hands, has proved a simple and rapid method of cure. I may state that these observations are based upon the study of more than 100 cases.

Symptoms.

Considerable attention has been given for some years past to pyorrhoea alveolaris, a condition in which small pockets of pus form between the tooth and the gum, so that pressure upon the gum just below where this abuts upon the tooth leads to the discharge of a drop of pus. American observers have shown that this condition is frequently associated with the presence in the pus infiltrating the tissues at the base of the pus pocket of amoebae, somewhat resembling those found in amoebic dysentery, and, like those organisms, acted on specifically by emetine, as demonstrated by Bass. Frequently pyorrhoea alveolaris can be cured by the exhibition of this drug; but not all cases of so-called pyorrhoea alveolaris show themselves equally affected by this treatment.

An examination of cases coming both from the front and from troops in the Shorncliffe area shows that in cases of this condition, both those presenting the amoebae and others in which they could not be found, the most striking feature revealed upon the examination of the smears made from the pus is the presence of what are known as Vincent's organisms in large, not to say preponderating, numbers.

Further study has shown that these same organisms are present in what appear to be excessive numbers in a spreading affection of the gums and the tonsils, which cannot be included under the term "pyorrhoea." Thus, upon the gums (particularly around the last molars), the tongue, mucous surface of the cheeks, and the tonsils (which are most frequently affected), ulcers are to be found. The ulcers tend to spread laterally, save in the tonsils, where they burrow deeply into the tissues. They are covered by a white, friable membrane easily removed, and then leaving a bleeding surface beneath. This membrane is different from that found in diphtheria, which is tough and easily comes away intact. The lesions may suggest syphilis, and indeed Vincent's angina† may be superimposed upon a syphilitic infection of the mouth and throat; but in uncomplicated cases of the condition the Wassermann reaction has always been found negative.

The condition of the mouth in advanced cases strongly suggests scurvy. The gums bleed easily, are injected, retracted from the teeth, and spongy-looking. The teeth

are apt to become loose, and are often tender when tapped by a metallic instrument. In many cases they have become so tender that none but the softest of food can be masticated, and for weeks the men are unable to take the ordinary rations; as a consequence they become seriously run down. The breath becomes extremely fetid, and the patients complain of a foul taste.

There is always more or less glandular enlargement, the submaxillary and sublingual glands being most often affected. Although several authorities speak of a rise of temperature to 105° or higher, in the cases thus far examined from the British troops the temperature has varied between the normal and 102° F. at the highest. Accompanying this constitutional disturbance is lassitude and lack of "go." The most serious constitutional symptom, and one always present when the teeth and gums are affected, is severe depression.

What may be regarded as the acute malignant form of this disease is seen in noma, in which the necrotic tissue shows a dense massing of these organisms of Vincent.

We thus have the following conditions found associated with the presence of masses of the organisms in question:

1. Some (complicated) cases of pyorrhoea alveolaris.
2. Membranous stomatitis and tonsillitis.
3. Noma.

The term "Vincent's angina," in England at least, is generally understood to refer to a particular form of tonsillitis. Ulcero-membranous stomatitis appears thus to be the more satisfactory designation, unless we speak of "Vincent's disease."

The condition is clearly communicable. In our series of cases several were traced to a dentist who had treated a severe gingivitis for pyorrhoea, and the same day also the mouths of three other men; all three had contracted the disease, and were shown by stained smears to be infected with Vincent's organisms. In another case, while the disease had been unknown in two successive battalions that had occupied certain quarters in France, a third battalion using these quarters exhibited no less than 50 cases of the condition. The close association of troops either in camp or in the trenches, and using the same utensils, appears to favour the spread of the condition.

Vincent's Organisms, *Bacillus fusiformis*, and *Spirochaetes*.

If in these cases, by means of a sterile swab, a small portion of membrane or exudate is removed from the mouth and rubbed up in a little warm 0.85 per cent. saline solution on a slide, an examination with a dark-ground illuminator shows in all instances the presence both of spirochaetes and of characteristic fusiform bacilli. Both forms are motile; the fusiform bacillus passes backwards and forwards with a tumbling motion, and not steadily as is the case with the flagellate bacilli, such as *B. typhosus* and *E. coli*. If smears be made and stained, the clearest picture of these organisms is given by Giemsa's stain. Successful results are obtained with plain methylene blue or Loeffler's solution, which show the fusiform bacillus and the spirochaetes distinctly. The bacilli are not stained evenly, but are usually barred, with an occasional granule deeply stained situated anywhere in the organism. The bacillary forms are from 12 to 15 μ long, and vary in width from 1 to 5 μ . The spirochaetes are very slender and delicate organisms. The number of convolutions varies from 5 to 12, the usual number is 9. No membrane can be seen. In stained smears these spirochaetes have no definite relation to the fusiform bacilli present in the same specimen; they are found sometimes in large bundles, sometimes singly.

This Vincent's spirochaete can usually be distinguished from *Spirochaeta dentium*, which has commonly no more than five convolutions, and from the *Treponema pallidum* of syphilis, which has between five and twenty-five, and also stains faintly and with difficulty. *Spirochaeta refringens* (a form not uncommon in the mouth) is much coarser and has broad sections.

The organism has been cultivated by Tunncliffe, who states that she was able to obtain distinct transition from the bacillary to the spirochaetal form. We have obtained cultures by taking some of the exudate upon a sterile swab and rubbing this up with hydrocele or ascitic fluid, and inoculating the emulsion into a deep tube of peptone broth,

* The fuller paper, of which this is an abstract, will appear in the Proceedings of the Royal Society of Medicine, Medical Section.

† So called after Vincent, the French bacteriologist, who clearly laid down (in 1898 and 1905) the relation between these organisms and ulcero-membranous tonsillitis and stomatitis.

into which has been dropped a small piece of sterile kidney or liver from a rabbit. The tube is closed by a sterile rubber stopper which has passing through it a capillary tube. The tube is filled quite full of the medium, and on pushing in the stopper this rises into the capillary, which is immediately sealed off, thus affording a strictly anaërobic culture medium. At 37° C. the growth appears in a few days as a faint cloud above the sterile tissue in the tube. Usually this affords a great preponderance of fusiform bacilli; a very foul odour is given off from the medium, closely resembling that exhaled from the mouths of those affected. Starch-ascitic fluid cultures, prepared according to Rosenow's method of deep tubes, are also successful. In fact any ordinary culture medium containing serum or ascitic fluid will afford growths of the organisms under anaërobic conditions.

Thus far inoculations into the lower animals have been wholly unsuccessful in reproducing the disease, and so not only is the question of the identity of the two organisms still undecided, but also, as Koch's postulates have not been fulfilled, we lack the crucial demonstration that these organisms are the essential cause of the conditions here described. This much, however, is to be noted—that they are present locally in enormous number in all the conditions here described, and that with the disappearance of these organisms the conditions undergo healing. This last fact alone may be taken as adequate proof that if they are not the only, they certainly are an essential factor in the causation of these states.

Treatment.

In pyorrhoea alveolaris, where the amoeba is demonstrable, local treatment with emetine, as already noted, frequently brings about cure, but emetine is of no value in the more widespread conditions of ulcero-membranous stomatitis and gingivitis and Vincent's angina. For these conditions many forms of treatment have been recommended. Trichloro-acetic acid, carbolic acid, silver nitrate, iodine, and hydrogen peroxide have all been used with some success. As a spirochaete is present, arsenic in some form, from its well-known effect upon spirochaetes, would appear to be the ideal application. Of all arsenical compounds salvarsan is the least toxic, and, as a matter of fact, salvarsan has a marked effect upon the condition, even if used merely as a mouth wash, and would thus seem to be indicated. Its use among troops, however, is prohibited, both from its cost and on account of the instability of its solutions. This close association between pyorrhoea, with its amoebae, and ulcero-membranous stomatitis, suggested a combination of ipecacuanha or its alkaloid and Fowler's solution. These are compatible, and the following treatment has been found to have remarkably rapid and favourable results.

Vinum ipecacuanhae...	3 ss
Glycerinum	5j
Liquor arsenicalis	ad 3j

M.; fiat mist. Sig.: To be used as a mouth wash; do not swallow. Label "Poison."

Where the gums only are affected the solution can be carefully applied to the gums and pockets around the teeth, after cleansing away the pus. A small applicator should be used. Where there is ulceration elsewhere in the mouth or throat, the ulcer should be thoroughly wiped out twice every day with the above solution. All patients, whether or not the gums be infected, are instructed to drop ten or fifteen drops of the mixture on to a tooth-brush twice a day and to brush the teeth and gums vigorously.

Employing this treatment the condition clears up with remarkable rapidity. Even in advanced cases, in my experience, the alteration in the state of the mouth is obvious in three days. The ulcers are seen to be healing; the foul odour of the breath disappears; the teeth cease to be tender. The general depression clears up, and within a week patients who before treatment could not masticate solid food, can eat such food without discomfort and with enjoyment. Swabs from the affected areas now no longer yield the fusiform bacilli and spirochaetes.

The diagnosis and treatment are both so simple and the results obtained thus far so satisfactory that I can confidently direct the attention of medical officers in charge of troops to the existence of this condition and to this

means of bringing about cure. I shall be grateful if they will give me information of each case under the following heads:

(1) Name. (2) Unit. (3) Regimental number. (4) Date (approximate) of onset of disease. (5) Date when first examined. (6) Location of trouble. (7) Symptoms, local and constitutional. (8) Results of treatment.

MEDICAL, SURGICAL, OBSTETRICAL.

TRENCH FOOT AT HOME.

"POOR MAN'S GOUT" and "podagra" are complaints the conditions of which might be reconsidered beside those of trench foot. Here is a man with a swollen and a painful foot who has had abundant colchicum in the last three weeks, with little or no advantage. His past inebriety he admits, and he has had rheumatic affections before. A scrutiny of his leg, however, reveals the cicatrix of an injury of forty years ago, when the leg was broken, and it is legitimate to infer that nervous and circulatory functions in the limb are still obnoxious to that old injury. What recent happenings have been brought to bear? The patient has the explanation: He had been working on concrete and in cold and wet; the men had asked for big boots to protect themselves, but none were provided. In the case of this patient his sound leg had withstood the exposure; his weaker leg and foot had suffered; hence the pain, the oedema, and the other symptoms, which we call gout.

Those who look narrowly into the ways of the workman will be able to find an excuse, here and there, for his alcoholic habits. Hugh Millar has said that his fellow masons washed down the dust of their trade with deep draughts of ale. The miner, who turns to drink when he has left the shaft, wants something to counter the mephitic effect of carbon monoxide; and in many another case the inebriety of the labourer may plead the unmitigated rigours of his toil. My particular desire at the moment is not an exacter pathology of gout, but a sympathetic interest in any of its determinants in industrial life. Wellington boots, indeed, and rubber boots in the trenches; and for those who are working at home a proper equipment, too. The tools of the workman have from of old been put beyond the clutches of the creditor (Deut. xxiv, 6), but a greater loss to the workman is the power to use them; and so far as arthritis, in any form, is an industrial disease, its prevention is required.

Bristol.

DAVID A. ALEXANDER, M.B., Ch.B.

THE CONTROL OF "DIPHTHERIA BACILLUS CARRYING."

RECENT papers in the BRITISH MEDICAL JOURNAL on diphtheria carriers prompts me to describe a simple method of ridding a carrier of the diphtheria bacillus.

I employed it in an outbreak of diphtheria which occurred recently at a military hospital in the Malta command. Eight carriers were discovered bacteriologically by Mr. Mitchell (sanitary officer of the hospital) and Captain Crofton (bacteriological specialist). The throats and noses were cleaned with gargles and douches of potassium permanganate. As the carriers did not seem to decrease, further measures were adopted.

In Peking I meet a good many cases of acute follicular tonsillitis, and, as the Chinese demand quick cures, I have been accustomed to paint the tonsils with 50 per cent. silver nitrate, whilst I have painted several of my colleagues' throats with 90 per cent. silver nitrate. One application of the latter and two of the former suffice to cure the tonsillitis clinically. I adopted this method in the diphtheria carriers. The pharynx, tonsils, and posterior nares were cocaineized with 20 per cent. cocaine hydrochloride, using a forehead mirror, and these parts were then painted with 50 per cent. silver nitrate. The nostrils were plugged with gauze, soaked in 1 in 10 ichthyol in glycerine, the latter being the dressing I have found useful in ozaena, which is not uncommon in China, and as a dressing after submucous resection of the septum, done in the presence of ethmoidal suppuration. Swabs were

taken from the nose and pharynx before and after this treatment by Mr. Mitchell and examined bacteriologically by Captain Crofton. The positive swabs proved to be negative after two applications of this treatment.

Extreme care should be adopted in the application of the silver nitrate, otherwise severe spasm of the glottis is caused; the application must also be thoroughly done—that is, the posterior nares and tonsils and pharynx must be painted. By using this method the hospital was freed from the diphtheria carriers and reopened.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

The Heart in School Children.

At the second meeting of the session, held at Stafford on February 24th, 1916, the President, Dr. F. M. ROWLAND, was in the chair, and Mr. PRIESTLEY read a paper on heart disease in elementary school children, which was based on a study of Staffordshire children. Diagnosis of heart disease in elementary school children examined at school inspections was, he said, difficult, owing to the fact that in a large proportion of the cases neither the children nor their parents or teachers made any complaints of discomfort, or only the most trivial and ambiguous ones. Diagnosis had to be based on cardiac symptomatology almost entirely. When care was taken to note every deviation from the normal signs or sounds of the heart, it was found that at least 40 per cent. of all school children exhibited them. Most of them were obviously trivial, but 7 to 10 per cent. of all school children exhibited them in a degree worthy of a special note. The larger part of these well-marked cases were haemic or functional, and not, so far as could be ascertained, associated with any gross permanent lesions of the heart. When these functional cases were eliminated by a critical and conservative scrutiny, not passing as organic any case that might possibly be merely functional, there was left about 1 per cent. of all school children suffering from "organic valvular" disease. Among the functional cases were examples of dilatation unaccompanied by any signs of organic disease. Some of them were due apparently to cardiac atony, others probably to transient toxæmias. Something over $\frac{1}{2}$ per cent. of all school children showed functional dilatation. Of 676 cases of undoubted organic disease the various valves affected were: Mitral regurgitant 83.1 per cent., mitral stenotic 4 per cent., mitral regurgitant and stenotic 7.3 per cent., tricuspid 0.7 per cent., pulmonary 3.9 per cent., aortic 1 per cent. Of 622 children with organic heart disease observed over several years, 344 (55 per cent.) never at any time complained of any symptom that could be ascribed to the heart. The following analysis was given of the 278 (45 per cent.) who had discomfort at one time or another: Malaise only 145, cyanosis 57, dyspnoea 50, pain over heart 30, headache 20, fainting attacks 17, oedema 8, palpitation 4, sickness 3, sleeplessness 2, clubbed fingers 2, catarrh possibly due to venous stasis 2, heart failure and loss of compensation 2, epistaxis 1, cough on exertion 1, giddiness 1. There was a little overlapping in this classification, the same child in a few instances having more than one cause of complaint. In the non-complaining group there were examples of every sort of valvular lesion, congenital or acquired.

Some After-Histories.

Dr. COOKSON, in continuation of a paper read at the meeting held in February, 1913, on two cases of women of 28 recently operated on for carcinoma, gave an account of the further history of the cases.

1. Mrs. B., first operated on on January 22nd, 1913, for intestinal obstruction of unknown origin. Median incision; carcinoma of sigmoid found; colotomy performed. On January 27th sigmoid removed and end-to-end anastomosis performed. Six months pregnant at time; miscarried on

February 1st. Went home very well on February 19th, 1913. She remained very well until beginning of November, 1913, but only saw her doctor on November 19th, who asked me to see her on 20th. No trouble with bowels, but had a hard nodulated mass in left iliac region. November 28th, 1913, operation. Nodule of growth found in abdominal wall, fluid in pelvis, and mass a large secondary growth in left ovary. Growth in abdominal wall removed and left ovary. The anastomosis site could only be defined by the scar in the meso-sigmoid, but there was a small plaque-like growth in the wall where the ovary touched bowel, and a small growth in the uterus. Owing to increasing pain I operated again on December 29th. Everything was so matted together then that I could only do a colotomy. During succeeding months pain became gradually worse, and at one time she took as much as 12 grains of morphine in pill a day, but still did her housework and even bicycled up to October, 1914. In November she took to her bed; vomiting frequent, face and legs swelled, growth involved the colotomy opening. She had haemorrhage from rectum. Practically took nothing but water and had complete obstruction for a month, dying on December 25th, 1914.

2. Mrs. R., cauliflower growth of cervix uteri. After some preliminary treatment, Wertheim's operation performed on January 6th, 1913. Wound broke down and had suppuration in pelvis, but recovered satisfactorily, and went home very well on February 19th, 1913. Heard occasionally that she was keeping very well, but on December 21st her doctor asked me to see her, and I found her dying. It was not possible to examine her satisfactorily, but there was no growth to be felt from the remains of the vagina. She was very distended and evidently dying of general peritonitis. The history was that she had had a temperature for a fortnight up to 103° at night, normal or subnormal in morning; that there had been a lump in the right iliac region, which had softened; and that the vomiting and distension had followed. It seems probable that this was a septic condition, and not due to recurrence.

Dr. Cookson also mentioned two other cases of early carcinoma, one because the patient was the same age as these two, the other because of the extremely early age for carcinoma of rectum.

Mrs. P., aged 28. A lump in left breast doubtful in nature removed first; pathological report, carcinoma. Radical operation performed August 31st, 1911; patient still free of recurrence.

Mr. H., aged 16, seen in consultation on January 26th, 1916; 6 ft. 1 in. in height, complaining of gradually increasing weakness, loss of appetite and flesh. Always from a small child subject to looseness of bowels, but for some eleven weeks the stools had been tarry, and he had had attacks of vomiting. Through the abdomen masses of faeces could be felt along the greater part of the course of the large intestine, and per rectum some 3 or 4 in. from the anus a growth, nodular, bleeding readily, affecting the whole circumference of the bowel and fixed to the sacrum and other parts. I did a colotomy, but he died eight days later unrelieved.

Reports of Societies.

DISCUSSION ON WAR INJURIES OF JAWS AND FACE.

At the meeting of the Odontological Section of the Royal Society of Medicine on February 28th, the President, Mr. H. BALDWIN, in introducing this discussion, referred to the admirable organization of special dental treatment which he and some English colleagues had seen when visiting France lately. He thanked most sincerely the French and American dentists for their contributions to the exhibition and discussion. He urged the establishment of special hospitals in each command of the United Kingdom to deal with injuries of the jaws, and of a competent officer on the staff of the Director-General to advise on dental matters. Two fellows of the section were now serving as lieutenant-colonels in the R.A.M.C., and were fit men for such a post. Skilled dental aid should be called in at the earliest possible moment. The details of the making and adjustment of the necessary splints were obviously outside the sphere of the general surgeon, and could only be dealt with by the trained dental surgeon.

Mr. LEWIN PAYNE showed a series of slides and models illustrating his personal experiences. His conclusions were: (1) That nearly all jaw injuries require dental aid. (2) That dental treatment should be commenced early. (3) That the dental surgeon employed should be one already familiar with the details of treatment. (4) That these cases should be segregated.

Dr. HAYES, of the American Dental Ambulance in France, said there were twenty-nine centres of special dental aid in France. Cases were, however, often left too long in a general hospital. Cases at the special dental centres were often rightly allowed to remain in France on account of the very specialized nature of the treatment. The dental surgeon at the front should be equipped to make splints for immediate fixation. He emphasized the point of early dental treatment. They had treated 380 cases, of which 30 were shown by photographs in the exhibition.

Dr. HOTZ, of Paris, also dwelt on the evil following delay in calling in dental aid. In some of his cases there was practically no access to the mouth when he first saw the patient. Often only an intra-oral splint was needed, but only a dentist could make it. He made all his splints in vulcanite.

Mr. J. F. COLYER spoke of his experience at the Croydon Military Hospital, where there were 200 beds for jaw injuries and at present 130 cases. In dealing with ununited fracture of the mandible he had obtained excellent results by extracting the tooth on either side of the line of fracture; some of the cases were six to twelve months o.d. Where there was only a small loss of bone he had obtained bony union by extracting the molars of the smaller posterior fragment, and if necessary their opponents, thus allowing the posterior fragment to be tilted up by muscular action and come into contact corner-wise with the anterior fragment. He preferred good bony union in such cases to exact dental occlusion. Before fixing a splint he removed all sources of sepsis. An outside splint gave comfort by resting the part. He had instituted a dietetic course, beginning with fluids and gradually hardening, to teach the patients to eat. Bringing together those similarly afflicted had been a source of great comfort to many who had found life intolerable when alone in their misery.

Sir FREDERIC EVE had used phosphor-bronze wire to stay the fragments apart in a case of resection for fibrosarcoma. Some twelve years later they were embedded in fibrous tissue. He had used bone grafts taken from the rib in two cases and these seemed to be successful. The periosteum was stripped off. He did not think plating advisable in cases of gunshot wounds. Wiring or splints were better.

The discussion was resumed on March 6th, when Mr. W. HERN showed slides and models of cases under his care. He had found simple wire splints most useful. He spoke of the good results of drawing the centre fragment forward and fixing it to the maxilla in cases of double fracture of the mandible. In these cases the centre fragment was displaced backwards and downwards.

Mr. HOPSON said that he had seen salivation follow the use of ungilded German silver splints. He showed a case of bone-grafting described below.

Mr. S. P. MUMFERY thought that in cases in which loss of bone did not exceed $\frac{1}{2}$ in. in the mandible, the fracture might be put up in good occlusion with a reasonable hope of bony union. Where contraction and approximation of fragments had already occurred slow separation might be followed by stretching of the osteogenetic tissue.

Mr. NORTHCROFT had used intermaxillary traction to remedy displacement when teeth were absent in one fragment of the mandible. He showed a useful "open" metal splint designed to allow of easy inspection of the teeth when replacing the fragments.

Mr. NORMAN BENNETT said that he used no fixed caps or splints. He found he could not fix them on account of the cement getting washed out before it set. He used gradual methods and, where there was not much loss of bone, allowed the parts to consolidate a little before separating them.

Mr. W. W. JAMES recommended rubber tubing tied by its ends into a bow and placed inside the lips to distend cicatricial parts. Great relief might thus be given to dribbling.

Mr. PEARCE did not like Mr. Colyer's idea of extracting in cases of delayed union. He thought patience would preserve the teeth. He spoke of the wonderful reception given by French dentists to those British dentists who had visited France.

Mr. J. G. TURNER suggested that in cases in which loss

of bone was not too extensive pieces of bone might be loosened from the patient's own mandible and turned into the gap while still retaining a vital periosteal connexion with the bone. Where there was small loss of bone the histories of several cases showed the possibility of regeneration of new bone if the parts were immobilized in a position such as to preserve the gap. X rays showed that this was effected by fragments of osteogenetic tissue scattered in the wound. When the parts had fallen together he advocated waiting a little and then stretching slowly to stretch the new-forming bone.

Among cases shown were three of bone-grafting, one by the American Ambulance of a year's standing, and two of later date—one by Sir F. Eve and Mr. J. F. Colyer, and one by Sir A. Fripp and Mr. Hopson. All seemed to be successful. In Sir A. Fripp's case $2\frac{1}{2}$ in. of the rib had been inserted and a splint bridge was worn on the teeth; x rays showed bony union at one end at least. The exhibition was visited continuously during the two weeks it was on view. The splints alone demonstrate the need of special dental aid.

Dr. Pont's lucid type-written description of his cases was widely read. Members of the Odontological Section are unanimous in expressing their admiration of the work of their French and American colleagues, and their appreciation of the part they played in promoting a unique exhibition and discussion.

Reviews.

MORPHOLOGY AND ANTHROPOLOGY.

THE second edition of Dr. DUCKWORTH'S *Morphology and Anthropology*¹ is in course of publication in a new and greatly extended form. The first volume now before us corresponds to section A of the previous work. It deals with the anatomy of the mammals, especially of the primates, and we understand that other volumes dealing with embryology, craniometry, and palaeontology, will be published after the termination of the war. After a short introduction to the mammalia and the orders into which that group is divided by modern systematists, Dr. Duckworth passes to a full account of the primates, first reviewing the taxonomy of the group, though without referring to Dr. Elliot's rather revolutionary "Review of the Primates." He then deals at length with the external and internal anatomy of several of its members, especially a lemur, the tarsier, an old world monkey, and the gorilla. The crania and the teeth of the primates are described in the concluding chapters.

The book is written primarily for students of physical anthropology, and presumes the very special knowledge of anatomy which is only possessed by the few who have passed through the human anatomy schools. The book, in fact, is "advanced," and the ordinary zoologist will find himself once more cut off from understanding the thoughts of the anthropologist, which is to be regretted, because anthropology tends to isolation and specialization, even though it is so many-sided. All biologists will notice with pleasure Dr. Duckworth's insistence on the fact that specialized and simple types hardly exist in real life; he never lets us forget that extreme specialization in one organ is very often found in a creature which is in other respects simple, or even degenerate.

One of the most satisfactory parts of the book is that which deals with the dentition of the primates; it might interest equally a zoologist or a dentist. The origin of cusped teeth has always presented great difficulties to vertebrate morphologists, and Dr. Duckworth gives a summary, we believe the only one, of the theories which have been put forward from time to time by Cope and Osborne, Marett Tims, and others. It is very lucid, and also, we believe, very fair, but it is disappointing that more space could not have been spared for it; the author would have done well to give more definite indications as to which of all the views he himself supports, and to what extent any of them have been accepted by workers

¹ *Morphology and Anthropology*. By W. L. H. Duckworth, M.A., M.D., Sc.D. Second edition, vol. 1. Cambridge: The University Press, 1915. (Med 8vo, pp. 318; 208 figures. 10s. 6d. net.)

among the other mammalia. The array of facts is immense; they are arranged logically, and it is well to have them in this accessible form, but some will wish that the author had embodied among them a passing word of generalization, even though his summary has yet to appear.

The illustrations, many of them from the author's own line drawings, are very clear. The indexes are unfortunately quite inadequate.

CAUSES OF VIOLENT DEATH.

In his thesis for the degree of M.D. in State Medicine at the University of London, entitled *An Inquiry into the Statistics of Deaths from Violence and Unnatural Causes in the United Kingdom*,² Dr. W. A. BREND has examined the official statistics in twelve blue-books and reports issued by the Home Office, the Registrars-General for England, Scotland, and Ireland, the Local Government Board, the Board of Trade, and the London County Council. He shows that the present system of collecting and recording information concerning such deaths is far from satisfactory, and that this is in part due to inco-ordination and differences in the system of classification, nomenclature, area covered, and other particulars as adopted by the various authorities. Particular attention is drawn to the waste of the valuable source of information which might be afforded by the records of the various coroners; they are claimed as the private property of the coroners and are not made use of except for a brief summary of verdicts issued by the Home Office and a special report on deaths from starvation published by the Local Government Board. In criticizing the figures given under the heading "Murder," as returned by the Home Office and the Registrar-General, the author calculated that it would appear as though 60 per cent. of the murders committed in this country remain undetected, but concludes that this inference is not justified in the absence of knowledge as to how far the figures include cases which are not criminal at all, according to the decisions of the higher courts. It is not clear whether these figures include cases of infanticide in which a verdict of "murder against some person or persons unknown" is returned. The number of such cases is by no means negligible. In dealing with "deaths from overlying" Dr. Brend emphasizes, perhaps too much, the importance of having the body examined after death by expert pathologists to exclude natural causes of death, but the recognition of acute capillary bronchitis, gastric disturbances leading to convulsions, pyelitis and even bronchopneumonia is certainly not always easy. Attention is drawn to the marked seasonal variation in the number of deaths from overlying and to the difference in their number in rural as compared with urban districts, amounting to nearly 40 per cent. in favour of the former in spite of the fact that the difference in overcrowding is only 11 per cent. A possible explanation, which the author does not mention, may be found in the practice which working-class parents make, especially over the week end in large cities, of taking their infants out till late at night while they do their weekly shopping. This practice would expose infants to the risk of natural disease, especially in the winter months, and though coroners do not now notice an excess of these deaths on Saturday night it is possible that many are to be attributed directly or indirectly to this habit.

Dr. Brend's thesis covers a wide range, from "murder" to "deaths under anaesthetics." It is of considerable interest, and he has certainly made out a case "for believing that in certain forms of death from violent and unnatural causes we have a field for investigation and an opportunity for saving human life which has hitherto been relatively neglected."

MENTALLY DEFECTIVE CHILDREN.

At the present time, when as yet the powers and duties conferred on local authorities and education committees by the Mental Deficiency Act, 1913, are a matter of much consideration and the policy to be pursued of much un-

certainty, *Mentally Defective Children*,³ a translation of BINET and SIMON's little book, is very welcome. The names of the authors have become very familiar in connexion with the scheme of tests they devised for measuring the level of intelligence, but few are acquainted with the splendid work carried out by them, and recorded in the volumes of *L'Année psychologique* and in the present book, which led up to and formed the foundation of this scheme. In Dr. DRUMMOND's admirable translation the first origins are seen of the idea which was ultimately worked out with such thoroughness, and it was a happy idea to include as an appendix the actual tests to which the work ultimately led; the schedule of tests has been translated by Miss Margaret Drummond, who has added general directions regarding their application.

The book was specially intended as a guide to the admission of mentally deficient children to special schools or classes. The preliminary steps are to describe the mental and moral characteristics of such children, and form a theory as to their real nature. The problem is attacked partly by the method of questionnaire and partly by direct observation, and the theory on which their general conclusions are based is that the defective child does not resemble in any way a normal one whose development has been retarded or arrested, but that his specific characteristic is an unequal and imperfect development. It may surprise some of the critics, and even some of the admirers of the Scale of Intelligence Scheme, to learn, or to be reminded, that this was the view held by Binet; much that has been written about his scale has failed to recognize the purpose for which it was devised and the limited claims made by its authors. It was their dislike of empiricism and vague generalities and *a priori* conceptions that forced them to devise questions and tests, to analyse the result of their applications in different cases, and gradually to systematize their method and the information so obtained.

A chapter on the medical examination of defectives raises interesting questions, and answers them, perhaps, not quite in accordance with medical views in the past, and yet, it must be admitted, with good reasons adduced. A further chapter discusses the methods of education from the practical point of view that all instruction given to defectives should be subordinated to their mode of life. The spirit of the book and its value, whether to science or to the cause of educational and social reform, is well summed up in the concluding sentence: "The essential thing is for all the world to understand that empiricism has had its day, and that methods of scientific precision must be introduced into all educational work, to carry everywhere good sense and light."

THE AGE OF THE EARTH.

PROFESSOR JOLY's book, *The Birth-time of the World*,⁴ contains twelve essays written at various times during the last quarter of a century. Like Tyndall, the professor has been drawn to write about the Alps, and the many thoughts concerning the problems of life, time, and eternity raised in the mind of the traveller in Switzerland. As a geologist, Professor Joly sees in the Alps a writing-block for Time, and is prompted to attempt an estimate of the age of the earth from the geological data of subaerial denudation, comparing the result with other estimates based on astronomical data and the calculations of our experts in radium. The method is that employed many decades ago by proficients in other branches of physical science, notably by James Croll. Professor Joly has the advantage of fuller information, and makes a most interesting story of it all. As a mere visitor to the summer pastures of the Alps, he has been struck—as who has not?—by the richness of the flora there burgeoning, and he gives excellent photographs of his own taking to illustrate many of the points raised in these essays. Another subject that he deals with is skating, and he shows that the possibility of this method of progression depends on the lowering of the freezing point of

² *An Inquiry into the Statistics of Deaths from Violence and Unnatural Causes in the United Kingdom*. By W. A. Brend, M.A. Camb., M.D., B.Sc. Lond., of the Inner Temple, Barrister-at-Law. London: C. Griffin and Co., Ltd. 1915. (Demy 8vo, pp. 80. 3s. 6d. net.)

³ *Mentally Defective Children*. By A. Binet and Th. Simon, M.D. Authorized translation by W. B. Drummond, M.B., C.M., F.R.C.P. Edin. With an Appendix containing the Binet-Simon Tests of Intelligence by Margaret Drummond, M.A., and an Introduction by Professor A. Darroch. London: E. Arnold. 1914. (Cr. 8vo, pp. 189; 13 figures. 2s. 6d. net.)

⁴ *The Birth-time of the World, and other Scientific Essays*. By J. Joly, M.A., Sc.D., F.R.S. London: T. Fisher Unwin, Limited. 1915. (Med. 8vo, pp. 321; 38 plates. 10s. 6d. net.)

water by pressure; with the result that it may truly be said that the skater skates on water, not on ice. Other essays are entitled "Other Minds than Ours?" a discussion on the alleged inhabitation of Mars; "The Latent Image," an address to photographers; "Pleochroic Halos" and their connexion with radio-activity, a matter for crystallographers and mineralogists; "The Use of Radium in Medicine," a lecture to post-graduate students of medicine at the founding of the Dublin Radium Institute last year; the last essay in the book is "A Speculation as to a Prematerial Universe," a metaphysical exposition. Professor Joly writes in an interesting manner, and we may commend his volume to general readers with the assurance that they will find in it something to arrest their attention.

NOTES ON BOOKS.

Appleton's Medical Dictionary,⁵ a new work with an editor, an assistant editor, and seven special contributing editors, is designed for the use of medical men. It has an appendix with notes on the preparation of pathological specimens, diets, certificates of births and deaths, reciprocity among the North American States, and cases of poisoning. The book is clearly printed, but contains numerous misprints, particularly in the chemical formulae it gives. Certain terms of little utility are given, such as "Kupiology, the pathology of malignant ulcers," and "Hematoncus, a name for several varieties of angioma." Certain common terms are absent, such as "streptotrichosis," "emunctory," "proteid." The chemical term "aryl" is inserted, while "acyl," an equally common term, is omitted. "Pituitrin" is misspelled "pituitin." "Erlenmeyer" is set down on p. 894 as "Ehrlemeyer." Throughout the dictionary American spelling is employed. Medical men nowadays are already supplied with an abundance of excellent medical dictionaries, each with some special excellence in its own department. Gould's *Illustrated Dictionary of Medicine* is very large and complete, and his *Pocket Medical Dictionary* is small and complete. Dorland's two *Medical Dictionaries*—the larger illustrated, the smaller of pocket size—are both very compact and full. Hobblyn's *Dictionary of Terms used in Medicine* is familiar to medical men of many generations in this country. It would appear, therefore, that a new medical dictionary must force its way upon a rather crowded stage, and, unless of exceptional merit, can hardly expect to find a leading part unapportioned.

The eighth edition of DORLAND'S *Illustrated Medical Dictionary*⁶ follows two years after the appearance of the seventh edition. The text has increased by thirty pages; nine of these are occupied by new clinical and laboratory tests. So far as the point can be determined by a cursory examination, Dr. Dorland seems to have brought the dictionary well up to date, and to have done his work well. The book will be found very useful by students and practitioners of medicine. As is perhaps natural, the illustrations are the least satisfactory part of the book.

As a book of comfort for those whose relatives have fallen in the present war, Dr. C. WILLIAMS has written a little study⁷ in biblical eschatology in which the views of the primitive church on death and the hereafter are stoutly reaffirmed. Dr. Williams holds that after death the soul may go to Paradise, to Hades, or to Gehenna, according as it is good, indifferent, or bad. Dr. Williams looks forward with confidence to the coming of the millennium, and claims a real efficacy for prayers for the dead. His book may be recommended as a firm declaration of faith to those who find consolation in speculations on the unknown future that lies before the dying.

The *Minutes of the General Medical Council* and of its various committees for the year 1915, with nineteen appendices,⁸ has been published, and forms a volume of 521 pages. The *General Index to the Minutes of the General Medical Council for 1903-1915*⁸ has also been issued.

⁵ *Appleton's Medical Dictionary*. Edited by Smith Ely Jelliffe, A.M., M.D., Ph.D., assisted by C. W. Latimer, M.D., A.M. London and New York: D. Appleton and Co. 1916. (Demy 8vo, pp. 945, 15s. net.)

⁶ *The Illustrated Medical Dictionary*. By W. A. Newman Dorland, A.M., M.D., F.A.C.S.; eighth edition, revised and enlarged. London and Philadelphia: W. B. Saunders Co. 1915. (Med. 8vo, pp. 1137, illustrated. 19s. net; with thumb index, 21s. net.)

⁷ *Death and Hereafter*. By Dr. C. Williams. London: Jarrold and Sons. 1915. (Cr. 8vo, pp. 94. 1s. net.)

⁸ London: Constable and Co. 1916. Prices 12s. and 2s. 6d. respectively.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee on January 11th twenty cases were considered, and £149 10s. voted to fifteen of the applicants. The following is a summary of the cases relieved:

Widow, aged 56, of M.D. Aberd. who practised at Balham and died in 1904. After husband's death went to South Africa with her son, and invested all her capital in a mine which was a failure. Applicant returned to England at the outbreak of war. Son joined the army in South Africa, and the little allowance he was able to make to his mother ceased. She has earned a little by nursing but not sufficient to keep her. Relieved once, £10. Voted £5 and referred to the Guild.

Widow, aged 42, of M.R.C.S.Eng. who practised in London. Has three young children. Has endeavoured to make a living by running a boarding house, but, owing to ill health and the children, has found it very difficult, and requires a little temporary help. Voted £10.

Wife, aged 39, of a professional man who had joined the army. Applicant's first husband was a medical man, and she had three daughters by him. She has developed tuberculosis, and had to go into a sanatorium, and wanted a little help to complete the education of her youngest daughter, aged 16. Another society has promised a little help; £2 10s. was granted to the Guild, who were also going to assist.

Daughter, aged 49, of M.D.Lond. who practised in London and died in 1900. Was left practically unprovided for, and is very delicate. Only income £19 per annum. For many years lived with a friend who has recently died. Relieved twice, £25. Voted £15 in twelve instalments.

Daughter, aged 63, of M.R.C.S.Eng. who practised in Watford and died in 1879. Applicant unable to work in consequence of impaired health. Only income a pension of £26 from another society. Relieved nine times, £108. Voted £9 in twelve instalments.

Daughter, aged 51, of M.R.C.S.Eng. who practised at St. Clears and died in 1878. Applicant has double curvature of the spine. Lives with her mother, who is an annuitant of the Fund. Relieved twice, £12. Voted £6 in twelve instalments.

Widow, aged 63, of M.R.C.S.Eng. who practised in London and Somerset and died in 1901. Applicant was left quite unprovided for at husband's death. Has managed to earn a little by dressmaking and letting rooms, but has been ill, and recently underwent an operation for uterine fibroids. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 65, of L.S.A.Lond. who practised in London and died in 1890. Applicant has no permanent income, but earns a little by needlework and taking in boarders. Her health is very precarious. Relieved three times, £36. Voted £12 in twelve instalments.

Widow, aged 59, of M.R.C.S.Eng. who acted as locum tenent and died in 1913. Applicant was practically supported by eldest son, who gave up a good position and joined the army, but has been missing since September last. Other son also in army, but only able to allow his mother the usual army allowance. Too old and health not good enough to enable applicant to work. Relieved twice, £20. Voted £12 in twelve instalments.

Widow, aged 51, of M.R.C.S.Eng. who practised in Leicestershire and died in 1902. Applicant was the Morgan annuitant of the Fund for some years. Owing to three sons having joined the army and navy, and not able to make the usual allowances towards the upkeep of the home, and one daughter very ill, applicant has got into temporary difficulties. Voted £5.

Wife, aged 49, of L.R.C.P.Irel. Separated from her husband owing to his habits. Left with three children, the youngest of whom is at Epsom College, and the others hope to be able to earn a little soon and help their mother. Applicant's eyes are bad, and she is quite unable to work. Relieved three times, £36. Voted £12 in twelve instalments.

Widow, aged 59, of L.R.C.P.Irel. who practised at Chester and died in 1907. Applicant was left quite unprovided for; only certain income a pension from another society of £25. Health very unsatisfactory. Has one daughter who is married and unable to help. Relieved eight times, £96. Voted £12 in twelve instalments.

Daughter, aged 61, of M.R.C.S.Eng. who practised at Hunts-pill and died in 1889. Applicant has tried to make a living by letting rooms, but not successfully, and all her capital has been lost in consequence. Only income now a little from needlework. Relieved five times, £60. Voted £12 in twelve instalments.

Daughter, aged 45, of M.D.Heid., L.R.C.P.Lond., who practised in London and died in 1890. Applicant's health is very unsatisfactory. She earns a little by painting, but this is very precarious, especially at present. Relieved once, £12. Voted £10 in two instalments.

Widow, aged 70, of M.R.C.S.Eng. who practised at Maidstone and died in 1910. Applicant was left totally unprovided for and has tried to earn a living by taking in paying guests, but recently has not been very successful, and is too old to try other work. Relieved five times, £42. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for

gifts of secondhand clothing, boots and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

THE PETROL SITUATION.

THE petrol situation is becoming somewhat aggravated. The first hint received by the public was the circular of the Asiatic Petroleum Company referring to a possible shortage, which in turn brought forth a statement from the Anglo-American Oil Company that there was no shortage, but that such statements were likely to send up prices. The situation thus revealed remained an enigma to the public, particularly when, about a fortnight later, all the petrol companies save the Asiatic Petroleum Company (Shell and Crown brands), advanced the price of their fuels approximately 4d. a gallon. Then the Shell people issued a circular again insisting on the need of economy, also claiming that they were supplying four-fifths of the fuel required by the British forces, and concluding with the announcement that in consequence they would make it their best endeavour to supply the public with one-third of its normal peace time consumption of Shell and Crown spirits.

If pleasure motoring were the only thing to be considered, one-third of peace-time supplies would more than suffice for all the driving that is done nowadays. But altogether apart from the enormous demands for motor fuel for the navy and army, alike at home and overseas, our home consumption of petrol for civilian use is unprecedentedly high, primarily because the wholesale commandeering of horses for war service has compelled the community to take to the employment of utility motor vehicles to an extent that has never obtained before. As regards consumption as reflected by the shipping accommodation problem, for a given amount of work done the utility motor vehicle consumes appreciably less than half the tonnage it is necessary to import in the way of food-stuffs for horses doing the same amount of work, so there is a direct gain under that head.

RISE IN FUEL PRICES AND SHIPPING RATES IN AMERICA.

But against this the Government has had to take over approximately half the fleets of tank steamers possessed by the fuel companies, and may have to take more yet, so that there is a real shortage of shipping accommodation for the motor fuel supplies of the civilian community. In wide terms, the tank steamer building for the year will add approximately a third to the world's fleets; but that will barely keep pace with the growing demands under all heads for motor fuel before an allowance of any sort is made for possible losses of tank ships due to enemy enterprise. It therefore follows that in the present situation a very sharp look-out has to be kept on the activities of those oil refiners in various parts of the world who own tank steamers; the bidding for their services for a voyage is very high in consequence. As giving a notion of the extraordinary state in which the freight market is in this connexion I may point out that within the last month I have seen contracts placed ranging from £3 15s. to no less than £6 10s. a ton for petrol to be brought here from America. Both rates are, of course, quite abnormal. Yet the lower figure is the lowest at which business has been done.

Nor is this all; for when the use of a single steamer is secured to bring a cargo of oil here it is, of course, always a condition that the fuel shipped is purchased from the refiner owning the given steamer. For example, not all the petrol imported by the Anglo-American Oil Company comes through the Rockefeller groups. Supplies are purchased from about four separate and independent sources.

Despite the fact that in 1915 and in 1916 there will be added to the motor vehicles in use in the United States alone a total of two million machines—over 800,000 were added last year, and over a million will be added this year—it is a fact that all the petrol we need is obtainable in the world. Put in few words, the situation is simply

this: We can get all the fuel we need and are able to transport, but that fuel is worth just as much as it will fetch on the open market, and we must pay accordingly. In face of the figures I have given concerning the rate at which America is increasing her use of motor vehicles, naturally the oil refiners are not throwing their stocks on the market, but instead wait for bids. They know that they can dispose of all their stocks at home. On the other hand, they have such an enormous foreign demand that the price of home consumption has risen from 15 cents per American gallon in New York a year ago to 35½ cents to-day, and 40 and 50 cent petrol is being spoken of. We have to add one-fifth to every American gallon to make an English one of it, apart from which most of this 35½ cent petrol is equal to only about our third-grade spirit, therefore it has to be refined again when brought over here, which further reduces the quantity.

WHY TALES OF SHORTAGE DO HARM.

The importers claim that the rise of 4d. a gallon barely takes up the advance that has occurred during the last twelve months in the cost of the fuel in the primary markets where they purchase it, and makes no allowance whatever for the current abnormal shipping rates and for the heavier distribution costs in this country. Those costs embrace the two gallon tins in which the petrol is kept and of which there is a great shortage, owing, first, to the heavy demands and destruction in connexion with those supplied for war service in the early days of the campaign, and, secondly, to a section of the motoring community having laid up large fuel stores in two gallon tins, which are accordingly out of circulation for an unduly long time. The authorities solved their own tin problem by taking two steps. The first consisted of organizing adequate repair depôts so that the wholesale scrapping of tins was stopped, and the second was the taking over of the supplies of tin and the tin works, so that for some time past the Government has been making its own petrol cans. In consequence the petrol importers have had to import their tins, which is comparatively a very expensive process.

In face of all these points, therefore, the only marvel is that the civilian community has come thus far through the war without having to pay more than half a crown a gallon for its first-grade motor fuel, particularly as in France considerably more has had to be paid. It will be appreciated that nothing could more adversely influence this matter from our point of view than putting abroad stories concerning shortage of petrol, since the refiners in America are only waiting for such information to hold back their supplies until they can demand still more extortionate prices. In this connexion it must not be forgotten that in the United States they have very full knowledge of the manner in which munition producers there have coined money out of this war, some large orders having paid not only for the cost of production and materials, but also for the factory buildings in which and for the machinery with which they have been produced; and have, besides, left over a balance of 25 per cent. profit on a single order. With the example of successful plundering on such a scale it is not surprising that sundry oil refiners in the New World consider their present game not only absolutely legitimate, but also positively philanthropic by comparison.

"TIN GRABBERS" AGGRAVATE THE DIFFICULTY.

The "tin-grabbers," as the petrol trade describe those members of the community who have aggravated the position at home by laying in stores of petrol sufficient for anything from six to eighteen months and with a view to dodging increases of import duty, should become objects of special attention on the part of the authorities now that the motor fuel situation is having to be dealt with by the Ministry of Munitions. Such individuals have acted against the public interest; therefore their stocks should be seized, if only for the reason that every user of motor fuel should pay duty on it at whatever rate obtains for his given class at whatever time he uses that fuel. In Germany laying up stores of this kind, which are estimated by the Royal Automobile Club to total over a million cans, would be punishable by heavy fine, for with the total number of cans in the country enormously diminished by reason of the army's needs at the beginning

of the war, the having an additional million withdrawn from use by these undesirable tactics of comparatively a small section of motor users becomes a very serious thing to the community. Every additional can has to be imported into these islands, consequently each one should be made the vehicle of distributing two gallons of petrol as frequently as possible in place of containing the same two gallons of petrol for month after month. This is one of the first points that should be made by the medical profession when making a move, as it must do, to have its case specially considered by the authorities at the present juncture.

MEDICAL MEN MUST BE ASSURED OF SUPPLIES.

Next it should bring out the need for supplies of petrol being assured to medical men throughout these islands according to their several needs. The Commercial Motor Users' Association, which claims that more than 75 per cent. of the petrol used by the civilian community of these islands is required by the industrial and commercial motor vehicle users, has been invited by the Ministry of Munitions to submit a scheme to secure a more efficient distribution of petrol. The fact is overlooked that of the balance of less than 25 per cent. used by the civilian community at the moment by far the greatest proportion is needed for professional uses, foremost among which are doctors. Motors are besides needed by veterinary surgeons, surveyors, civil engineers, and all manner of other professional men, whose collective requirements nevertheless do not come within the scope of the Commercial Motor Users' Association's claims.

The Motor Trades' Association did well in advertising the limit which motorists ought to pay for their petrol supplies in England, Scotland, Wales, and Ireland at the present time. But the association is, of course, unable to compel local retailers who desire either to favour certain customers or to hold up supplies to release what stocks they may have in hand. To put the retailing of petrol into the hands of the Government by any sort of machinery that could be devised would only be adding expense to expense and creating a number of paid posts for officials, which form of national extravagance must be stopped at all costs, now we have gone thus far in the war and all realize that every penny must be looked at twice before it is spent.

Of course, the main causes of the, at present, admittedly unequal distribution of petrol are unavoidable. They arise from certain consignments intended for civilian use being diverted at the last moment to some point or other where the Government desires them to be placed for its own disposal for military purposes, whereby a month or two may pass before it is possible to arrange for another cargo to be brought to the given centre. This difficulty could be obviated as far as medical men are concerned, however, by arranging that each shall be allowed to accumulate anything from, say, two to four dozen tins, according to his situation, whereby it would be possible to carry on for a matter of weeks in the event of any temporary interruption in local distributing arrangements.

THE Chile Minister of Justice has appointed a Commission for the study of crime. A laboratory of experimental pathology is to be established at Santiago.

It appears from a report by the Medical Officer of Health of Vienna, Dr. Böhm, that during the first twelve months of the war the health of Vienna was in many respects better than might have been expected. The number of patients treated in public and private hospitals was 79,169, as compared with 119,935 for the preceding twelve months. Many men had left the town on active service, and the conditions of labour and pay were much improved for those who stayed at home. The death-rate was 14.5 per 1,000, as compared with 13.6 per 1,000 for the last twelve months of peace. Of the infectious diseases commonly associated with warfare, only small-pox assumed alarming proportions; and for this the lack of universal vaccination was to blame. In the first twelve months of the war 1,613 cases were notified in Vienna, 1,538 in the civilian population, 50 among soldiers, and 25 among civilians not domiciled in Vienna. There were 351 deaths, and the mortality was, therefore, 21.7 per cent. Only a few cases of cholera, typhus and dysentery occurred, and the incidence of typhoid fever among the civil population was nearly normal.

THE REPORT OF THE ROYAL COMMISSION ON VENEREAL DISEASES.*

(Continued from p. 346.)

II. PREVALENCE (continued).

Distribution of Venereal Disease.

THE crude death-rates from syphilis per million for the year 1910 are stated to be 46 for England and Wales, 42 for Scotland, and 22 for Ireland. Such consequential diseases as general paralysis, locomotor ataxia, and aneurysm follow syphilis closely in relative order of distribution, except that aneurysm stands highest in Scotland, and, together with general paralysis, is markedly low in Ireland. The table brings out the fact that syphilis is essentially a town disease. It is concluded that the excess of urban mortality from syphilis is due largely, but not altogether, to the high proportion of institutional deaths returned by them. For gonorrhoea no similar statistics are available, but the trend of the evidence is to show that, like syphilis, it is essentially a town disease.

The infantile mortality returns due to syphilis again show the striking immunity of the rural areas: it is one-half that in urban areas. The mortality of illegitimate infants is from 8 to 10 times as high as that of the legitimate.

A most striking table gives the recorded death-rate per million for syphilis and three consequential diseases in classified groups of the population above 15 years of age. The rate is heaviest for unskilled labour; next in heaviest incidence comes the upper and middle class which includes clerks and insurance agents; then follow in order skilled labour, textile workers, miners; and last, with the lightest incidence, agricultural labourers. "As the figures were standardized to allow for the varying age distribution among classes whose average duration of life differs, they may be accepted as correctly representing the relative incidence within the limits of accuracy permitted by the present system of registration. . . . Viewing these figures as a whole, we consider that there are good grounds for believing that the prevalence of syphilis is greatest amongst the highest and lowest of the social classes. . . . Incidentally the figures help to confirm and explain the geographical distribution with which we have dealt."

Defects in Registration.

The report comments on the bad system of death registration in the United Kingdom; not only does the publicity of the certificate reduce its possible value, but there is no uniform method, and no provision for collating and analysing the returns as a whole. In England and Wales the doctor gives the certificate to the friends of the deceased, in Scotland he is supposed to send it to the registrar, but it is not confidential and a copy may be got for a small fee. In 1893 a Select Committee of the House of Commons commented on this unsatisfactory state of affairs, and "recommended that medical practitioners should be required to send certificates of the causes of death to the registrar, instead of handing them to representatives of the deceased." No official action has been taken, and bills presented by private members made no progress. But none of these attempts laid stress on the necessity for the document being confidential. The report points out that under a proper system "this certificate would be confidential, and access to it would only be possible on the order of a court of justice. A number of witnesses gave evidence in favour of confidential certification of the cause of death, and we understand that a reform of this kind has for some years been advocated by the British Medical Association, and is generally supported by the medical societies." Strangely enough, the view of the life assurance societies, so far as it was expressed, was opposed to confidential registration. But the Commissioners state: "We are not convinced by the alleged objections, and we consider that any improvement in the accuracy of vital statistics must, in the long run, benefit the life insurance companies, who could adopt their methods to the system of confidential certification as in all other great European countries." The Commission recommends that the Notification of Births Act should be made universally operative, and this has been done. It

* Royal Commission on Venereal Diseases. Final Report of the Commissioners. [Cd. 8189.] Price 1s. 11d.

also recommends that stillbirths of an earlier period than the Act specifies should be notifiable.

Defects of Hospital Statistics.

Stringent comment is made on the lack of information furnished in response to the appeal to the voluntary hospitals; 285 were applied to and only 67 replies were received.

Although in a few cases much trouble was taken in filling up the forms, the figures obtained are, for various reasons, unsuitable for our purpose, and there can be little doubt that in a large number of hospitals adequate records for statistical purposes are not kept. It appears to us to be highly unsatisfactory that these institutions, which are maintained from funds of a semi-public nature, should be unable to furnish precise information respecting the diseases with which they deal, and we trust that this important question will receive the serious consideration of the managing bodies.

The next paragraph of the report deals with the response of the Poor Law unions, and it would appear that their returns were of even less use than those of the voluntary hospitals.

We are strongly of opinion that improved records of sickness in hospitals and Poor Law institutions are urgently needed, and we consider that the Local Government Board should devise a uniform system with the object of securing statistical information as regards the prevalence of disease among persons who receive institutional treatment.

III. EFFECTS OF VENEREAL DISEASE.

The section on the effects of venereal disease is an admirably written clinical essay. Syphilis and gonorrhoea are dealt with. The early and late effects of these diseases, arterial disease of syphilitic origin, syphilitic diseases of the nervous system, and the grave risks of blindness, and also the fact that syphilis predisposes to cancer of the tongue, are commented on, as is the importance of gonorrhoea in women, not only because of the suffering entailed, but since it is said to be the commonest cause both of absolute and relative sterility—"in women probably 50 per cent. of all causes." "Knowledge of these facts should, in our opinion, cause both the medical profession and the public to take a far more serious view of gonorrhoea than has hitherto been adopted." The effects of gonorrhoea on little girls are noted, both when the disease arises from accidental causes and by attempts at sexual intercourse, "sometimes attributable to the abominable superstition that intercourse with a virgin cures venereal disease in a man."

Effects of Venereal Disease on Offspring.

"We have received much evidence showing that both in the fetus and in the child after birth hereditary syphilis is an even more serious disease than the acquired form." It is a frequent cause of antenatal death, producing abortion, miscarriage, or stillbirth. "It will be seen that the figures furnished by one witness, which relate to 150 (syphilitic) families, show that out of 1,001 pregnancies 172 resulted in miscarriages or stillbirths."

The gravity of the diseases set up in the child in the earlier and later periods of its growing life by the virus are commented on. "Of 1,100 children in London blind schools, Mr. Bishop Harman states that 31.2 per cent. of cases were certainly, and in addition 2.8 per cent. probably, due to syphilis." Again, "Of 845 children suffering from some acquired deafness in London County Council deaf schools, 7.21 per cent. were adjudged to be congenital syphilitic." Ophthalmia neonatorum as a cause of blindness is nearly as grievous. The London blind schools figures showed that 24.35 per cent. of children were in the blind schools from this cause, and for a small group in the Bristol school 41 per cent.

As to the relation between alcohol and venereal disease, the Committee says that alcohol "renders a man liable to yield to temptation which he might otherwise resist, and aggravates the disease by diminishing the resistance of the individual." It makes latent disease active, and renders a case more refractory to treatment.

Economic Effects of Venereal Disease.

Fetal and infantile death and sterility in women and in men due to venereal disease are a heavy toll on the vitality of the nation. Disease renders the living of little economic

value. The London figures of the blind referred to show that—

The total percentage attributable to venereal disease was certainly 55.6, and may have been as large as 58.4. To the expenditure incurred in the treatment of these children must be added the additional cost of their education. . . . The figures published by the London County Council indicate that the total cost of educating a child in the day schools for the blind is about seven times the cost of the education of the ordinary child. . . . Dr. Kerr Love stated that the cost of educating a deaf child is ten times as great as in the case of a normal child.

To these add "imbecility, idiocy, and various . . . other diseases, . . . the total . . . cannot be estimated."

Among adults the loss of working power from the earlier effects of the disease is important. "The naval statistics for the year 1912 show for an average strength of 119,510 men a total number of 269,210 days lost as a result of venereal diseases; in the army at home during the same year . . . with a strength of 107,582 men . . . a loss of 216,445 days. . . . If corresponding figures from the civil population could be obtained they would be found to be extremely large," especially when the deficient provision for treatment is considered.

The loss due to late effects is equally grave. "The statistics of the London County Council asylums show that 8 per cent. of the total admissions, or 15 per cent. of the male and 3 per cent. of the female admissions, are due to cases of general paralysis of the insane." The cost of all the lunatics in these asylums is £600,000 a year. It is estimated the total cost of asylum treatment in England and Wales from syphilis alone is £150,000 a year; "it cannot be less, and may be much more."

IV. MEANS OF TREATING OR PREVENTING DISEASE.

This is the final and naturally the most important section of the report, for it contains the recommendations of the Commissioners.

Diagnosis.

At the outset they insist on the necessity for early and accurate diagnosis.

Early correct diagnosis is the basis of early satisfactory treatment, cure, and prevention of the disease. Much can be accomplished in the prevention of venereal disease by education, and by arousing the public conscience to the great dangers, both to the individual and the community, of the neglect of infected individuals to seek competent medical advice as early as possible; this is particularly important in cases in which the existence of infection is doubtful or where the symptoms and signs are liable to be disregarded on account of their mild character and the absence of pain or discomfort. Every inducement should be offered, and no social, economic or administrative disabilities should prevent any sufferer with a venereal disease, however slight, from obtaining an accurate diagnosis with a view to satisfactory treatment at as early a date as possible after infection.

Comment is made on the advantages to be derived from the extended use of laboratory methods of diagnosis and the necessity for uniformity in the methods adopted. "The general practitioner will not as a rule have facilities for carrying out these tests for himself. He can, however, readily collect the material necessary for examination by either method and send it by post to the pathological laboratory. The presence of the spirochaete in a discharge can be shown several days after collection."

Treatment of Syphilis.

With regard to the results of treatment of syphilis, the report contains the following passages:

The only certain proof of eradication is reinfection. Since the introduction of the modern diagnosis and treatment many cases of reinfection have been reported. Syphilis may therefore be regarded as a curable disease. It cannot be too widely proclaimed that no grave disease responds more readily to efficient medical treatment than syphilis, and there are good grounds for concluding that eradication of the spirochaete with complete cure, or a total absence of any subsequent signs or symptoms of the disease in the majority of cases, can be obtained by "intensive treatment" when commenced in the primary stage.

There follows an excellent summary of the results of mercurial treatment, the use of arsenical compounds, the preparation by an English firm of substitutes for salvarsan and their testing by the Medical Research Committee. The reports on kharsivan and novoarsenobenzol are excellent, and there is conclusive evidence that in these thoroughly reliable and efficient preparations have been obtained. Galyi is also well spoken of.

The combined arsenic and mercury treatment (intensive treatment) introduced by Neisser is most recommended for general adoption.

This consists of periodic intravenous injections of salvarsan, followed by a course of five intramuscular injections of an insoluble mercurial preparation (calomel cream or grey oil) or a course of 30 inunctions. This is recognized by most experienced authorities as by far the most satisfactory method of treatment, and if commenced in the primary or even early secondary stage and continued for a sufficient length of time it will, in the majority of cases, result in a complete absence of symptoms, with the permanent absence or disappearance of the Wassermann reaction.

The opinion is expressed that in all cases success must largely depend upon the intelligent and loyal co-operation of the patient, and no means to ensure early and adequate length of efficient treatment should be neglected. Ignorance regarding the infectivity of the disease is largely responsible for its spread among the poorer classes, and patients should be warned of the danger of infecting innocent persons, and especially women, by whom the disease may be transmitted to their offspring. This vitally important object may, the Commissioners consider, be secured by issuing to every patient suffering with syphilis a card of instructions in some such form as the following:

Instructions to Patients.

1. Syphilis is a contagious disease; it can be cured if promptly treated by a doctor.
2. Treatment by quacks, herbalists, or persons advertising so-called cures is likely to lead to disastrous results.
3. The infection may last several years. It can be conveyed to others by sexual intercourse, by kissing, or by using the same eating or drinking vessel, utensils, or tobacco pipes, etc.
4. Treatment should not be stopped until the doctor says this may safely be done.
5. Should signs or symptoms of the disease appear, such as a rash on the skin, sore throat, or symptoms of nervous disease, a doctor should be at once consulted.
6. A doctor should be consulted occasionally, even though there are no symptoms of a return of the disease.
7. Treatment need not as a rule interfere with work or necessitate stay in hospital.
8. No one who has, or has had, syphilis should marry without permission of the doctor; otherwise there is great danger of giving the disease to wife and children.
9. Teeth should be cleaned night and morning. The patient should dress warmly, live simply, and avoid wine, beer, spirits, and other intoxicants.

The Commissioners strongly express the opinion that "the moral obligation should be urged upon all doctors who treat the disease in institutions or privately, to hand these cards, which should be provided at the public expense, to their patients."

The Treatment of Gonorrhoea.

Early recognition and prompt measures to prevent the spread of the organism to the posterior parts of the infected urethra of the male is insisted upon. The use of suitable injections, for which several colloidal preparations of silver are mentioned, is a striking advance on the old-time palliative measures and internal medication. As in the case of syphilis, the Commissioners recommend that cards of instruction, to be handed to patients suffering from gonorrhoea, should be provided at the public expense, and suggest that these instructions should be in the following or similar form:

Instructions to Patients.

1. Gonorrhoea is a contagious disease contracted through sexual intercourse. Gonorrhoea may be attended by grave consequences, especially if treatment be neglected and the necessary precautions are not taken.
2. Treatment by quacks, herbalists, or advertisers is likely to lead to disastrous results.
3. Sexual intercourse must on no account be indulged in while there is any discharge, even though this may be only slight. If this rule be neglected the condition is made worse. Moreover, there is always danger of communicating the disease.
4. Gleet, a late form of gonorrhoea, associated with a slight chronic discharge, is very likely to communicate the disease to the wife, causing much suffering and sometimes leading to chronic invalidism and barrenness.
5. Care must be taken that the discharge is not conveyed to the eyes. Neglect on this point may lead to injury to eyesight or to blindness.
6. Large quantities of simple fluids should be drunk, but no wine, beer, spirits, or other intoxicants should be taken while the discharge continues and for some considerable time after it has stopped.

The particular necessity for prompt measures in the case of women is insisted upon, as is the difficulty of the

situation owing to the failure of patients to recognize the onset of disease from their confounding it with an ordinary leucorrhoea.

Existing Facilities for Diagnosis and Treatment and their Deficiencies.

In private practice facilities are increasing for diagnosis among the well-to-do and the knowledge of their advantages is spreading. Amongst the wage-earning and other less well-to-do classes the skilled pathologist is unavailable except for the scanty aid given by a few sanitary authorities and voluntary hospitals. "The lack of facilities for diagnosis undoubtedly accounts for the large amount of venereal disease, and particularly syphilis, which, not being recognized at an early stage, is inadequately treated or entirely neglected."

In Poor Law practice and that under the Insurance Acts "pathological aids to diagnosis have only been utilized to an inconsiderable extent." In voluntary hospitals the position is more advanced: "There is evidence that the provision of clinical laboratories available for aiding the diagnosis of gonorrhoea and syphilis has materially increased." Of public health authorities, it is written: "In the majority of sanitary areas in this country no official pathological facilities for the diagnosis of gonorrhoea and syphilis have hitherto been provided. . . . In the navy and army the facilities are better developed than in the rest of the community." In prisons "there are no adequate arrangements."

The facilities for treatment follow very much the same lines. "People of the middle and upper classes are treated almost exclusively by private practitioners or by consultants, except in the numerous instances in which, from shame or because they are misguided by advertisement or misleading recommendations, they consult chemists or unqualified persons." It is asserted that the training of medical students with regard to the diseases is insufficient, so that medical men do not always regard them with enough seriousness.

Under the Insurance Act, which covers roughly one-third of the total population of the United Kingdom, "an insured person suffering from gonorrhoea or syphilis is entitled to receive medical attendance and treatment, and to be supplied with the necessary medicine and appliances, exactly in the same way and to the same extent as for other diseases." But the patients are otherwise penalized. The model rule of the Insurance Commission is:

No members shall be qualified for sickness or disablement benefit in respect of injury or disease caused by his own misconduct; but no member may be suspended from benefit for a period exceeding twelve months.

The Commission reports that "The application of any such rule in the case of venereal diseases is likely to deter patients from seeking prompt and efficient treatment. It is therefore contrary to the interests both of public health and economy."

The possibility of the general use of salvarsan in private work is considered; the views of witnesses differed. The conclusion in the report is: "We are strongly of opinion that training in technique is necessary in the case of all medical practitioners who administer this drug, and the means will become available if our recommendations are adopted."

In voluntary hospitals the accommodation for treatment is altogether insufficient.

Patients apparently recognize that the treatment of venereal disease is not encouraged in general hospitals. . . . In some hospitals it is contrary to their statutes to admit venereal disease into the institution.

There is evidence that considerable objection to the treatment of venereal disease in the voluntary hospitals persists in the minds of some of the subscribers to these hospitals.

It appears that, although there is a certain amount of modern treatment available for venereal patients at special hospitals, the amount is limited, and that the workhouses and their infirmaries do not at present to any extent supply the lack. Special hospitals have done excellent work, but these are few in number.

Recommendations for Improving Facilities for Diagnosis.

Prior to the outbreak of the war the House of Commons voted £50,000 to assist in the provision of laboratory facilities "with a view to the prevention, diagnosis, and treatment of disease in general." This was intended to be

a grant in aid of the provision of pathological laboratories by the large public health authorities. "If these proposals are made effective much expenditure, which must otherwise be provided elsewhere for the treatment of venereal disease, will be saved." Where adequate facilities already exist in universities and large hospitals these should be made use of.

They "would form satisfactory centres for diagnosis; they would, moreover, have the advantage of being intimately associated with the clinic and treatment. Similarly, the services of the London Lock Hospital, which has done useful diagnostic work in the past, should be fully utilized." The recognition of the importance of a pathological laboratory to the efficiency of a hospital should receive every encouragement, and those borough and county hospitals which are of sufficient size and importance to equip and maintain a pathological laboratory with an efficient salaried pathologist should (after approval by the Local Government Board) be admitted as centres for a county or district.

Recommendations for Improving Facilities for Treatment.

Its review of the present conditions has made it clear to the Royal Commission that, except in the case of the navy and army, the existing facilities for the treatment of venereal diseases are extremely deficient.

The medical practitioners of this country are, from the nature of the case, to a large extent unfamiliar with the newer methods of diagnosis and treatment. . . . The institutional provision which has been made for the treatment of the diseases is . . . wholly inadequate.

It was the general opinion of the witnesses who appeared before us that no adequate system of treatment would be organized unless responsibility for the measures to be adopted were undertaken by the State. In these opinions we concur. We recognize that the medical practitioners of the country must form the first line of defence against these diseases, but the diseases are so widespread and their consequences are, as we have shown, so serious, not only to the individual but also to the race, that concerted action by a public authority is in our view essential.

The recommendation is that the councils of the larger local authorities should undertake definite schemes for the treatment of venereal diseases in their areas. The institutional treatment to be provided should be available for the whole community and should be so organized that persons affected by the disease will have no hesitation in taking advantage of the facilities for treatment which are offered. The Commissioners find that special centres are undesirable, and consider that "the most practicable method is the use of special wards in the general hospitals of the country, together with special arrangements, including evening clinics which are essential to the working classes, at these hospitals for the out-patient treatment of the disease," and continue:

"We are satisfied that the existing hospital facilities, with such extensions as may be found necessary, should suffice to meet the need for the prompt and satisfactory hospital treatment of most of the venereal disease in this country."

"The condition that the institutional treatment should be available for the whole community is one to which we attach cardinal importance . . . to ensure the application of patients for treatment at the outset of the disease, and to maintain continued attendance until the doctor certifies that the patient is free from infection." If a patient can afford to pay for treatment he should be referred to his own doctor, nevertheless "if the patient be unwilling, there should, in our opinion, be no refusal to treat him at the institution." "The treatment at a particular institution should not be confined to those living within a certain area."

"It is essential that medical students and practitioners should have access to the treatment of these diseases at any institution dealing with venereal diseases as part of a local authorities scheme. This is of the greatest importance from the educational point of view. It is also essential that the co-operation of the practitioners with the local authority and the hospital should be obtained. We consider that any scheme of administration for dealing with venereal diseases must be framed so as to develop the ability of the general practitioners in treating these diseases, and make them more efficient for their general functions as the first line of defence of the community."

It is pointed out that at present "the Local Government Board have power under the Public Health Act to authorize the supply of salvarsan or its substitutes free

to medical practitioners, and we consider that great advantage would result from the exercise of this power."

Notification of Venereal Disease.

On this head the report says that "in enforcing the notification of any disease the community has in view primarily the taking measures for the protection of all its members . . . in preventing the spread of infection . . . and in some cases the removal of patients to hospital . . . the patient himself may be subject to penalty if he do anything at the risk of spreading infectious disease." These provisions apply in practice almost exclusively to the acute infectious diseases, though in some cases the wording of the statute appears wide enough to cover other diseases. As regards venereal diseases, it is judged that "the adoption of notification would doubtless have an important effect in emphasizing the infectious character of these diseases, and in causing their dangerous nature to be widely known." It "has also been advocated as an aid to the removal of conditions favourable to their propagation, such as bad housing and overcrowding."

The Commissioners, however, sum up this part of the subject as follows:

We think it clear, however, that if a case for notification of venereal diseases is to be established it must be based upon the assistance which notification would afford to the treatment of the individual and the consequent protection of the community, and not on the ground that it would facilitate general preventive measures.

The essentials for their treatment and prevention are prompt diagnosis and prompt and continuous treatment. The majority of medical witnesses were of opinion that there would be reluctance on the part of practitioners to notify cases, and if compelled by law, the result would be an even greater resort to unqualified persons.

To compel unqualified persons to notify would be impossible owing to the difficulty of proving that they knew the nature of the case. After considering the *pros* and *cons* for notification the report concludes:

The main objection which has been urged against notification of venereal diseases is that it would actually do more harm by deterring people from seeking treatment and by driving them more than ever into the hands of unqualified persons.

It is possible that the situation may be modified when these facilities (for treatment) have been in operation for some time, and the question of notification should then be further considered. It is also possible that, when the general public becomes alive to the grave dangers arising from venereal disease, notification in some form will be demanded.

Anonymous notification for statistical purposes was considered, but the conclusion arrived at was that it would not be satisfactory. The necessity for careful taking of statistics of patients treated is urged, especially with regard to the administration of salvarsan.

Detention of Persons Suffering from Venereal Diseases.

The Commissioners consider that the provision of free treatment would be useless if the treatment were not carried out to its termination, and make the following observations:

A person may discontinue his treatment when, though he is still infectious, the immediate symptoms have disappeared, and he is thus able to spread the disease, and may afterwards return in as bad or a worse state to be treated again.

The application of compulsion to cases in which there is no sense of responsibility, where no restraint is thought of, and where contagion is in its most active and virulent form, can be defended on strong public grounds.

Apparently in Denmark the doctors have the power of detaining hospital patients until free from infection, but it appears the power is not rigidly enforced. Under the Poor Law Amendment Act, 1867, Section 22 gives this power to the workhouse authorities on the certificate of the medical officer, but "doubts have arisen whether this provision is applicable to the case of venereal diseases." The discharge of infectious patients from prisons calls for special attention, particularly as it appears that the figures for those on short sentences are by no means complete. It would seem desirable that any doubt on the power to make a Wassermann test or administer salvarsan "should be removed by the addition to the statutory power of the Prison Commissioners." After observing that "the case for the detention of prisoners suffering from venereal disease until they are no longer a danger to the public is a strong one, and in some countries action of this kind is already taken," the report points out that this would

cause hardship in the cases of short sentences, the detention would present a "harder penalty than that inflicted for a more heinous offence on one without manifest venereal disease." In the case of the services, though there is no power to detain men against their will whose period of service has expired, there is power to continue the treatment in hospital after discharge. It appears that this practice is usual in the army but needs reinforcing in the navy.

Treatment of Venereal Diseases by Unqualified Persons.

Fear of disgrace and desire for concealment foster self-treatment or resort to quacks. "This is true of all sections of the community, and we are informed that the upper classes resort to quacks as readily as the poor." The quack thrives on secrecy, credulity, and ignorance of the seriousness of the disease. He promises quick cure, no publicity, no inconvenience, and small cost. The following passages are quoted in full:

"Unqualified practice exists in several forms; many chemists prescribe for the diseases; in some parts of the country herbalists are largely resorted to, while attractive advertisements of remedies by persons who claim to be specialists in venereal diseases are common in certain newspapers and elsewhere."

"We have no hesitation in stating that the effects of unqualified practice in regard to venereal diseases are disastrous, and that in our opinion the continued existence of unqualified practice constitutes one of the principal hindrances to the eradication of those diseases."

"By the intervention of the unqualified person, the stage at which the permanent eradication of the disease is possible is lost . . . treatment is rendered more difficult, protracted, and expensive, and the risk of the disease being communicated to others is very largely increased."

Further, quacks by wrong diagnosis "in order to retain a patient, or from ignorance, are not infrequently responsible for causing much unnecessary suffering and acute mental depression, leading in exceptional cases to suicide."

"We were informed that, in some parts of the country, herbalists are largely resorted to, and we therefore took evidence of a representative of the National Association of Herbalists. This evidence speaks for itself, and in our opinion effectually disposes of the claims of herbalists to be regarded as competent to treat venereal diseases."

The hope is expressed that the education of the public in these matters, and the proposed provision of free treatment will tend to diminish unqualified practice. In the army, in Denmark, and in Italy, where some such conditions exist, this result is attained, and the Commissioners continue:

"We strongly endorse the recommendations of the Select Committee on Patent Medicines that all advertisements of remedies for venereal diseases should be prohibited."

"We should have advocated legal provisions making the treatment of venereal diseases by unqualified persons a penal offence, but we recognize the practical difficulties in securing the effective operation of such a law in present circumstances."

Marriage and Communication of Disease.

The misery and suffering caused by the marriage of an infected person, through communication of the disease to the healthy partner and to the children, was testified to by many witnesses, and the report contains the following observations on this point:

The question, therefore, arises what steps can be taken which may have the effect of preventing the marriage of persons while in an infectious condition from venereal disease. Various suggestions have been discussed in the course of the evidence as to the possibility of legislation preventing the marriage of such persons unless and until the intending husband or wife is certified by a competent authority to be in a condition to marry with safety. We are of opinion that all such suggestions are impracticable at present. . . .

The position of the medical practitioner who knows of intended marriage of an infected person is unenviable. He

may not be able to restrain the purpose of the infected person, and he dare not intervene to check the marriage. The Commissioners report:

"We think that a change in the law in this respect is much needed. We, therefore, recommend that such communication, when made bona fide to a parent, guardian, or other person directly interested in the welfare of the woman, or the man, and with the object of preventing or delaying a marriage with a person who is in an infectious state, should be deemed to be a privileged communication. This proposal is supported by the high authority of the President of the Probate Division."

The Commissioners also support the recommendation of the Royal Commission on Divorce and Matrimonial Causes that the marriage of an infected person should be ground for obtaining a decree of annulling the marriage by the injured party. They believe that this provision would strengthen the hands of the medical profession in checking or delaying dangerous marriages.

Education.

The medical evidence has led the Commission to the conclusion that the average education of medical men in the diagnosis and treatment of venereal diseases is insufficient. The overcrowded state of the medical curriculum, and the fact that syphilis must be studied in relation to disease of most of the organs, complicate the proposal for a special course. But the necessity for special teaching and the possibility of study in the proposed clinics is urged:

We consider that one of the most successful means to secure increased attention to the early and correct diagnosis of these diseases would be that questions relating to syphilis and gonorrhoea should be systematically set in medical examinations, so that the knowledge acquired in these diseases by examinees may be properly tested. The President of the General Medical Council stated that this was already done to a large extent.

The education of the public is a more difficult matter. Children under 14 are rarely fit for instruction in such subjects, and the Commission support the objection to "schematic instruction." They agree in the value of the growing practice "of head teachers to have private interview with pupils before they leave school to give moral instruction and to offer warnings against probable temptations." In public and secondary schools the need for teaching on these subjects is considered to be greater owing to the fuller age of the pupils.

We believe the subject is receiving increasing consideration on the part of the heads of such schools.

Much remains to be done in the universities by those who are responsible for the moral welfare of the undergraduates.

Books and pamphlets have been brought to our notice which are not only unsound from a medical point of view, but are calculated to be injurious by reason of the way in which the questions are treated. We consider that no such publications should be countenanced by educational authorities unless issued with the imprimatur of the National Council for Combating Venereal Disease.

The report adds:

We look to the various voluntary agencies which have been formed for promoting the welfare of the young of both sexes as important aids in carrying out the objects we have in view. Associations such as the White Cross League and the Alliance of Honour have already done valuable work, but much can be done also by properly managed boys' and girls' clubs, the Boy Scouts, the Boys' Brigades, and other similar agencies.

The fact that we recommend that free treatment should be provided for all sufferers makes it, in our opinion, all the more necessary that the young should be taught that to lead a chaste life is the only certain way to avoid infection.

The report concludes with an expression of hope that the publicity given to the matter by reason of this inquiry will lead to a public enlightenment of the dangers of the diseases, and the folly of doing anything to prevent their early diagnosis and treatment. "There can be little doubt," it says, "that a franker attitude towards these diseases would lead to less concealment, often involving recourse to quack remedies, which may retard cure or render it impossible, and would thus assist in checking one of the greatest evils that can afflict a community."

THE late Sir George Scott Robertson, K.C.S.I., M.P., Lieutenant-Colonel I.M.S. (retired), left estate valued at £59,411.

British Medical Journal.

SATURDAY, MARCH 11TH, 1916.

THE OBJECT AND PURPOSE OF ENROLMENT.

It may be advisable to state once again very briefly the purpose with which the Central Medical War Committee and the Scottish Medical Service Emergency Committee have established the system of enrolment, of which all medical men under the age of 45 next birthday are asked to take advantage. Its object is to supply the needs of the army, while safeguarding those of the civilian population and minimizing the loss and inconvenience to individual practitioners. Its purpose is to place in the hands of the professional bodies mentioned the names of all civilian medical men of military age—that is, under 45 next birthday—together with the particulars of the obligations, public and private, of each man. These medical bodies being fully informed of the position and difficulties of each man and each district will weigh them against those of other men in the same and other districts, so that those who can go with least detriment to their own interests and those of others may first be asked to fulfil the obligation under which enrolled men place themselves to accept a commission in the Royal Army Medical Corps. Not every man who enrolls will be wanted by the army, but the Committees, having all the facts before them, will be able to nominate, when called upon to do so by the War Office, the number required from among those who can at the time be spared most easily from their ordinary occupation. Ample notice will be given to each man when a call is likely to be made upon him, and, as will have been seen from the official statement published last week (p. 348) and the Army Council Instruction printed in the SUPPLEMENT to this issue (p. 43), the War Office recognizes enrolment as fulfilling the obligation of medical men who are attested, or who come under the Military Service Act.

At its meeting on March 1st the Central Medical War Committee had before it the War Office statement, and took action thereon. The Army Council Instruction in the SUPPLEMENT this week is very explicit, and we only desire now to call attention to two points. The first is that the present is in accordance with previous announcements: that doctors who have undertaken to accept a commission in the Royal Army Medical Corps, if offered one, will not be taken for general service; and the other, that doctors will not be called up, whether by reason of attestation or under the Military Service Act, until after March 31st, 1916. The Central Medical War Committee instructed its Executive Subcommittee to consider at once in what way the enrolment scheme can be pushed to the maximum success, and to take steps to ensure that result. The Executive Subcommittee met on March 3rd and resolved to send a communication at once to all unenrolled practitioners under 45 next birthday, and to make an immediate canvass of them. The Military Service Act applies only to single men under 41, but it is recognized to be important that all men under 45 should enrol so that the Committee and the War Office may have full information as to the number of medical men available. Two

special canvassing committees have been appointed, one for London and the other for the provinces, and both these committees met in London on March 8th. A circular to canvassers has been drawn up and is published in the SUPPLEMENT (p. 41).

The secretaries reported that the number of commissions posted from July 17th, 1915, to February 26th, 1916, was 1,501, an average of a little over 48 a week. The applications for commissions which had not yet been posted numbered 383. Between February 26th and March 3rd 435 certificates of enrolment had been issued. Local Medical War Committees, it was stated, had been formed in all districts with one exception—Dover.

THE REPORT OF THE ROYAL COMMISSION ON VENEREAL DISEASES.

DURING the South African war the army records showed a marked fall in the incidence of venereal disease, but with the return home of the troops the incidence increased. If any likeness may be expected between the conditions prevailing during and after that smaller war and those that may arise from this colossal struggle, then the report of the Royal Commission on Venereal Diseases is timely indeed.

We hope that the abstract of the report, the publication of which is concluded in this issue, will stimulate every reader to procure and study the original document, for it demands the thoughtful and critical consideration of medical men and women. It is certain that the nation at large will be profoundly moved by the picture it presents, and our profession must be prepared to give a balanced opinion on the practical recommendations that are based thereon.

The recommendations are of no dramatic character; rather they are essentially of a humdrum and everyday order. But they are none the less worthy of attention. They raise no thorny hedge of moral conflict to separate the best ethical instincts of humanity from the practical humanity of our profession. Details of procedure apart, there is no recommendation for the practical realization of which the sternest moralist and the medical practitioner cannot unite.

In the introduction to the report previous legislative enactments are cited, and of certain of these it is written: "Although the Commission are precluded by their terms of reference from considering the policy of the Contagious Diseases Acts, they wish to place on record their view that the evidence they have received, which includes that of several Continental experts, points to the conclusion that no advantage would accrue from a return to the system of those Acts. So far from this being the case, it is to be noted that the great improvement as regards venereal diseases in the navy and army has taken place since the repeal of the Acts."

The section dealing with the prevalence of venereal diseases is the least satisfactory part of the report, for the reason that, apart from the navy and army, no sufficient statistics exist. Many independent witnesses presented evidence of great value, but there was none for the country as a whole. Despite this lack, certain points are made clear. Venereal diseases are diseases of towns and cities, and not of the countryside. They are diseases of the highest and lowest of the social classes for which data is available. At the worst computation there is no ground for the alarmist reports of certain crude "social reformers" who have filled our ears with cries that in this people, "from the sole of the foot even unto the crown of the head there is no

soundness . . . but wounds and bruises and putrefying sores." But there is enough of the evil to demand radical treatment, more especially since the innocent suffer grievously in the punishment of the guilty.

The lack of statistics is a matter for caustic comment in the report. The unsatisfactory state of death certification is dealt with, and a strong recommendation made for confidential certification, a reform "for some years advocated by the British Medical Association." The voluntary hospitals are sharply taken to task for their failure to respond to the appeal of the Commission for figures of their patients. That criticism is not wholly justified. The appeal was made in such fashion as almost to ensure failure. It is otherwise with the navy and army medical services. It should be otherwise with the medical branches of the civil services; but the figures of the Poor Law institutions, police, and prisons are as poor as those of the voluntary hospitals. The failure of the Poor Law authorities is the more surprising seeing that reform in this matter was urged on the Local Government Board by an interdepartmental committee in 1904. For the future it is recommended that all institutions which undertake the treatment of venereal diseases with the assistance of Government grants should keep and render available accurate aggregate statistics regarding these diseases, and that in particular a record should be kept of the number of patients for whom salvarsan or its substitutes is provided at the public expense.

The recommendations that will receive most attention are those dealing with measures for checking the spread of the diseases. They fall into two groups: First is dealt with that part which falls to the lot of the physician; secondly, that which is the province of all who have to do with the training of youth and the forming of healthy public opinion.

The report insists on the necessity for prompt and accurate diagnosis, to be followed by efficient treatment. The evidence of many witnesses is embodied in the reiterated statement of the report that these diseases, when taken in hand at their onset by capable medical practitioners, are curable in almost all cases—curable in the sense that the specific germs can be eradicated from the infected human organism. The proof of this lies in the fact that reinfection may occur.

Widespread use of modern scientific measures of diagnosis in which doctor and bacteriologist unite their efforts is urged. Existing laboratories—whether those of universities, colleges, voluntary hospitals, or public health authorities—should be brought into line for this work, and, where necessary, new laboratories established. These should be subsidized by grants from imperial funds to the extent of 75 per cent., the balance being found out of the local rates. In line with this recommendation is that dealing with the treatment of infected persons. Existing institutions should be encouraged to make special provision for the treatment of venereal diseases by providing sufficient beds for the urgent cases and outdoor clinics for the others; and it is urged that evening clinics should be established to facilitate the attendance of the working classes. The Commission is against special clinics for the purpose, on the ground that a separation of the patients would militate against resort to the clinics; they should be attached to and form part of the ordinary hospital accommodation of the country, and in particular the voluntary hospitals. At present there are hospitals which refuse such cases; it is even found that the charters of some prohibit, and that subscribers to others are averse to, their admission. These anomalies, it is considered,

should be rectified. The State should pay for these facilities in the same way as for the laboratories. The clinics should be available for all persons, and the patient should be free to attend at any clinic he pleases, not necessarily that in the district in which he resides. It is advised that if he is unwilling to go to a private doctor he should, even if able to pay, still be admitted for treatment at the public clinics. The organization of these clinics, it is considered, should be in the hands of the county councils and county boroughs, subject to the approval of the Local Government Board, and if the local authority will not provide the necessary treatment, that Board should be empowered to treat directly with the hospitals.

The Commission bases its recommendation of free and ample facilities for treatment on the necessity for combating the evil of unqualified treatment at the hands of chemists, herbalists, and quack "specialists." The denunciation of the evils that attend the exploitation of the infected by unqualified persons is emphatic and based on irrefutable evidence. The Commission went to the length of inviting the representative of one large group to give evidence, and in the words of the report "this evidence speaks for itself, and in our opinion effectually disposes of the claims of herbalists to be regarded as competent to treat venereal diseases." For the same reason the report urges that the recommendations of the Select Committee on Patent Medicines regarding the prohibition of all advertisements of remedies for venereal diseases should be put in force.

Difficulties bristle around the recommendation that persons who are not in necessitous circumstances should be admitted for treatment at public clinics. Their admission must be subject to such reasonable regulations as will prevent any serious abuse. The clinics are to be more than treatment centres; they are to admit all medical students and qualified practitioners for educational purposes, and will therefore improve the opportunities for acquiring knowledge of how to diagnose and treat these diseases.

Notification of the diseases was considered, but rejected as likely to be ineffective and dangerous. Ineffective because medical men would hesitate to disclose confidential information; and dangerous because it would tend to drive the disease underground into the hands of the charlatans. It is, however, thought that later on spread of public knowledge of the seriousness of the diseases may give rise to a public demand for some form of notification.

The Commission recommends that statutory recognition should be given to the principle that infectious venereal disease constitutes an incapacity for marriage. The process should be made available for all persons, however poor. Also it is recommended that the law should be amended so as to protect a medical practitioner who should deem it his duty to interfere actively in case of a proposed marriage of an infected person. Such a communication should be regarded as privileged. This proposal is supported by the high authority of the President of the Probate Division.

For the prevention of these diseases better education of the medical profession and of the public, particularly of the youth of the country, is advised. It is averred that the profession generally do not regard these diseases in a sufficiently serious light; that lack is to be corrected by fuller teaching in the medical schools, the potent influence of examination papers, and the facilities provided for special study in the new clinics. The Commission thinks that the State should provide a card to be handed by the doctor to his patient, setting out the grave dangers of the disease. The youth of the

country is to be instructed in regard to moral conduct as bearing upon sexual relation. "Such instruction should be based on moral principles and spiritual considerations, and should not be based only on the physical consequences of immoral conduct." Class instruction in elementary schools is negatived, but personal warning by the head teacher to the elder children, especially on their leaving school, is commended. The direct influence of the teachers in various grades of schools, colleges, and the universities is accentuated, the work of various forms of social effort for the young is commended and its extension on the same lines advised. Only the work of ministers of religion finds no place for remark in this crusade for righteousness. It will be seen from the trend of these recommendations that the Commissioners desire that the main effort of prevention should be directed to a widespread cultivation of personal control and the insistence that through this means alone can there be any real advantage to the health of the race.

We have endeavoured to indicate the main points in the report, and can refer to only two others. The one is the question of cost. It will be large, but the cost of the most complete laboratories and clinics would be a mere fleabite compared with the cost to the nation in sterility, infant death, child blindness and idiocy, parental weakness and exhaustion, nerve diseases and madness, and premature senility and death, that are the present effects of these diseases. As a financial investment the cost of the scheme would lead to the reaping of a national fortune. The second point is the sad reflection that so many of the recommendations of the Commission are no more than those which have been urged on the State by committees and commissions, and indeed passed into law in enactments that are now feeble by reason of lack of usage. Let us hope that the latent period of inertia will be overcome by this summation of stimuli.

THE TREATMENT AND EDUCATION OF DISABLED MEN.

THE Naval and Military War Pensions Act, 1915, which received the Royal Assent on November 10th, 1915, is entitled "An Act to make better provision as to the pensions, grants, and allowances made in respect of the present war to officers and men in the Naval and Military Service of His Majesty and their dependants, and the care of officers and men disabled in consequence of the present war, and for purposes connected therewith."

The first clause directs that a Statutory Committee of twenty-seven members shall be set up, consisting of nineteen representatives of the Crown and Government departments, two of the Soldiers' and Sailors' Families Association, and six, of whom some are to be women, appointed by the general council of the Royal Patriotic Fund Corporation. The Committee has been set up and held its first meeting on January 17th. The Prince of Wales is its chairman, and Mr. Cyril Jackson its salaried vice-chairman.

The Act directs that the council of every county and county borough, and every borough or urban district having a population of not less than 50,000 which so desires, shall set up a local committee constituted according to a scheme framed by the council. The Statutory Committee has drafted and issued a model scheme, which, in accordance with the Act, provides for the division of a county into districts, each with its district committee. A borough or

urban district having a population of not less than 20,000 may have its own district committee, and the metropolitan boroughs are to be separate districts. The council of the county, county borough, or district will appoint at least a majority of the local or district committee, but the scheme must provide for a substantial representation on both orders of committees of persons who have been performing within the area, either as members of the Soldiers' and Sailors' Families Association, or the Soldiers' and Sailors' Help Society, or otherwise, duties similar to those to be performed by the committees under the Act. At present the work of looking after disabled men is being carried on by the voluntary organizations, which, as the Marquis of Crewe stated in the House of Lords the other day, are doing it very well, and the Statutory Committee will maintain permanent relations with them.

At the first meeting of the Statutory Committee three subcommittees were appointed from among its members—the organization and general purposes, the finance, and the pensions, grants, and allowances committees. As the Parliamentary Secretary of the Local Government Board is to be *ex officio* a member of all these subcommittees, it is assumed that the intention is that the general administration of the Act shall be controlled by that Board.

Schemes made by a local committee must have the approval of the Statutory Committee, but the Prince of Wales, speaking as chairman of the Statutory Committee on February 1st, said that Parliament did not intend that any hard and fast limitations of a uniform character should be imposed upon the various local authorities. Just as counties and boroughs and other populous areas differed in many essential particulars, so it was not expected that their schemes for this experimental work should conform to any one pattern, but should present a considerable variety of features; they could be remodelled in the light of a larger experience. In concluding his speech the Prince said that every effort ought to be made to compensate by the truest form of neighbourly kindness for the deprivations caused to soldiers and sailors by their willingness to sacrifice life, health, and happiness at the call of their country.

One of the functions of the Statutory Committee and of the local committees is "to make provision for the care of disabled officers and men after they have left the service, including provision for their health, training, and employment," and the local and district committees, as well as the Statutory Committee, are to appoint special subcommittees, including representatives of employers and of labour, to make this provision. The Statutory Committee has already appointed a subcommittee for this purpose, and its composition is given in our parliamentary notes. Until a disabled officer or man has left the service his treatment and training are under the control of the War Office, and in a very large proportion of cases his ultimate fate in regard to his power to earn his own living in whole or in part, and so again becoming a useful member of the community, will by that time have been decided. The committees set up under the Naval and Military War Pensions Act will have to deal with men who, in the opinion of the army medical authorities, cannot again be fit for military service. The main duty of the statutory and local committees in regard to such men will be to train them and find employment for them. According to the figures given by Lord Crewe on February 29th, out of a total of 23,000 men whose names were received by the Board

of Trade from the Admiralty and the War Office between June, 1915, and January, 1916, 13,000 had applied to the Labour Exchanges for help in finding employment. In round numbers employment had been found for 5,400; 1,400 were still on the register, but close on 6,000 had cancelled their applications, either because they were not fit for any serious employment or because they had found work otherwise.

In his speech on St. David's Day, which we briefly reported last week, Mr. Lynn Thomas said that he had received a letter from a well known surgeon of a neutral country, who, after visiting the lines of two of the belligerents—apparently the German and the French—had said that general surgery had had little to learn from the present war, except on two points: the one was the value of the prophylactic use of anti-tetanus serum, and the other the importance of orthopaedic treatment of wounded men. Some idea of the magnitude of the problem is afforded by the statement of the Prince of Wales on February 1st, when, in his speech to the Statutory Committee, he said that the total casualties of all ranks in the South African war were 44,876, while the total casualties of all ranks in the present war numbered at that time 549,467. A certain proportion of these will be incapacitated by the nature of their wounds from doing any useful labour; others will, at the best, be able to do very little; but the proportion of those who have suffered wounds of the limbs, and by early and adequate orthopaedic treatment can be put in a position to be useful workers, may, it is reasonable to hope, prove to be large. The treatment, however, must be instituted early, must be inspired by orthopaedic experience, and must be continuous. We have reason to believe that the army medical authorities are alive to the importance of early and thorough treatment, but the principle must be grasped by the public also, in order that the committees under the Pensions Act may be adequately provided with funds to ensure that the orthopaedic treatment and education of men discharged from the army or navy shall be both adequate and continuous. From this point of view alone there is a very useful field of work for the Statutory Committee and the local and district committees. The sooner it is taken in hand the better.

ANTISEPTIC ACTION OF THE CHLORAMINE GROUP.

At the meeting of the Royal Society on March 2nd a paper on the antiseptic action of substances of the chloramine group was presented by Professor J. B. Cohen, F.R.S., Dr. H. D. Dakin, M. Daufresne, and Dr. J. Kenyon. The probability that the formation from proteins of substances containing halogen was an intermediate stage in the germicidal action of hypochlorites was considered to make it desirable to investigate systematically a number of substances containing the (NCl) group. Among the substances investigated the most promising was the group of sulphochloramides as prepared by Chattaway. The main results of the investigation were stated to be as follows: (1) Almost all the substances examined containing the (NCl) group possessed very strong germicidal action. (2) The presence in the molecule of more than one (NCl) group did not confer any marked increase in germicidal power. (3) The germicidal action of many of these chloramine compounds was, molecule for molecule, greater than that of sodium hypochlorite. (4) Substitution in the nucleus of aromatic chloramines by Cl, Br, I, CH₃, C₂H₅, or NO₂ groups did not lead to any very great increase in germicidal activity. More commonly there was a moderate diminution. (5) The chloramine derivatives of naphthalene and other

dicyclic compounds of sulphochloramide type closely resembled simpler aromatic chloramines in germicidal action. (6) The few bromamines examined showed a slightly lower germicidal action than the corresponding chloramines, but sodium sulphobromamides were much more active than sodium hypobromite. (7) Derivatives of proteins prepared by the action of sodium hypochlorite and containing (NCl) groups were strongly germicidal. Blood serum inhibited their germicidal action to much the same extent as it did that of sodium hypochlorite or the aromatic chloramines. Among the above products para-toluene-sodium-sulphochloramide was selected as being on the whole most suitable for practical use. It was easily and cheaply made; it was relatively non-irritating to wounds; it was non-toxic and very soluble in water, and might be kept unchanged both in the solid state and in solution for a long period. A table was appended giving bacteriological results obtained from about fifty compounds of this class. A paper giving an account of the nature and practical uses of this substance, para-toluene-sodium-sulphochloramide, was published by Dr. Dakin, Professor Cohen, and Dr. Kenyon in the BRITISH MEDICAL JOURNAL of January 29th (p. 161), where its preparation, cost, and mode of action were also considered. Unfortunately, the anticipation that it could at the present time be cheaply produced does not seem to have been fulfilled. It is stated that, owing to the use of chloramine bodies in the making of explosives, materials ordinarily obtained as by-products have now to be made. The substance has been placed on the market under the name of "tolamine," because the word chloramine had already been appropriated by an American firm of druggists for a totally different kind of medicine.

PETROL FOR DOCTORS.

THE Medico-Political Committee of the British Medical Association has for some time been giving anxious consideration to the difficulties experienced, and likely to be increasingly experienced, by doctors in obtaining petrol for their cars or motor bicycles. Several representations have been made to the Board of Trade on the subject. A special meeting of the committee was held on March 8th to confer with representatives of certain Government departments concerned with the larger question of the supply of petrol for Government requirements generally and for the civil community. The conference, which was necessarily confidential, dealt with several matters of great importance. The Government representatives indicated the necessity of reliable information being rapidly forthcoming as to the quantity of petrol actually needed month by month by the medical profession in the different parts of the country if any effective action were to be possible to the Government for arranging, as was desired, that doctors should be secured their minimum requirements for fulfilling their duties to the civil community. Certain immediate steps were decided on with a view to obtaining that information forthwith. It was stated that the Government departments entrusted with the question were anxious that the needs of the medical profession should receive special attention in any scheme that might be evolved for the distribution of petrol under any new conditions that might be set up. The Committee, whilst realizing from the discussion the great practical difficulties that will have to be solved by any Government scheme for the community of the kind that seems to be contemplated, feels assured that the special case of the medical profession is being fully recognized in the responsible quarters, and the Committee will not cease to keep in close touch with any further developments. The steps above mentioned will probably include the issue of certain inquiries to medical practitioners throughout the country, and it is hoped that in the interests of each individual, and of the profession as a whole, these questions, when received, will be answered fully and without any delay.

WITH THE MONTENEGRIN ARMY IN THE FIRST
BALKAN WAR.

A MEMBER of the Austrian Red Cross, Dr. Hermann von Schroetter, has lately published a book giving an account of his experiences in the Montenegrin campaign against Turkey in the first Balkan war. Though certain passages in his book show that even at this date the political relations between Montenegro and Austria were somewhat strained, Dr. Schroetter gives a most sympathetic account of the valiant little Montenegrin army. It must indeed be strange for a man who shared the vicissitudes of the Montenegrins in their heroic battles with the Turks to find his own country only a few years later at war with Montenegro. The conditions under which the Montenegrins fought and suffered in the first Balkan war were, no doubt, very similar to those obtaining in the present war, and Dr. Schroetter depicts the heroic atmosphere of Montenegro in stern but sympathetic colours. Not only was every male from 15 to 70 a soldier, but the women took part in the fighting, following their men even into action, as well as trudging day by day under heavy burdens of food and ammunition. In the battle of Kiri many women were wounded, and seven were admitted to Dr. Schroetter's field hospital. They were cared for in the same ward as the wounded men, and helped to keep up their courage, vying with them in bearing pain with fortitude. Again and again does Dr. Schroetter speak of the hardihood of these mountaineers, with whom it was a point of honour not to break down by so much as a moan, were their pain, hunger, and thirst never so great. But it was not altogether easy to treat them. They did not cry out for anaesthetics for operations big and small, but they often stoutly resisted amputations—not for fear of pain, but of the resulting mutilation, which was regarded as a disgrace by the patient's relatives as well as by himself. One of the wounded, a girl of 18, acquired the nickname of "the wild cat," for she would not at first allow her three wounds to be dressed. Naturally Dr. Schroetter found only the most elementary surgical equipment of use. Stumbling in the dark among heaps of wounded lying in a single room, he found he had left behind the most necessary adjunct to first aid—a pocket electric torch. His account of the wounds he observed tallies more with the experiences of the South African war than with those of the present war, probably because the fighting with the Turks soon assumed the character of guerilla warfare, the majority of the wounds being inflicted at long range by rifle bullets.

INJURIES AND DISEASES OF AVIATION.

FROM the medical point of view the Flying Service is not quite like any other, owing to the special demands it makes on those who take it up, and the special lesions to which it may give rise. Staff Surgeon H. V. Wells, R.N., has drawn attention¹ to these peculiarities, quoting a number of examples to illustrate them. These accidents of aviation are mainly those due to sudden stoppage of the aeroplane, when, owing to some accident, it falls headlong to the ground, or by some loss of control lands at too sharp an angle. Here the aviator is thrown violently forwards as the machine hits the ground: he is usually strapped firmly to his seat, and so his head and neck are jerked forwards, with the danger of his striking some portion of the structure in front of him and injuring his forehead, or of straining the muscles of his neck, or even of fracturing a vertebra without displacement. It is thought that an abdominal belt should always be used to hold the aviator in his seat; the belt should have a quick release apparatus, and be fixed to the aeroplane rather than to the seat itself. In some instances the aviator has succumbed to profound shock without any obvious grave injuries after a fall; Staff Surgeon Wells suspects that there are numerous minor internal haemorrhages in these cases,

¹ *Journal of the Royal Naval Medical Service*, London, 1915, i, 55, and 1916, ii, 65.

but it would be interesting to know whether fat-embolism is not the actual cause of death here, whether bones are broken or not. It is known that mere concussion of the bones of experimental animals can produce fat-embolism. In a few instances eye injuries have resulted from the working loose of some nut or bolt in a tractor aeroplane, and the blowing of the piece of metal backwards, in the draught of the screw, into the aviator's face. Frost-bite of the face has occurred after aviation at high altitudes; partial anaesthetization by the vapour of escaping petrol used to be common, before a tap was fitted enabling the petrol supply to be controlled from the aviator's seat. The exhaust gases from the motor have been known to reach the pilot in quantities large enough to cause headache and sleepiness. So far as the selection of candidates for aviation is concerned, several interesting points have been brought to light by recent experience. Some pupils are found on trial to have no genius for aviation; they are not lacking in nerve, but cannot acquire the involuntary spontaneous co-ordination of hand and eye that is indispensable for the aviator, and are never comfortable when flying. The name suggested for this condition of mind is "aerosthenia," surely a misprint for "aerasthenia." It is an immediate disqualification for aviation. So far as age is concerned, it is now found that boys of 18 or 19 are not too young to learn to fly; the age of 30 is the limit at which pupils should be taken, except in rare instances. Pupils who have to wear glasses should be rejected; an interesting case quoted is that of a pupil with full vision in each eye separately and with both eyes together, who could only land with difficulty and with one eye closed. He was found to have "a concomitant squint," preventing him from judging his landings. It is essential, too, that the aviator should have free movements in his knee and ankle joints, otherwise he will lack delicacy in his control of the rudder bar, a matter of supreme importance. During 1912 and 1913 researches were made into the effects of flying on the pulse-rate and blood pressure of the aviator. The results were inconclusive; nearly all the cigarette smokers seemed to have rapid pulses, as was, perhaps, to have been expected. Quite recently this question has been gone into again by Dr. G. Ferry,² who finds that his own pulse becomes small and rapid in proportion as he ascends, becoming slower with the descent. So far as the arterial blood pressure is concerned, the maximum pressure varies during ascent, generally falling a little, the minimum pressure falling 10 or 20 millimetres of mercury. During the descent the maximum arterial pressure usually falls and the minimum pressure increases. Speaking generally, the arterial pressure is lowered after a flight. Dr. Ferry concludes that aviators should be chosen from those who have no disease of the circulatory system.

MALARIA ON SHIPBOARD.

STAFF SURGEON LESLIE M. MORRIS has described in an interesting paper published in the *Journal of the Royal Naval Medical Service* (January, 1916), the experiences of the *Hermione* and the *Bristol*, when employed in the river off Tampico during the Mexican revolution, from December, 1913, to July, 1914. There are lagoons and marshes on both sides of the river, and the district is very malarious from May to January. The crews of both ships were attacked by malaria in spite of the precautions taken. The *Hermione*, which had a complement of 325, suffered two outbreaks; the first cases, beginning twelve days after arrival, were contracted on the first night in the river; when *Anopheles* swarmed on board and the precautions which could be taken were inadequate. It produced 51 cases; the second, which began after the first rains in May, produced 55. The type of infection was tertian benign, and subtertian or malignant in a ratio of 4 to 1. The treatment adopted was to give at the onset 15 grains of

² *La Presse médicale*, Paris, February 14th, 1916, p. 65.

quinine by the mouth with 3 grains of calomel; then 10 grains of quinine thrice a day for five days, and then 10 grains twice a day for another five days. This was followed by a course of 5 grains thrice a day for three weeks, and afterwards a weekly dose of 10 grains every Sunday for three months. If a case did not react satisfactorily, if gastro-intestinal symptoms were troublesome, or if the temperature was over 103° the quinine was given by intramuscular injection; 1 gram of the bihydrochloride in 1 c.cm. of sterile water. The main prophylactic measure was the use of mosquito-proof brass wire gauze netting, as used in Panama, over the ports and doors, while muslin was used to close a number of other openings. The *Bristol*, which arrived at Tampico on June 9th, 1914, was provided with a supply of mosquito-proof copper wire fittings made and adapted at Portsmouth, and there was a quantity of wide mesh muslin in store. The men received a dose of 10 grains of quinine on alternate evenings, and all were required to be between decks and behind screens by 6 p.m. Watch-keepers and signalmen on deck were supplied with helmets having muslin veils, wore gloves, and had their feet and ankles protected, and no lights were permitted on the upper deck at night. Nevertheless, on the thirteenth day cases of malaria began to occur, at first among the ward-room domestics and cooks from the upper deck galleys; next followed the younger members of the ship's company from the after-part of the ship. The *Bristol* left Tampico on June 29th, and the number of fresh cases decreased rapidly after she had been away for two weeks. Altogether, there were 95 cases out of a ship's company of 375. When war was declared the ship was free from malaria, but relapses occurred in September, due, it was thought, to the hard work entailed by constant steaming and coaling off the coast of Brazil in extreme heat. Another series of relapses occurred when the ship was employed for four months in the Magellan Straits searching for the *Dresden*. They were attributed to the cold weather and extremes of temperature experienced. None occurred after the ship proceeded to Gibraltar in May, 1915. Staff Surgeon Morris says that the efficient screening of a ship presents difficulties which can only be overcome with the intelligent help of all officers and men, and that to gain the help of the ship's company lectures are necessary. He advises that ships proceeding to known malarial localities should be previously fitted with gauze-covered doors and frames for hatches, scuttles, and air supply inlets. Coverings for other openings can be quickly improvised if reserve supplies of gauze and open-mesh muslin are available. He has no doubt as to the value of the regular administration of quinine as a prophylactic. He states that in the German ships, in a Dutch ship, and in some of the American ships 1 gram was given every fourth day. Another plan which he considers good was to give 10 grains for three consecutive evenings, followed by two days without quinine. Only one officer of the two ships contracted malaria, and he attributes their immunity to the fact that nets were carefully used and quinine regularly taken. He also considers that a moderate amount of alcohol taken after sunset is beneficial in aiding to ward off malarial infection, and suggests that it would be a good plan to issue the rum ration after evening quarters in malarial localities when men are taking quinine.

SHORTAGE OF DRUGS IN AUSTRIA.

Last autumn the representatives of the Pharmacological and Pharmacognostical Institute of the University of Vienna issued a warning notice as to the shortage of certain drugs. It appears that *Digitalis purpurea* was mainly obtained from Germany, which had prohibited its export. It was urged that other varieties of digitalis and strophanthus should be used instead. The supply of camphor was so short that it was necessary to confine its

prescription to internal use. The supply of ipecacuanha and senega had been cut off, and it was therefore advisable to use quillaia bark and saponaria root as expectorants. There was a great shortage of purgatives, as rhubarb root, senna, cascara, aloes, and jalap were all imported drugs, and castor oil, which had been imported from France and Italy, could no longer be obtained in Austria. The best native alternatives for these purgatives were said to be the phenolphthalein preparations and frangula, which grows plentifully in Austria, and is reputed to be as effective as cascara. As the Austrian rhubarb root contains only half the amount of active principle found in the Chinese, the dose must be increased proportionally. The supply of atropine, scopolamine, apomorphine, physostigmine, and hydrastis were all short; in the case of the last named the synthetic hydrastis might be substituted. The antipyretics, pyramidon, antipyrin, phenacetin, and antifebrin, were all prepared outside Austria, and were prevented from reaching the country by the prohibition of exports (presumably from Germany). The same was the case with aspirin and other salicyl preparations. Owing to the shortage of quinine it was necessary to confine its use to malaria. The importation of sulphur and iodine was no longer feasible; substitutes recommended as disinfectants were a solution of bromine in chloroform or benzene, and a 5 per cent. alcoholic solution of tannic acid. Very little balsam of Peru was left, and its place had, therefore, largely to be taken by ichthyol preparations.

THE ENROLMENT FORM A CERTIFICATE OF ELIGIBILITY FOR HOME MILITARY POSTS.

We are able to publish in the SUPPLEMENT this week, page 42, an Army Council instruction (24/Gen. No./4749, A.M.D. 1) which will be read with much interest by many members of the profession who are anxious to serve the country at this time but have not yet been employed. The notice issued by the Medical Department of the War Office on September 3rd, 1915 (SUPPLEMENT, September 18th, 1915, p. 130), advanced the age of medical men for general service at home and abroad to 45, but made it plain that no man under the age of 45 years would be employed in home military service. Recently the Central Medical War Committee represented to the War Office that it was desirable that there should be exceptions to this rule; it was, for instance, pointed out that a man under 45 years of age who had enrolled with the Committee for general service in the medical sense—that is, for work at home or abroad—might be employed at home on temporary duty pending the time when he may be required for full service. The Army Council instruction dated March 2nd accepts this position, and definitely states that medical officers who have enrolled with the Central Medical War Committee, or the Scottish Medical Service Emergency Committee, for service with the army and are in possession of a certificate may be considered eligible for army duty irrespective of their age. This means that a man under 45 who is enrolled with the Committee will be eligible for service in such posts as civil medical practitioner or medical officer examining recruits whilst he still remains at home in private practice.

Most of the members of the Royal Commission on Venereal Diseases have accepted an invitation to join the National Council for Combating Venereal Diseases. There is little doubt, from past experience, that unless there is some independent society capable of stimulating the powers that be, and repeating that stimulus, the most ably drafted report and the most excellent recommendations of a Royal Commission will most probably not be carried out. It is therefore to be hoped that influential members of the profession will join the National Council and help Sir Thomas Barlow and those who are associated with him in its work.

Medical Notes in Parliament.

Retrenchment.—The Chancellor of the Exchequer stated on March 7th that early effect would be given to the recommendations in the report of the Retrenchment Committee as far as it was found possible to adopt them. The Treasury was considering the terms of the necessary communications to the public departments on the various questions raised.

Tuberculosis Order.—The Parliamentary Secretary to the Board of Agriculture stated on March 7th that the Board has decided to maintain the suspension of the Tuberculosis Order, 1914, until after the war. The question of modifying the Order had been considered, but it did not lend itself to modification within the lines of the policy laid down in the manner suggested by the City Council.

Cocaine in India.—On March 2nd the Secretary of State for India stated, in reply to Sir J. D. Rees, that cocaine had in the past been smuggled into India by Austrian and German and also by other steamship lines. The cocaine habit, in a more or less furtive form, existed in Indian seaport towns, and in a less degree in the largest inland cities; but, so far as information went, it appeared to be unconnected with the opium habit or with measures taken to suppress the latter.

War.

Disablement Subcommittee of Statutory Pensions Committee.—The Naval and Military War Pensions Act, Section 3, Subsection (3) directs the Statutory Committee appointed under the Act to appoint a special subcommittee, including representatives of employers and labour, for the purpose of making provision for the care of disabled officers and men. The Parliamentary Secretary to the Local Government Board stated, in reply to Mr. Butcher on March 2nd, that the committee as then constituted was as follows, but a few members whose consent had not been obtained might be added:

Ex-officio members: H.R.H. the Prince of Wales, as chairman of the Statutory Committee; Mr. Cyril Jackson, as vice-chairman of the Statutory Committee; Right Hon. W. Hayes Fisher, M.P.
Soldiers' and Sailors' Help Society: Lord Chylesmore.
Officers' Families Association: Lady Roberts.
Admiralty: Admiral Sir Wilmot H. Fawkes, G.C.B., K.C.V.O.
Army Council: Mr. B. B. Cubitt, C.B.
National Insurance Joint Committee: Mr. D. J. Shackleton.
Labour Exchanges Dept. (Board of Trade): Mr. J. S. Nicholson.
Local Government Board: Mr. A. V. Symonds.
Board of Agriculture: Mr. F. L. C. Ploud.
Representatives of Labour: Right Hon. G. N. Barnes, M.P., Mr. Harry Gosling, Mr. Will Thorne, M.P., Mr. Herbert Smith, Mr. W. Mullins, Mr. J. E. Williams.
Representing the Co-operative Interest: Mr. Lander, Mr. Harry May.

Lieutenant-Colonel (R.A.M.C.) Sir Alfred Pearce Gould, K.C.V.O., Sir John Cowan, Sir Archibald McLunes Shaw, Mr. Patrick O'Brien, M.P., The Right Hon. R. Thompson, M.P., Mr. L. A. Martin, Mr. Harris Spencer, Dr. William Garnett (Educational Adviser, L.C.C.).

Mr. Hayes Fisher added, in reply to Mr. Hogge, that one of the first questions for the consideration of the Committee would be whether separate committees should be set up for the various nationalities of the United Kingdom.

Medical Students.—In reply to Mr. Pringle, on March 2nd, Mr. Tennant restated the position with regard to medical students as follows:

Medical students in their fourth or fifth years of study and those in their third year of study whose examination takes place during the winter session must either attest under the group system or become liable to the Military Service Act. The fourth and fifth year students will not be called up, and if the third year students pass their examination they also will not be called up, but if they fail they will be called up. Students who have not attested under the group system, and who in consequence become liable to the Military Service Act, must appeal to the local tribunal if they desire exemption.

Total Casualties.—The Prime Minister stated on March 1st that it was not advisable to make public the totals of casualties at regular intervals; figures would be given from time to time as the military situation might permit.

Wounded Prisoners in Switzerland.—On March 7th Mr. Malcolm asked the Prime Minister whether there were at the present time about 1,600 French and about 850

German prisoners of war suffering from specified diseases interned in sanatoriums in Switzerland, and whether the Swiss Government had offered to receive British prisoners similarly afflicted. The Prime Minister in his answer confirmed the statistics. Though the British Government had received no official invitation from the Swiss Government to send wounded prisoners to Switzerland in the event of an agreement being arrived at with the German Government, it was understood that such a course would be agreeable to the Swiss Government. The British Government was favourable to the proposal, and action was being taken in the matter.

Tuberculous Soldiers.—Mr. Tennant has informed Mr. Astor that the total number of soldiers invalidated for tuberculosis dealt with by the Chelsea Boards in 1915 was 2,770. Cases of pulmonary tuberculosis were not separately recorded. Pensions were awarded in 1,641 cases and the claims were not accepted in 1,129.

Hospital Stoppages.—Mr. Forster (Financial Secretary to the War Office) stated on March 7th that a hospital stoppage of 7d. a day, or such less sum as the soldier's commanding officer might determine, was deducted when men were in hospital in circumstances which in the discretion of the commanding officer were held to justify the deduction. This discretion should prevent any case of real hardship.

Cerebro-spinal Meningitis.—In reply to a question on March 7th as to the number of cases of cerebro-spinal meningitis among soldiers in the district of the Portsmouth Command, Mr. Tennant said:

The figure for the Portsmouth District Medical Administrative Area, which includes the Portsmouth Garrison, Isle of Wight, Winchester Area, Dorsetshire Area, and Portland Defences, including Weymouth, is 31. The number of deaths has been 8. Special measures are carried out, under an organization set up fifteen months ago, to guard against spread of the disease. These consist of isolation of the patient, disinfection of the patient's clothing, etc., segregation and special medical treatment of contacts and carriers.

Colonial Allowances.—Mr. Forster (Financial Secretary, War Office) stated on March 1st, in reply to Mr. Swift MacNeill, that colonial allowance is a special allowance designed to meet the extra expense thrown upon officers of the British army by service in Egypt and certain other places under peace conditions. The question of its discontinuance during war in places in which it was drawn in peace presented difficulties, but was under consideration. He regretted that it could not be extended to officers serving at Salonika.

Non-Poisonous Dope.—In reply to Mr. Rowlands, Mr. Brace said on March 7th that the main difficulty in the way of the adoption of non-poisonous dope for aircraft was that one of the essential ingredients was not produced commercially in this country at present. The conference between the War Office and the Admiralty considered the methods by which the supply of the ingredient could be increased, and efforts were being made to arrange for this. The Admiralty was continuing its experiments.

Military Service Act.—Many questions have been asked with regard to recruiting and the Medical Service Act.

Not a few have dealt with the constitution and procedure of local tribunals, some of them raising points relating to individuals. In reply to one question, the President of the Local Government Board said on March 7th that the tribunals had a difficult and ungrateful task; their duty was to administer the Act and the regulations to the best of their ability, and he believed that they were generally fulfilling that duty faithfully and honestly. If they came to a decision thought to be improper, the aggrieved party had the right to appeal.

On March 7th Mr. Watt asked whether men who had been declared medically unfit since August 14th, 1915, and had been again summoned, could have the matter tried in the civil courts. Mr. Tennant, in reply, said that he thought it might be assumed that it was the desire of all eligible persons to assist the administration of the Military Service Act and not to hamper it. A man who had a certificate of rejection in proper form, signed by the proper authority, was excepted from the provisions of the Act. Men who had not so offered themselves and been rejected since August 14th would be held to serve under the terms of the Act.

Mr. Tennant stated on March 7th that exactly the same standard was observed in respect of all classes of men coming before the army medical authorities for examination, whether they reported themselves for service under the Military Service Act or came forward voluntarily. Recruits were now, and had for some time past been, graded in different categories according to their suitability for various forms of military service. Otherwise the standard was exactly the same as three months ago.

THE WAR.

THIGH CASES.

(From a Correspondent in Northern France.)

COMPOUND fracture of the femur, from the point of view of the evacuation of such cases, was the subject chosen for discussion at the periodical meeting at the Australian Hospital on January 22nd, and its staff secured the representation not only of base hospitals but of all units dealing with these cases, between the time of their occurrence and the moment they are landed at a British port. The other visitors included Mr. Robert Jones of Liverpool and Mr. Lynn Thomas, C.B., of Cardiff, who were introduced to the meeting by Surgeon-General Sawyer.

The first speaker, a battalion M.O., said that all medical work in the fire trenches had to be done under the most adverse conditions. The liquid mud was sometimes so deep that if a wounded man fell into it he was liable to be suffocated. In his own area, moreover, the fire trenches were so battered that only after dark could he get into them. He had therefore commonly to leave first-aid work to be done by his orderlies, whom he distributed at intervals along the section of the trench occupied by his battalion. His instructions to them in regard to thigh cases were to aim at combating shock by administering a dose of morphine, making the patient comfortable by means of sandbags, and covering him with an overcoat and a waterproof sheet. The fracture was treated by bandaging the patient to one of the footboards running along the bottom of the trench and then placing this and the patient on the fire step or elsewhere so as to be as much as possible out of the way of the fighting men in order to avoid accidental disturbance. It was not easy, for the front trenches were necessarily very narrow. To keep the patient above water level it was sometimes necessary to drive in piles. As soon as darkness arrived four stretcher-bearers advanced, lifted the patient on his board out of the trench over the top of the parapet, and carried him to a wheeled stretcher-carrier, though when the intervening ground was very rough and muddy it was found best to carry the stretcher on the shoulder. Arrived at the regimental aid post a Liston splint was substituted for the footboard, and the patient sent on to the advanced dressing stations in the bottom berth of an ambulance.

The next speaker (a field ambulance M.O.) said that cases usually reached them between 10 p.m. and 3 a.m., and with their clothes caked in mud. The first aim was to try to get the patient warm by changing his clothes—putting him on a dry stretcher, and keeping the room heated. The chief trouble about a thigh case was the damage to the soft tissues; it extended far beyond what superficial appearances suggested. Limbs which seemed about normal when they first arrived were often found enormously swollen by the morning. He found the first Page splints satisfactory to use because they allowed free access to the wound without disturbing the patient, and nowhere constricted the limb. A modified form recently supplied tended to buckle, and was otherwise less satisfactory. If the fracture were very high he preferred an interrupted Liston. To clean the wound he poured in hydrogen peroxide solution, which brought to the surface foreign bodies such as clothing. He removed bits of bone only if quite loose. Anaesthetics he rarely found necessary. Compound fracture of the thigh seemed to result in a kind of numbness, and if the patient had had a dose of morphine he generally slept through the dressing. If necessary he enlarged the wound sufficiently to allow the easy insertion of a drainage tube. The avoidance of constriction above the wound was a point of primary importance.

A motor ambulance convoy officer said he always chose the lower tier for thigh cases; they were thus subjected to less jolting and were within easier reach of the orderly. A Page splint was satisfactory provided it were fastened to the stretcher.

A casualty clearing station officer said that thigh cases arrived at his unit splinted in a variety of ways; sometimes, for instance, by a rifle, sometimes by a Liston splint. In default of some definite reason for immediate interference, such as haemorrhage, the usual practice was

to leave the patient undisturbed for some hours, except that he was put on a dry stretcher and blankets. The speaker preferred to give an anaesthetic when cleaning up the wound, but now used stovaine anaesthesia, as he found that open ether was generally followed by chest trouble. To secure free drainage he made an incision between two and three inches long, and drenched the wound with normal saline. All free material was carefully removed, but nothing that seemed firmly attached to bone. In the way of splints he preferred a modified Thomas knee splint unless the fracture was high up; if so he used a McIntyre. Cases in which the main vessels were injured or gas gangrene was already present should, he thought, be submitted to immediate amputation. In his unit thigh cases were usually kept a week before they were sent to the base; meantime the wound was cleaned three times daily with normal saline and hydrogen peroxide. The mortality in these cases was between 10 and 12 per cent.

A second casualty clearing station M.O. said that they too generally left a thigh case alone for twelve hours or so before undertaking any surgical cleansing, for the shock was generally considerable. If operative measures were undertaken an anaesthetic was invariably given. Their idea, however, was that it was at the base hospital that the real work should be done; patients were therefore got away as early as possible. Generally, a modified Thomas knee-splint was used, unless the fracture was very high up. He had seen plaster-of-Paris used, but thought casualty clearing stations were not places for its employment.

At this point Surgeon-General Sawyer interposed a remark to the effect that the French, who attach great importance to immobilization in these cases, depended largely on plaster-of-Paris at their hospital at Châlons, and thought the English did not make sufficient use of it.

A train M.O. said that with the ambulance trains now in use it was possible to avoid taking a thigh case off the stretcher. The condition in which the patients generally reached the train reflected great credit on medical officers in the field. Sometimes, however, the labels did not state whether the patient had received morphine, and this created difficulties. Generally the cases required very little treatment in the train, and the splints and dressings need not be touched. But the work could not be expected to be always equally perfect. During heavy fighting, such as that round Loos, cases sometimes reached the trains inadequately splinted. In train work the use of sandbags was very helpful. There had been some curious cases in which patients who seemed to be doing very well died suddenly on the journey without apparent cause.

Another train M.O. said he would like to have more notes sent with the cases. It was essential, for instance, to know if the patient had recently received morphine. The sending down of the more serious cases should be deferred as long as possible. Provided the splint kept the fracture at rest it could hardly, from a train point of view, be too simple in construction.

A base hospital M.O. thought that all thigh cases should be incised and drained before dispatch. He generally used a Balkan suspension apparatus, but a Thomas splint was equally good. If the fracture was very high up he used vertical extension. When the patient was fit to be sent home he placed the limb in a Boulogne box splint. Hydrogen peroxide he found decidedly useful. There was a tendency to overlook the fact that sepsis was the principal source of danger in these cases.

A second base hospital M.O. said the cases were always put on a Bradford frame, which had been introduced at his hospital by some Harvard medical officers. It facilitated all nursing and allied work, and the patient did not from first to last require to be removed from it.

A third base hospital M.O. said the condition in which these cases arrived varied a great deal in respect of efficiency of treatment. At his hospital the practice was to have an x-ray picture taken forthwith and then make any necessary incisions. He made quite small incisions and covered the wounds with gauze.

Another officer from the same hospital said that all fractures in the upper third were now treated on a Bryan bed, and those in the lower two-thirds on a Thomas knee splint, furnished with a perforated zinc instead of a

bandage gutter. It was desirable that the patient should be able to move himself freely. This was impossible if a plaster-of-Paris splint were used.

An embarkation M.O. said that when cases were fitted with wide abduction splints it was difficult to get them from the ambulance on to the ship. For shipping purposes the Bradford frame was excellent. Full labelling of patients was very necessary.

A battalion M.O. here interposed a suggestion that the labels used should be so large that notes could be made upon them at every stage from the trenches to a home hospital.

A hospital ship M.O. said that the Bradford frame was excellent from his point of view. Cases sometimes arrived fitted with splints so large that they had to be kept on deck instead of placed in a cot. As a patient might be on board for as long as sixty hours it was necessary that they should be well and comfortably splinted, as also well dressed before embarkation. The staff of a hospital ship was necessarily limited and could not readily undertake the redressing of many cases. The cases were landed by lowering them on to a raft and thence raising them to the quay by a crane. This was a further reason for preferring simple splints, for if the splints were very large and complicated, prompt unloading was difficult.

A base consultant surgeon expressed a belief that the Thomas knee splint in ordinary cases and the Thomas abduction frame in high-up cases were greatly preferable to all others. If freedom of movement were desired it could be secured by suspending the end of the splint from the ceiling. But in the early stages, at any rate, all movement was undesirable, the constitutional shock in these cases being very great. Cases in which large incisions had been made did b st.

Major ROBERT JONES said that those who, like himself, did their war work at home hospitals, did not, perhaps, fully appreciate the difficulties with which M.O.'s at the front had to contend. In the circumstances the results obtained seemed to him splendid. Some years ago, when the Manchester Ship Canal was being constructed, he had often had to deal with injuries which closely resembled shell wounds and found it a great advantage to dispense with the use of anaesthetics. They were not so essential in such cases as was sometimes thought, for sufferers from serious injuries did not feel a great deal of pain. When amputation had to be performed the modified circular incision should be preferred and the skin drawn back as far as it possibly could be, in order to secure a stump to which an artificial limb could easily be fitted. In fractures of the upper third, abduction of the limb was essential; unless the thigh were kept well out the result could not be satisfactory. During transport the abduction could be temporarily disused. Most of the splints he had so far seen were modifications of the Thomas.

The proceedings then concluded after a few observations from Mr. LYNN THOMAS and other visitors and the adoption of a vote of thanks to the officers of the Australian Hospital, on the proposal of Surgeon-General SAWYER.

NEUROLOGICAL NOTES.

In a paper written at the request of the Medical Society of Berlin,¹ Hermann Oppenheim stated that he hardly ever saw a quite recent lesion of the nervous system incurred in the fighting line.

Brain.

He was greatly surprised by the rarity of late abscess after lesions of the brain, and he disagreed with Marburg's statement that abscess was an inevitable sequel to a wound of the brain in which the bullet remained. The following features of brain lesions were of special interest: (1) In many cases the severity of the wound was seemingly out of all proportion to the insignificance of the symptoms, notably the local symptoms. (2) On the other hand, in certain cases in which the bullet had injured a number of centres and paths of conduction in its course through the brain, the number and variety of the local symptoms were most striking. (3) Cortical symptoms were most prominent when the wounds of the head were tangential and superficial. (4) The number of cases in which the symptoms were bilateral was very great. One of the most

striking phenomena was cerebral cortical paraplegia. While the motor symptoms seemed to follow definite laws, the behaviour of the sensory symptoms was apparently erratic. (5) The complex variations in the visual symptoms could be traced to the great number of points in the brain at which the optical connexions and centres could be wounded. Among the rare forms of central optical disturbances was hemianopsia inferior, which he had not seen before. (6) Many cases presented cerebral and labyrinthine symptoms, which pointed to a lesion far from the site of the bullet wound. In many instances this paradox could be explained by the presence of extensive fissures of the skull. There seemed to be a form of nystagmus independent of any lesion of the cerebellum and its connexions. (7) The proportion of recoveries was extraordinarily high, and many a patient had been sent back to the front. (8) In not a small proportion of cases organic lesions were combined with functional disturbances.

Cord.

The most common sequel to bullet wound of the cord was localized necrosis, which was much more frequent than haemorrhage into the cord. A by no means rare condition, though it had scarcely been previously observed as a sequel to injury to the cord in war, was Brown-Séquard's paralysis with homolateral anaesthesia. This condition was probably due to a bullet having struck chiefly the motor fibres on one side of the cord and the sensory fibres on the other. Most of the lesions of the cord were transverse, but in a few the projectile passed longitudinally, wounding the cord for a considerable distance. Lesions in the cervical region were often combined with injury to the plexus, which greatly diminished the prospects of successful operation. In a few cases the injury to the cord was so slight that the only evidence of its involvement was Babinski's sign, paraesthesia of the area supplied by the ulnar nerve, or disappearance of the tendon reflexes of one leg. The prognosis was often excellent when the division of the cord was only partial.

Peripheral Nerves.

Not infrequently the only sequel to a bullet wound of a peripheral nerve, such as the median, was a combination of sensory with vasomotor and secretory disturbances. In some wounds of the sciatic nerve only the sensory fibres had been cut, and in other cases only the motor. All the muscles supplied by an injured nerve were not invariably paralysed to an equal degree. Thus, the extensor communis digitorum was the muscle to suffer most when the radial nerve was injured, the flexors of the index finger when the median nerve was injured, and the deltoid when the plexus was injured. It had also been noticed that the nerve supply of muscles was subject to great variations. Thus the muscles of the ball of the thumb were found to be more often supplied by twigs from the ulnar nerve than had hitherto been realized. It was also found that the pronator teres was not invariably supplied by the median nerve. Many new observations were also made in connexion with traumatic neuritis, especially with reference to the dependence of pain on a variety of stimuli. Thus every sound, every sudden optical stimulus, or every psychic insult might be enough to provoke an attack of pain. Among the trophic disturbances closely studied for the first time was traumatic hypertrichosis. The experiences of the war had done much to discredit Charcot's teaching as to the psychogenetic origin of the symptoms to which the term traumatic hysteria had been given. To assume that non-organic paralyses and sensory disturbances were due to the imagination was erroneous; and though it could not be denied that psychic insults could produce serious non-organic changes in the central nervous system, yet it was a mistake to regard the symptoms as hysterical; they were due to mental strain. The war had shown that mechanical insults were largely responsible for non-organic nervous lesions, and that psychic and physical shock acted in the same manner on the central nervous system. In the case of shell explosions, these two factors were inextricably combined.

Traumatic Neurasthenia.

A common accompaniment to traumatic neurasthenia was a slight rise of temperature. Symptoms of hyperthyroidism were also frequently observed, and not a few

¹ *Berl. klin. Woch.*, November 24th, 1915.

patients suffered from tachycardia, hyperidrosis, and tremor, and presented Graefe's and Chvostek's signs. Many cases of akinesia amnestica and of reflex paralysis, which had been wrongly labelled as "local traumatic hysteria," were observed. The relatively low vitality of the right hemisphere of the brain was shown by the enormous excess of left-sided over right-sided symptoms. In attempting to distinguish genuine paralysis from psychogenic or simulated paralysis it had been customary to divert the patient's attention, and to place the limb in a position in which it could only be maintained by muscular action. When the limb did not collapse instantly the genuineness of the paralysis was discredited; this was quite wrong. It had been repeatedly found that, though the patient could not bring his limb into a certain position without help, he could keep it there. Thus, in a case of genuine radial palsy, the patient could not extend his hand, but when it had been passively extended he could keep it in that position. When he attempted active extension, the antagonistic muscles were thrown into action.

CASUALTIES IN THE MEDICAL SERVICES.

Died on Service.

BREVET COLONEL ARTHUR HENRY MOORHEAD, Bengal Medical Service, died at Kyrle, Batheaston, on March 1st, aged 43. He was born on July 20th, 1872, the third son of Brigade Surgeon G. A. Moorhead, R.A.M.C., and educated at Edinburgh University, where he took the M.B., C.M. in 1893. Entering the I.M.S. as surgeon-lieutenant on July 28th, 1894, he became surgeon-captain on July 28th, 1897, major on July 28th, 1906, and lieutenant-colonel on July 28th, 1914, and was promoted to brevet colonel for services in the present war on February 18th, 1915. He had served in three campaigns on the North-West frontier of India: Waziristan, 1894-95, medal and clasp; Chitral, 1895, in the relief of Chitral, medal with clasp; and in the Tochi Valley in 1897-98, clasp; also in the third China war of 1900, in the relief of Peking, medal with clasp. Since 1901 he had been medical officer of the 16th Indian Cavalry. He went to France with the second cavalry division of the Indian contingent, in command of a field ambulance, was mentioned in dispatches, promoted to brevet colonel, and made an assistant director of medical services. He was invalided home last December. In 1908 he represented the Indian Government at the Plague Conference in America, where he read a paper. His eldest brother, Lieutenant-Colonel G. O. Moorhead, is commanding officer of the Nyasaland contingent of the Union Expeditionary Force, East Africa.

Captain Harry John Rutherford Jones, R.A.M.C., died at 139, Oakwood Court, Kensington, on February 26th, aged 41. He was educated at the London Hospital, and took the M.R.C.S. and L.R.C.P.Lond. in 1892. After acting as house-surgeon to the Poplar Hospital for Accidents, he went into practice in Kensington. He took a temporary commission as lieutenant in the R.A.M.C. on August 15th, 1914, and was promoted to captain on completion of a year's service.

Captain William Howard Nicholls, R.A.M.C., died of an accidental gunshot wound in India on February 22nd, aged 24. He was the son of Howard Nicholls, of Bramber Lodge, West Worthing, was educated at Guy's, and took the M.R.C.S. and L.R.C.P.Lond. in 1914. He joined the Special Reserve of the R.A.M.C. as lieutenant on October 19th, 1914, and was promoted to captain after a year's service.

Lieutenant William Williamson Kerr Duncan, R.A.M.C., died at Willow Bank, Grantown-on-Spey, on February 29th, aged 37. He was the son of the late Rev. Henry Duncan, of Crichon. He took the Scottish triple qualification in 1914, and had only recently taken a temporary commission in the R.A.M.C.

Miss Christina Murdoch Wilson, Queen Alexandra's Imperial Military Nursing Service, Reserve, daughter of the late Thomas Wilson of Glasgow, died of pneumonia at No. 14 General Hospital, Wimereux, France, on March 1st.

Miss A. B. Corfield, Staff Nurse, Q.A.I.M.N.S. Reserve, is reported in the casualty list published on March 4th as having died in Egypt.

Wounded.

Captain H. Shield, R.A.M.C.(T.F.), France.
Captain C. E. C. Cole, Canadian A.M.C., France.
Lieutenant H. O. Gough, R.A.M.C. (temporary), France.
Assistant Surgeon E. J. Fisher, I.S.M.D., Mesopotamia.

LOST AT SEA.

The P. and O. ss. *Maloja*, 12,431 tons, Captain Irving, R.N.R., which left London for the East on Saturday, February 26th, was struck by a mine or torpedo off Dover on the morning of Sunday the 27th, and sank in half an hour with the loss of over 150 lives. She was the largest, but not the newest, of the P. and O. boats. Of 456 persons on board 155 appear to have been lost—namely, passengers, 72 saved, 49 lost, total 121; European staff, 92 saved, 20 lost, total 112; Lascar crew, 137 saved, 86 lost, total 223. The ship's surgeon, Dr. Edgar Kennington (Bart's), was among those saved. Two medical men were among the passengers, Dr. W. K. Miley and Assistant Surgeon W. J. S. Maine; both were lost.

Dr. William Kildare Miley was educated in the school of the Royal College of Surgeons in Ireland, Dublin, and took the diplomas of L.R.C.S.I. and L.R.C.P.I. in 1877, also taking the M.R.C.P.I. in 1880. He then joined the colonial emigration service, in which he had risen to be the senior medical officer, and was on his way to Calcutta to take medical charge of a shipload of emigrants for the colonies. He was a brother of Colonel Miley of the Indian army, resided at Monkstown, co. Dublin, and was 63 years of age.

Assistant Surgeon William John Samuel Maine, of the Indian Subordinate Medical Department (Bombay), was born on December 12th, 1864, attained warrant rank on September 14th, 1887, and became first class assistant surgeon on September 15th, 1906. He had recently been serving with the Indian troops in Europe, and received the Military Cross for his services on January 14th, 1916.

DEATHS AMONG SONS OF MEDICAL MEN.

Christie, Dugald R., Second Lieutenant Royal Field Artillery, son of Dr. Dugald Christie, C.M.G., Principal of the Moukden Medical College, Manchuria, killed in action in Mesopotamia, on February 24th, aged 19. He got his commission as second lieutenant in the R.F.A. on March 24th, 1915.

Jalland, Stephen, Lieutenant 6th East Yorks Regiment, now reported killed in action on August 9th, 1915, at Chocolate Hill, Gallipoli, was the youngest son of Mr. and Mrs. Jalland, of York. He was educated at Bilton Grange, Uppingham, and Lincoln College, Oxford, and graduated in honours in the Natural Science Schools, and eventually took the degree of M.A. Soon after war was declared he obtained a commission in the 6th East Yorks Regiment, having previously been in the Oxford O.T.C.

Ramsay, Derrick Winson, Lieutenant 10th Battalion Sherwood Foresters, eldest son of Dr. F. Winson Ramsay, of Jesmond Dene, Bournemouth, killed in France on February 14th. He was educated at Sherborne, and was studying engineering at Durham University College of Science, Newcastle, when the war began. He got a commission as second lieutenant on September 17th, 1914, and was promoted to lieutenant a year later.

Robinson, Arthur Limnel, Second Lieutenant Royal Engineers, eldest son of the late Surgeon-Major Mark Robinson, I.M.S., died in France on February 26th of wounds received on February 17th, aged 34. He was born at Mercara, Coorg, Southern India, on July 18th, 1881, educated at Dover College and the Royal School of Mines, and subsequently held appointments in Siberia, the Malay States, and Northern Nigeria. He was invalided from Africa in March, 1915, and on recovery got a commission in the Northamptonshire Regiment. After training at St. Albans and Colchester, he went to the front on November 1st, 1915, and was posted to the 173rd Tunnelling Company, R.E. He had only recently been home on leave.

Wood, Eric A. W., Second Lieutenant 9th Battalion Duke of Wellington's Regiment, eldest son of Dr. Arthur Wood, of Woodroyst, Southport, and of Halifax, killed in France on February 25th, aged 20. He was educated at Haileybury, and was about to go to Oxford when the war began. His commission was dated January 7th, 1915.

MEDICAL STUDENT.

Layman, Douglas Arthur Campbell, Second Lieutenant 17th Battalion Lancashire Fusiliers, elder son of Arthur Layman, of 4, Dulwich Wood Park, Upper Norwood, died of wounds in France on February 22nd, aged 22. He was a grandson of Dr. William Papineau, was educated at Dulwich College, where he was in the O.T.C., and then joined St. Thomas's Hospital. From October, 1914, he served as a dresser on the Indian hospital ship *Glengorm Castle* till August, 1915, and got his commission in September, 1915.

NOTES.

HONOURS.

SENIOR SUB-ASSISTANT-SURGEON T. N. SWAMI NADHA NAIDU, of the Indian Subordinate Medical Department, now serving at Rushmore, has been awarded the Distinguished Service Medal for conspicuous courage and gallantry in action in Mesopotamia. Previous to the war he was in submedical charge of the 86th Carnatic Infantry at St. Thomas's Mount, Madras.

The *London Gazette* of March 3rd announces that the King has been pleased to confer the Order of the Royal Red Cross, second class, upon the following ladies, for services under the Belgian Red Cross in Flanders, between August and November, 1914: Miss C. E. A. Thorpe, matron; the Hon. Angela Manners, sister (organiser of the "Manners Ambulance.")

MEDICAL OFFICERS WANTED.

21st South Midland Mounted Brigade.

Three medical officers are wanted to complete Brigade at present on East Coast. Applications to Major D. M. Spring, S.M.O., R.A.M.C. (T.), Head Quarters, Hempton, Fakenham, Norfolk.

Ireland.

It was reported at the annual meeting of the St. Patrick's Home for Supplying Trained Nurses to the Sick Poor in Dublin that, owing to the decreased poverty, due mainly to the separation allowances, the health of the poor had been good, and the number of cases nursed had decreased during the year 1915. The nurses, however, had visited 34,640 cases. Much good work was done in giving mothers instruction in the care and management of children.

A hospital ship arrived at Dublin on February 27th with 620 wounded and sick soldiers, of whom 290 were cot cases. The proportion of medical cases, such as acute rheumatism, pleurisy and pneumonia, and trench nephritis was large. Two ambulance trains, each conveying 150 men, were sent to Cork and Belfast respectively. The remainder were distributed among the Dublin hospitals. The St. John Ambulance Brigade furnished 160 men for the stretcher work at the North Wall Extension and at the hospitals; 56 motor owners lent, and in many cases drove their cars, while the Irish Automobile Club provided 20 ambulances, and traders 7 vans temporarily converted. The ambulances of the Dublin Corporation and the Pembroke Council were also at work, and the transfer of all the soldiers was accomplished in about three hours.

Reference was made recently to cases in which two boards of guardians had cancelled appointments made by them of locumtenents nominated by their medical officers when joining the Royal Army Medical Corps. One of these has now been adjusted—the guardians of Delvin, co. Westmeath, having agreed, after considering letters from the medical officer concerned and Dr. M. R. J. Hayes, secretary of the Irish Medical War Committee, to re-elect the locumtenent nominated by the absent doctor. In the other case the Local Government Board has addressed a letter to the guardians of the Lisnaskea Union, stating that it is not prepared without the concurrence of the absent doctor to entertain the proposal of the guardians under which an essential part of the arrangement made with the absent doctor, to whom the guardians had granted leave of absence for twelve months, would be upset by the displacement of the locumtenent nominated by him. The consideration of the communication from the Local Government Board was postponed for a larger meeting of the guardians.

INDUSTRIAL TRAINING OF WOUNDED SOLDIERS.

The large dépôt for wounded soldiers from various Irish regiments at Tipperary is affording instruction to men discharged from hospital. About 1,500 have already been admitted, and 2,000 more will be sent there in time. All men who are fit undergo a course of physical exercise and military training, and it is hoped that a good proportion of them will shortly be ready to return to full or partial duty. Manual instruction classes in boot repairing, French polishing, motor driving and repairing, in stationary oil and gas engines used for farm or other work, and shorthand and typewriting have already been established. It

is also proposed to give classes in the management and fixing of telephones, painting, ironwork, etc. Gymnastic exercises, massage, radiant heat baths, and Swedish drill greatly assist in accelerating recovery. Members of the Almeric Paget Massage Corps are on duty under the direction of the medical officer in charge. All this work is the result of purely voluntary effort. The army authorities lent it their approval and take an interest in its success, but it is entirely financed by voluntary subscriptions and managed by a lay committee, of which the Commandant Colonel Gordon, C.I.E., and medical officer in charge Lieutenant-Colonel Sims Woodhead, R.A.M.C., are *ex officio* members.

THE RESEARCH DEFENCE SOCIETY.

The Dublin branch of the Research Defence Society, which has been in existence for seven years, held its annual meeting last week at the house of the Royal Dublin Society. The report stated that the subscriptions by the branch had decreased, partly by reason of the war, with its many claims, but for the most part because members and the public considered that the battle for truth was already won. But although members could congratulate themselves on a great victory, the fruits of which were seen in the many thousands of soldiers saved from death by the results of medical research, no victory was eternally won unless it was eternally fought for. It was suggested that all members should subscribe for the quarterly report, which contained information as to the general affairs of the society and its many branches and as to current medical research. The branch had made a contribution to the parent society and had a small balance in hand. Sir Frederick W. Moore, who presided, said that the society had been assailed by all sorts of calumnies, and in particular it had been alleged that its one object was the torture of animals. There was not in the society a single member who would countenance the infliction of the slightest unnecessary suffering on any animal, or any experiment not likely to help to alleviate the suffering man was heir to.

Dr. A. D. Waller, F.R.S., Director of the Physiological Laboratory of the University of London, then delivered an address on fat consumption during war. He pointed out that a dominant factor in the German economic situation was the amount of fat available for food and for explosives. A hundred tons of fat yielded about ten tons of glycerine, which could be nitrated to yield twenty tons of nitroglycerine. Germany has hitherto consumed fat at the rate of 106 grams per head—that is, in round numbers, 2½ million tons per annum. For industrial purposes Germany has used half a million tons, of which 100,000 tons went to nitroglycerine. Half has been grown at home, half has been imported. During the first year of the war Germany had required for food at least half her previous allowance—that was to say, at least one and a quarter million tons of fat, and, say, 350,000 tons for war explosives; she had not been able to produce this amount at home. She had imported it partly from or through neutral countries, and partly from occupied territory. Germany had taken fat from the food account for the explosives account, and was therefore starving her women. There was no excuse, he said, for allowing fat, oils and substances which went to the formation of nitroglycerine to enter Germany.

Scotland.

At a meeting of the curators of the University of Edinburgh on March 3rd a resolution of sympathy with the members of the family of Sir William Turner was adopted. After a discussion it was decided to adjourn the question of the appointment to the vacant principalship for a few weeks.

The directors of the Royal Blind Asylum and School, Edinburgh, have secured Newington House in Blakely Avenue, with several acres of ground, for the purpose of carrying out the institution's scheme for sailors and soldiers blinded in the war. The Scottish Education Department have agreed to recognize the institution as a centre for the training of blind junior students.

CRIPPLED AND MAIMED SOLDIERS AND SAILORS.

A conference of representatives of municipal and other bodies interested in working the Naval and Military

Pensions Act, 1915, was held in the City Chambers, Glasgow, on February 28th, to consider the model scheme drawn up by the Statutory Committee established under the Act for the constitution of the local committees. A meeting has also been held in Edinburgh. Meanwhile a scheme for the establishment in the West of Scotland of a hospital for limbless sailors and soldiers is making progress. At present the only hospital of the kind is Queen Mary's Auxiliary Hospital at Roehampton. A deputation, headed by the Lord Provost of Glasgow and Sir William Macewen, had interviews on March 3rd with the Director-General of the Army Medical Service at the War Office, and at the Admiralty with the Committee of the Roehampton Hospital, with Major-General Sir Francis Lloyd in the chair. Sir Alfred Keogh gave the deputation the assurance that the hospital proposed to be established in Scotland would enjoy the same privileges with regard to grants, etc., and receive the same recognition from the military authorities as the hospital at Roehampton, and added that there was all the more need for the establishment of a hospital in the West of Scotland in that the accommodation at Roehampton was overtaxed; something like 1,600 were awaiting admission. Similar assurances were received at the meeting at the Admiralty. The deputation afterwards visited the hospital at Roehampton. It is stated that the Provisional Committee, of which the Lord Provost of Glasgow is chairman, will now take practical steps to carry out the scheme.

England and Wales.

At the annual meeting of the Ancoats Hospital, Manchester, on February 27th, the chairman, Sir F. Cawley, M.P., said that, in common with other institutions, its expenditure had increased. A larger income was necessary, but it was a remarkable fact that the annual subscriptions were only about £12 less than previously, showing that the public recognized the great value of the hospital. As all the members of the honorary staff had accepted commissions in the army and six out of nine Sisters had taken up military duties, the work of the hospital had been carried out under great difficulties. The number of in-patients had been 1,816, out-patients 7,026, home patients 445, and accident cases 18,156. Up to the end of December last 165 wounded and sick soldiers had been admitted to the hospital and 325 received at the convalescent home at Warford, where there were 37 beds. At the end of the meeting those present had the opportunity of inspecting the wards and the extensions, which include new out-patient consulting-rooms.

THE MANCHESTER CHILD WELFARE SCHEME.

The Manchester City Council has taken an important step in the direction of extending the municipal scheme for child welfare. Owing to the war the Slade Lane Babies' Hospital, which belongs to the committee of the Manchester School for Mothers, has suffered financially to a serious extent, and there was some danger that it might be closed if it had to depend altogether on voluntary effort. The committee therefore offered to the corporation 18 beds in its hospital for babies, and while the Sanitary Committee would have accepted the offer, opposition came from the Finance Committee, which resolved to recommend the Council not to accept it. It appears that the proposal involved that the corporation should be responsible for one-half of the cost of upkeep of the beds; and though under the child welfare scheme the Local Government Board would in all probability have provided half, the cost to the corporation would be at least £350 a year. When the question came before the Council the chairman of the Sanitary Committee pointed out that the objection of the Finance Committee was really that there was already sufficient provision for these cases made by other Manchester hospitals, and, though he partly admitted this, the provision was rather for cases requiring only short periods of treatment, the average stay in the other hospitals being only about three weeks, whereas many of the children under consideration required upwards of twelve months' treatment in order that cure might be effected. Sir Charles Behrens said that at the Manchester Infirmary there were now 580 persons awaiting admission, and there were no cots

available for babies. Several members of the Council opposed the proposal, which was represented as being a beginning of the municipalization of the hospitals, and it was argued that other hospitals had an equal or even better claim to rate aid. The Council, however, accepted the offer of the School for Mothers by a large majority. The medical side of the school has already been taken over by the corporation.

Correspondence.

THE EFFECT OF POSITION IN AUSCULTATION OF THE HEART.

SIR,—I was very glad to read Lieutenant-Colonel Rudolf's letter in the JOURNAL of March 4th, pp. 361-2. His results are the same as those to which I have drawn attention in teaching now for some years; and in the same issue of the JOURNAL, on p. 359, in a brief record of the transactions of the Ulster Medical Society, mention is made of a short paper I read on this subject. The phenomena, however, are frequently observed; a patient with some infection—too much alcohol and tobacco are sufficient—develops both apical and basic murmurs; the patient is put to bed and the cause removed, and in time, short or long, days or weeks, the murmurs disappear. The explanation is obvious. But also the following is found: A man is examined for life assurance, and no murmur, or one very faint, scarcely detectable, is found; he is put on his back, and a distinct systolic murmur promptly appears, generally in the fourth space, but sometimes at apex or at base. The explanation here is not so easy. I saw a certificate in regard to an officer home from India from the late Sir William Broadbent, in which it was stated as his opinion that the murmur was not organic but functional, and that probably the phenomenon was due to want of muscle tone, so that the heart in the supine position slightly flattened itself against the vertebral column in the supine position, like an india-rubber ball that had lost its elasticity. For my own practice and guidance I have looked upon its presence as indicating want of tone, and not sufficient to reject a life under average circumstances or to debar from the services, but as an indication for stopping sudden sharp strains of the heart, as in that involved by a sedentary clerk joining the colours without some preliminary training and observation. Colonel Rudolf's advice to examine the patient in both positions and after exercise is sound.—I am, etc.,

Belfast, March 4th.

WILLIAM CALWELL, M.D.

THE SOLDIER'S HEART AND THE STRAINED HEART.

SIR,—I see that Dr. J. S. Manson (January 29th, p. 184) ascribes some of the cases of irritable heart to tobacco smoking. A piece of experience which came my way supports his view.

On the hospital ship *Asturias* were always a number of invalid hearts variously described as irritable valvular disease of the heart and deranged action, all of them having their fingers stained a deep mahogany brown from cigarette smoking. Colonel Hardy, R.A.M.C., examined and tabulated these cases, and wrote a report on them which was sent to the Director-General at G.H.Q., and was thought to be of sufficient importance to call for a report from his office, which amounted to a warning against the excessive use of cigarettes then prevailing in the army.

This question of cigarette smoking will probably be seriously considered one of these days because of the number of men who will be invalidated with tobacco hearts, called possibly by other names, all of whom will claim pensions as having been injured by war service. There is, I believe, no place where an attempt is being made to-day to separate the truly irritable heart from the heart which is merely irritable for the time being.

I have also a piece of evidence in favour of Sir James Goodhart's view that the irritable heart is, at any rate in many cases, our old friend the overdone heart masquerading under another name. During the past eighteen years it has been my custom at Cambridge to ask every patient whether and when he had had any trouble with

his heart, and who was his doctor. The evidence thus obtained showed that a large percentage of these irritable ineffective hearts dated back to the fourteenth to sixteenth year, when as boys at school they were in an athletic team struggling for pre-eminence—a struggle which the patient still looks on as being one of the toughest jobs he had ever had a hand in. The history, with the doctor's description, showed that the onset was gradual, although the realization of it by the patient was sudden. The irritable heart of the young man was the hypertrophied overdone heart of the boy.

We have still to find out whether the irritable hearts are all included in the classes roughly sketched in this letter, or whether the irritable heart of the soldier on active service is starting in him although he is nearer to his full development than these patients usually are. Then we shall have to find out what the truly irritable heart is.—I am, etc.,

ROBERT MICHELL,
Captain (temporary) R.A.M.C.

March 8th.

FERGUS(S)ON'S SPECULUM.

SIR,—Although the four men to whom this instrument has been ascribed were all contemporaries of many doctors still living, several correspondents who have read "Gynaecologist's" query in the *JOURNAL* of January 8th admit that the question remains unsettled.

"Fergus(s)on's vaginal speculum" means a tubular glass instrument, silvered and coated with rubber. The four men for whom it has been claimed are: (1) Dr. Robert Ferguson (1799–1865), Physician-Accoucheur to Queen Victoria, and the first professor of obstetric medicine and diseases of women and children to King's College. Several living contemporaries are under the impression that he was the inventor, but he makes no mention of the instrument in his *Essays on the Most Important Diseases of Women*, nor in his edition of Gooch's works. (2) Ferguson, a dealer whose shop close to the entrance to St. Bartholomew's Hospital was well known in the middle of the last century. His claim, as will be shown, is strong. (3) Sir William Fergusson, Bt. (1808–1877), who makes no mention of the speculum in his *System of Practical Surgery*, nor, I understand, in any of his other writings. He received his baronetcy in January, 1866—a point of some importance in this controversy. (4) Dr. W. E. Laing Fergusson, M.R.C.S. Eng. 1846, M.D. Glasg. 1854, who died in 1880.¹ I understood from Dr. Greenhalgh, under whom I studied in 1869–70 at St. Bartholomew's Hospital, that this Dr. Fergusson, who had just settled in Claremont Square, originally suggested this instrument.

The evidence from contemporary textbooks is conflicting. In the first edition (1835) of Churchill's *Diseases of Women* the instrument is not mentioned, but in the third edition (1850) it is described in a paragraph beginning "Dr. Fergusson (*sic*) has greatly improved . . ." whilst in the fourth (1857) the same paragraph reads: "Mr. Ferguson has greatly improved . . ." We may conclude that the spelling was corrected in the later edition. No Dr. Fergusson was known to obstetricians in 1850, and in 1857 the future baronet was Mr. Fergusson. In Mitchell's *Practical Remarks on the Use of the Speculum* (Dublin, 1849) and in Robert Lee's *Treatise on the Employment of the Speculum* (1858) there is no mention of a Ferguson's speculum, but Mitchell mentions a plain glass conical speculum covered with caoutchouc.

The evidence of makers, dealers, and catalogues must be taken into account. Messrs. Maw, Son and Sons have kindly informed me that they have listed "Fergusson's speculum" in their catalogues since 1851, and were always under the impression that Sir William was its inventor, but add that "we note that in an 1851 catalogue we spell the name with only one s." Mr. Barry Hopkins of Messrs. Arnold and Sons, a veteran in the trade, states that Dr. Ferguson of King's College was believed by many dealers to be the inventor, but, like Messrs. Maw, he notes that all concerned with the speculum when it was new—glass-blowers, silverers, and india-rubber workers included—have passed away and left no record.

I find, however, evidence of real weight in the *Catalogue of Obstetrical and other Instruments exhibited at the Conversazione of the Obstetrical Society of London, held by*

Permission at the Royal College of Physicians, March 28th, 1866, a valuable descriptive work on which is founded the catalogue of the loan collection of obstetrical and gynaecological instruments in the Museum of the College of Surgeons. At page 200 the speculum is thus described:

Ferguson's glass speculum coated over with a thin layer of india-rubber. This instrument is a very useful one, possessing great reflecting power, and capable of always being kept perfectly clean and bright for ordinary use; Dr. Churchill has found this speculum (of different sizes) the most useful.

This catalogue was published early in 1867, the editor dating his preface December, 1866. Sir W. Fergusson received his baronetcy in January, 1866, and the conversazione was held in the following March. In the notes on specula in the *Catalogue* "Dr." is placed before the names of all well-known medical inventors, Dr. Henry Bennet's, Dr. Marion Sims's, Dr. Tanner's, and other specula being fully described. Turning to dealers, I find at p. 202 "Hilliard's exhibited by Ferguson" (Hilliard being a Glasgow firm), "A speculum was exhibited by Durroch," then a dealer in St. Thomas's Street, S.E. It is true that it is stated that "Mr. Ferguson exhibited two vaginal retractors"—though the exhibitor must have been the dealer, not the baronet. Dr. Robert Ferguson had died in 1865, and was spoken of as "Dr." in Sir T. Watson's address at the Royal College of Physicians,² delivered three days before the conversazione. Sir W. Fergusson's newly acquired title could not have been overlooked, while Dr. Laing Fergusson had not come to London, indeed his name is not to be found in the *Medical Directory* for 1866, though he had qualified twenty years earlier, and it was not until 1870 that his address was given as Claremont Square, N. Thus the evidence of this descriptive catalogue must lead us to believe that Ferguson the dealer was the inventor. Perhaps, however, some reader of the *JOURNAL* may possess further evidence about the speculum and its inventor.—I am, etc.,

London, W., Feb. 2nd.

ALBAN DORAN.

VISUAL NEUROSES OF MINERS.

SIR,—Dr. C. F. Harford (*JOURNAL*, March 4th, p. 340) writes: "The name (miner's nystagmus) seems to be unfortunate."

I agree with him, but I doubt if it is going to help us to call it a "neurosis." In 200 consecutive cases of nystagmus collected in a coal-mining area only 12 per cent. were miners. If we call the 12 per cent. neuroses of miners, what are we to call the others when the manifestations in all the cases are practically identical?

In Dr. Harford's series of miners ametropia is the rule, but the same is true of non-miners. "Nystagmus occurring in a miner" is probably a better term than neuroses of miners.—I am, etc.,

Warrington, Mar. 7th.

J. A. WILSON.

TRENCH NEPHRITIS.

SIR,—Your annotation on this subject suggests that the theory of an infective origin for trench nephritis has only just been put forward. Claims for priority are seldom edifying, and it is with some reluctance that I venture to point out that this view was definitely advanced by me in the July issue of the *Journal of the Royal Army Medical Corps* (which was not published till September). I advocated the view as the result of work undertaken at the request of the Medical Research Committee, with the co-operation of Mr. Mackenzie Wallis and Mr. J. W. Trevan. I enclose a copy of my interim report, in which you will find practically all the points referred to in your annotation, such as the association of dyspnoea with the oedema, and the immunity of the Indian troops from the disease, as well as the extensive chemical and bacteriological investigations on which we based the infective theory.—I am, etc.,

London, W., March 4th.

W. LANGDON BROWN.

* * * The annotation mentioned by our correspondent begins with a reference to the discussion at the meeting of the Sections of Medicine, and Pharmacology and Therapeutics of the Royal Society of Medicine on February 19th. In opening that discussion Dr. Langdon Brown, as was reported at p. 273, indicated reasons for believing that the disorder was due to an infection.

Obituary.

R. D. MAXWELL, M.D., F.R.C.S.,

ASSISTANT OBSTETRIC PHYSICIAN, LONDON HOSPITAL.

WE regret to have to record the death, on March 6th, after an abdominal operation, of Dr. R. Drummond Maxwell. He was the son of Mr. Richard Maxwell, of Oxford Gardens, W., and received his professional education at the London Hospital; he graduated M.B.Lond. in 1897 and M.D. (in Gynaecology and Obstetrics) in 1904; he became F.R.C.S.Eng. in 1907. He took part in the Boer war as civil surgeon in the South African Field Force. He was for a time resident medical officer in Queen Charlotte's Lying-in Hospital, to which he was afterwards elected physician. Dr. Maxwell afterwards joined the staff of the Samaritan Hospital, where, as physician to out-patients, with some beds at his disposal, he distinguished himself greatly both for sound clinical knowledge and skilful operating. After a few years he was elected assistant obstetric physician and lecturer on midwifery to nurses at his old hospital. Dr. Maxwell communicated to medical societies and journals many excellent original memoirs, and when the late Dr. Herman was nearing the end of his career, that distinguished authority handed over his deservedly popular *Diseases of Women* to his younger colleague for the preparation of a new edition.

A Colleague at the London Hospital writes:

Of Maxwell's ability there is little need to speak; his academic distinctions, the position he had already attained in his profession, the success which had already come to him are surely sufficient testimony. Great though his professional attributes were, it is for other and still rarer gifts that those who knew him will continue to mourn for him and to dwell upon his memory. A wide and generous sympathy for all suffering, a detestation of cant and a passionate love of justice were mingled in his character with a natural geniality and a deep appreciation of the drama, poetry, and humour of life. The quiet courage with which during the last few years he had faced two serious abdominal operations was not lost on his friends. Maxwell, I believe, was never known to complain. Another striking feature was the interest he always evinced in military matters, a fact perhaps to be explained by his descent from a Scottish Border family. He had seen active service in the South African war, and for the last twelve months he was in command of the London Hospital Section of the University Officers' Training Corps. Nothing, however, compensated for the disappointment which he felt that owing to various substantial reasons he could not join our Expeditionary Force in France, for, like many of his countrymen, he had a strong sentimental regard for Scotland's ancient ally, and was strangely familiar with some of the more romantic chapters in her history. Such a man could not fail to be popular with both colleagues and students, and the widespread grief with which the news of his death was received bore remarkable testimony to the respect and affection in which he was held.

SAMUEL MACVIE, M.B., C.M.EDIN., J.P.,

CHIRNSIDE, BERWICKSHIRE

THE death, on March 2nd, of Dr. Samuel Macvie, at his residence of Herbertknowe, Chirnside, has removed a successful doctor and an outstanding and most interesting personality from the Border district of Scotland. He was in his 68th year. He was a native of Irvine, in Ayrshire. His circumstances in his early years in a coal mining district in the West of Scotland made it no easy task for him to enter the medical profession, and he used to tell with pardonable pride how he was set upon obtaining nothing less than a university degree and how he in consequence went back for a time to his work until he had made sufficient to carry him through the classes in Glasgow and Edinburgh. He graduated in Edinburgh (M.B., C.M.) in 1874, and for forty years (since 1876) he practised in Chirnside with a reputation extending far beyond Berwickshire. He was elected a Fellow of the Edinburgh Obstetrical Society in 1881 and of the Medico-Chirurgical Society in 1897. From time to time he exhibited specimens at the

meetings of the former society and took part, often with great acumen mixed with sly humour, in the discussions on obstetrical matters; and it was no surprise to those who knew him best when the fellows made him a vice-president in the years 1900-01. His paper entitled "*Mother versus child*," was an extremely clever and carefully worked out comparison and contrast between the value of the life of the mother and that of her unborn child, in which he came to the conclusion that, whilst the mother has realized the potentialities of life, the unborn infant has a potential value which is equal to its extra-uterine life-expectancy, and which may never be realized. Dr. Macvie felt that he had reached an *impasse* in his reasoning and smilingly was ready to admit that there was probably a fallacy somewhere. He had many original ideas upon many medical and especially obstetrical subjects, and his revolutionary notions on diet he put to the test in his own person, with no disastrous results but with apparent benefit, to the no small surprise of some who feared other consequences. He was greatly interested in art, and nothing pleased him better, on one of his rare visits to Edinburgh, than to spend half an hour or an hour in contemplation of a great religious painting. He was also delighted with his discovery of a local poetess in the person of the authoress of *Whinblossom*. He was medical officer for three parishes in Berwickshire and J.P. for the county. He was awarded the Volunteer Decoration as surgeon-major of the 1st Volunteer Battalion King's Own Scottish Borderers. He was for many years president of the Berwickshire Liberal Committee, and he also served as chairman of the Chirnside Parish Council and School Board. He had a fresh and original mind on all subjects of interest, and no man could place an apparently illogical statement before his hearers in a more convincing manner. His humour can only be described by the expressive Scots word "*pawky*." He will long be remembered in the Border Counties for his kindness of heart and his thorough grasp of medicine in all its parts. His wife predeceased him several years ago.

DR. ARCHIBALD THOMSON CAMPBELL, whose death on February 22nd was briefly noticed in the JOURNAL of last week, was an active and energetic member of the British Medical Association, having been chairman of the Division, president of the Branch, a representative at Representative Meetings, and a member of the Organization Committee. After graduating in 1886 he made one or two voyages to the East as ship surgeon. He settled in the north-western district of Glasgow, where he speedily built up an extensive practice. He took a great interest in the Insurance Act, and his constant endeavour was to make its working as satisfactory as possible from the medical point of view. He was unanimously elected chairman of the Glasgow Panel Committee, a position he filled with much acceptance to all concerned. He was attached to the Home Hospital Reserve, was mobilized at the beginning of August, 1914, and was appointed to the military hospital at the garrison, Maryhill, with the rank of captain, and carried on the arduous work required by both his civil and military duties till he was stricken down about five months ago by his last illness. Of a bright and happy disposition, with a marked sense of humour, he was very popular with the members of the profession in Glasgow and the West of Scotland, and to all who knew him his death has caused a feeling of irreparable loss. He was largely instrumental in forming the Glasgow Medical Golf Club. He leaves a widow and three children of school age, for whom the greatest sympathy is felt. He was buried with military honours at the Western Necropolis, Glasgow.

DR. EDWARD BERDOE, who died on March 2nd, was born in London on March 7th, 1836, and was therefore within a few days of the completion of his 80th year. He was educated at Regent's Park College, and began the study of medicine at a comparatively late period of life. After going through the curriculum at the London Hospital he was admitted L.R.C.P. Edin. and L.S.A. in 1876; in the following year he obtained the diploma of M.R.C.S. He worked as a general practitioner in Hackney for forty years. He was an ardent student of Browning, and was one of the founders of the society bearing the name of the poet: he was a member of its committee till its dissolution

in 1894. He was the author of *Browning's Message to His Time* (1890), *The Browning Cyclopaedia* (1891), *Biographical and Historical Notes to Browning's Complete Works* (1894), *Browning and the Christian Faith* (1896), and a *Browning Primer* (1904), and editor of *Browning Studies* (1895). Dr. Berdoe was a strenuous opponent of the germ theory of disease and of the experimental method in research, and he preached his doctrine with considerable ingenuity of argument. His outlook, however, was coloured by prejudice, as is shown by his books, *St. Bernard's: The Romance of a Medical Student*, and the key to it, *Dying Scientifically*, both published under the pseudonym of "Aesculapius Scalpel" in 1883. In the preface to *Dying Scientifically* he declared that he loved his old hospital, in which he had passed some of the happiest years of his life, and was grateful for all the advantages it had given him; the bitterness with which he denounced it and all other hospitals, and the medical profession as a body, may therefore be charitably attributed to the proverbial frankness of the candid friend. He displayed the same spirit in the *Zoophilist*, of which he was editor. He assisted Miss Frances Power Cobbe in the compilation of her notorious *Nine Circles*, and when the suppressions and misrepresentations of that work were exposed he had to bear his share of the responsibility for them. There is no reason to doubt his sincerity, but this makes it all the more lamentable that a man of his unquestionable ability and high character should have allowed himself to be so carried away by fanaticism. Dr. Berdoe was the author of a popular work on the history of medicine, entitled *The Origin and Growth of the Healing Art*, which, though made untrustworthy here and there by his dislike of experiment, is a readable introduction to the subject.

DR. FREDERICK WILLIAM WRIGHT, who died at Haddenham, Bucks, on January 31st, in his 78th year, received his medical education at the University of Edinburgh. After taking the diplomas of M.R.C.S. and L.S.A. in 1862 he joined his cousin, Mr. S. W. Fearn, surgeon to the Derby General Infirmary. In 1877, in conjunction with several medical friends, and with the support of Mr. M. T. Bass, M.P., Mr. H. H. Bemrose, then Mayor of Derby, and others, he founded the Derbyshire Children's Hospital, which has grown steadily to its present high state of efficiency. Dr. Wright was a generous benefactor to the building fund, and in September, 1915, his portrait was presented to the hospital board. He was also the originator of the Derby Nomadic Club, a debating society which has continued in active life since 1868. Dr. Wright gave up practice in Derby in 1889 and went to Colorado, where, although he did not engage in professional work, he received the honorary degree of M.D. from the University of Denver. After returning to England he practised for some years at S. Godstone, Surrey. When he finally retired from practice he occupied himself with research in London and Liverpool. His unselfish character made him beloved and trusted by all with whom he was brought in contact, and his professional skill and kindness of disposition made him very successful as a practitioner. Dr. Wright leaves one son, a surgeon in the Royal Navy.

DR. GEORGE VALENTINE, M.B., C.M.Glas., well known in Ayrshire as medical officer to the lighthouse-keepers on Ailsa Crag, died, aged 68, on February 15th in his home in Girvan, where he had been parochial medical officer for no less than forty-three years.

ALFRED BESWICK DARLING, M.B., Ch.B.Edin., D.P.H., died on February 20th in Edinburgh, where he had settled in practice after having held junior appointments in that city, and in Sheffield and Darlington. He graduated in 1906.

DR. GEORGE HENRY CHARLESWORTH, J.P., who died on February 8th, in Putney, aged 56, was the eldest son of Mr. Charlesworth of Syston, Leicestershire. He was educated at King's College and at Charing Cross Hospital. He was for many years district medical officer to the London County Council, and he was also honorary medical officer to the Actors' and Music Hall Artists' Associations. Dr. Charlesworth died deeply lamented by a large circle of friends, many of whom honoured his memory by attendance at his funeral at Syston on February 14th.

LIEUTENANT-COLONEL THOMAS HENRY WHITE, R.A.M.C. (ret.), died at Coolgardie, Caversham, on January 27th, aged 78. He took the degree of M.D. in the Royal University, Ireland, in 1858, and the diploma of L.R.C.S.I. in 1859, and entered the army as assistant surgeon on January 19th, 1860, becoming surgeon on January 19th, 1872, and surgeon-major on March 1st, 1875; he retired as brigade-surgeon on February 5th, 1890. The *Army List* assigns him no war service.

LIEUTENANT-COLONEL GEORGE FREDERICK WILLIAM BRAIDE, Bengal Medical Service, died suddenly at Lahore on January 6th. He was born on November 5th, 1862, educated at Owens College, Manchester, and in 1886 graduated M.B.Vict. Univ., and took the diploma of M.R.C.S. He entered the I.M.S. as surgeon on March 31st, 1887, became major on March 31st, 1899, and lieutenant-colonel on March 31st, 1907, and was placed on the selected list for promotion on August 25th, 1912. For the last nine years he had been Inspector-General of Prisons in the Punjab. The *Army List* assigns him no war service.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Isaac Ott, professor of physiology in the University of Pennsylvania, a former president of the American Neurological Society, and the author of several well-known textbooks on nerve diseases, aged 68; Dr. John O. Roe, of Rochester, New York, one of the leading laryngologists in the United States and a former president of the American Laryngological Association, aged 75; Dr. George P. Shears, clinical professor of obstetrics in the New York Polyclinic Medical School, aged 53; Dr. A. Alexander Smith, professor of the principles and practice of medicine and clinical medicine at the University and Bellevue Hospital Medical College, aged 69; Dr. W. P. Spratling, from 1894 to 1908 medical superintendent of the Craig Colony for Epileptics, Sonyea, New York, and later professor of physiology and nervous diseases in the College of Physicians and Surgeons, Baltimore, aged 52; Dr. Thuilié, formerly president of the Paris Municipal Council and vice-president of the Superior Council or the Assistance Publique, aged 84; and Dr. Vaillant, one of the members for Paris.

The Services.

EXCHANGE DESIRED.

CAPTAIN (November, 1914) in 2nd line Territorial Field Ambulance, at present stationed in Scotland, wishes to exchange with officer in Field Ambulance in France.—Address No. 1050, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

NATIONAL UNIVERSITY OF IRELAND.

Special Medical Examinations.

THE Senate of the National University of Ireland has directed that the special examination for medical degrees to be held in June next shall be open only to candidates who, if qualified as a result of that examination, undertake to apply at once for commissions in the Indian Medical Service, the Royal Army Medical Corps, or the Naval Medical Service.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMMITTEE was held on March 7th, Dr. Frederick Taylor, the President, being in the chair.

A letter was received from the Council of the Royal Society with reference to the establishment of a Conjoint Board of Scientific Societies for the purpose of promoting the co-operation of those interested in pure or applied science, and asking the College to nominate two representatives to meet the Council of the Royal Society at a conference to be called at an early date. The President was asked to nominate two Fellows to act as representatives.

The greater part of the time was occupied with the discussion of a subject which was declared to be "secreta Collegii."

APOTHECARIES' HALL OF IRELAND.

THE Court of Directors has adopted a resolution placing on record its regret at the death in action of Captain Seymour Sritch, an ex governor, as announced in the BRITISH MEDICAL JOURNAL of February 19th, p. 288, and expressing its sympathy with his widow and relatives.

Medical News.

At the meeting of the Royal Microscopical Society on Wednesday next, at 8 p.m., Professor J. Arthur Thomson will speak on original factors in evolution, and Sir E. Ray Lankester on the supposed exhibition of purpose and intelligence by the foraminifera.

At the meeting of the Medical Society of London on March 20th, at 8.30 p.m., a discussion on gunshot wounds of the spine will be introduced by Captain James Collier and Lieutenant-Colonel Donald Amour, F.R.C.S., who will deal respectively with the medical and surgical aspects of the subject.

THE Italian Government has decided to grant official recognition to the national factory of artificial limbs for men who have been maimed in the war, recently established at Milan with a capital of £8,000 collected by a committee for the purpose of supply orthopaedic apparatus at cost price.

It is announced that Harvard University proposes to establish a course of military medicine in its graduate medical school. It is to be under the charge of Major Weston P. Chamberlain of the United States Army.

At the annual meeting of the governors of Queen Charlotte's Hospital it was reported that since the outbreak of war over 1,600 wives of soldiers and sailors had been admitted to the wards of the hospital or attended and nursed in their own homes at a cost to the hospital of nearly £3,000.

THE Bureau of the American Census, in a report recently issued, states that the number of suicides recorded in the United States in 1914 was 10,933, or 16 per 100,000 of population. In 3,286 cases death was caused by shooting, in 3,000 by poisoning, in 1,552 by hanging or strangulation, in 1,419 by asphyxia, in 658 by the use of knives or other cutting or piercing instruments, in 619 by drowning, in 225 by jumping from high places, in 89 by crushing, and in 85 by other methods.

DR. W. W. KLEN, of Philadelphia, Emeritus Professor of Surgery in Jefferson Medical College, has been re-elected President of the American Philosophical Society for 1916.

THE supply of vehicles has run so short in Vienna that the work of medical men, particularly by night, has been greatly embarrassed. The Viennese doctors, with the help of the police, clubbed together and secured one motor car, to be kept ready all night at the disposal of the medical profession in a central garage. But even this modest provision appears to have proved very costly.

THE Cavendish Electrical Company (105, Great Portland Street, London, W.) has issued a pamphlet on the equipment of the electrical department of a military hospital or convalescent camp, a matter on which the company has had considerable experience. The pamphlet contains illustrated accounts of a large variety of apparatus.

ON March 1st a goodly company assembled at Dr. Williams's Library, University Hall, W.C., for the annual meeting of the Mental After-Care Association. After a few opening remarks from the Dean of Westminster (Bishop Ryle), who presided, the report for 1915 was read and proposed for adoption by Dr. Henry Kayner, the chairman of Council. It showed that in spite of the war the work of the association had been actively carried on; 379 cases had applied for assistance, which was afforded, to all found suitable, in the way of supplying temporary homes on leaving asylum care, grants of clothing and of tools, as well as attention to health, and finding situations for which they were fitted. The strongest evidence of the utility of the charity was, however, afforded by the prevention of relapses. The resignation, through ill health, of Mr. Thornhill Roxby, after twenty-eight years' strenuous and sympathetic work as secretary, was regretfully alluded to. Miss E. D. Vickers, who has had long experience as assistant and acting secretary, has been appointed in his place. The receipts from all sources during 1915 amounted to £1,370 6s. 8d., and, though subscriptions had only slightly fallen off during the war, there was need for fresh efforts to meet adequately the calls on the association. The trustees of the Queen Adelaide Fund had arranged to secure the co-operation of the association in investigating the conditions of patients discharged from the London County Council asylums in view of a grant from that fund, and this will eventually mean a largely increased scope of work. The adoption of the report was seconded by Dr. Percy Smith, supported by Mr. Goodrich, L.C.C., and carried, as was the financial statement.

Letters, Notes, and Answers.

THE telegraphic addresses of the British Medical Association and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atiology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

EPSOM COLLEGE.

ON October 16th, 1909, Dr. John Herbert Wells, of the Inoculation Department of St. Mary's Hospital, died after eighteen months of suffering from glanders contracted in the laboratory in the course of a research on the treatment of that disease. He was only 30 at the time of his death, and left a widow and two young children almost totally unprovided for. His son, John Clayworth Spencer Wells, aged 8, is a candidate for a foundation scholarship at Epsom College at the 1916 election. The case seems to us an exceptionally deserving one in view of the fact that the boy's father died a martyr to science. We may add that it is strongly supported by Lord Moulton, Lord Ribblesdale, Mr. Arthur Balfour, Sir Almoth Wright, and Sir W. Arbuthnot Lane.

TRENCH NEPHRITIS.

DR. J. C. MCWALTER (Dublin) writes: There is some reason to think, I submit, that epidemic nephritis or trench nephritis is a renal manifestation of a paratyphoid affection. None of the British experts seem to favor this view, but it has lately been advocated by observers in Vienna. What are the known facts? An inflammatory affection of the kidneys is suddenly found to attack a large number of previously healthy men under 40. They present two characteristics differentiating them from other men of the same class: they live in trenches, and they have all been inoculated against enteric fever. In former campaigns, as in Africa, men, mostly not inoculated, developed enteric under like conditions. Typhoid is comparatively rare in the present campaign, but there are various paratyphoid conditions prevalent. Osler states that there is a renal form of typhoid. I have found bacilluria present in epidemic nephritis long after the original attack.

MAGNESIUM SULPHATE LOTION IN CELLULITIS.

LIEUTENANT S. A. B. PAYMASTER, I.M.S., Cameroons Expeditionary Force, writes that from the beginning of the war he has used a lotion of supersaturated solution of magnesium sulphate (35 grains to an ounce of cold water) with remarkable results in lymphangitis, cellulitis, erysipelas (especially of cellulocutaneous type), orchitis, epididymitis, and all other vague oedemas and swellings. The lotion is applied frequently. The pain, tenderness, and swelling markedly decrease from the first day and disappear in a few days.

ANA OBSTETRICA FOR THE CURIOUS.

TIRESIAS writes: At a distant farm in the weald of Kent the other day I learnt that the father of my patient was one of a family of twenty-two children, most of whom survive. On the way home my chauffeur (a native of the part) told me of an old lady in the town near that used to say she had had twice two and twenty children, explaining the riddle by the remark that she had had twenty-two straight on; one died and then she had another, thus having twenty-two twice over. More than forty years ago, in a town in the West Riding, an old lady I met at a confinement also told me she had had twice two and twenty children. Her solution was different—twins twice and twenty after had been the order of the arrows in her quiverful, but she added that very few of them were at that time alive. At a maternity case the other day the mother assured me that she was one out of nineteen, fifteen of whom still survive.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	2 s. d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

A Clinical Lecture

ON

THE IMPORTANCE OF GENERAL PRINCIPLES IN MILITARY SURGERY.

DELIVERED AT THE ROYAL VICTORIA INFIRMARY,
NEWCASTLE-UPON-TYNE.

By G. GREY TURNER, MAJOR R.A.M.C.(T.F.),
FIRST NORTHERN GENERAL HOSPITAL.

I HAVE chosen this subject because many of you will before long enter the service of your country as military surgeons, and because the application of principles to practice is a most useful lesson for us all.

The military hospital with which I am associated is situated in a district in which there has always been a big garrison, and much of my work has been concerned with the ordinary surgical ailments arising among any large body of men, and some special troubles connected with the training of the soldier. The latter is a matter which will repay review, and with which I hope to deal at another time. To-day we are only concerned with the wounded returned from Flanders or the Dardanelles—the "overseas cases," as they have come to be known.

To many of us the work of this campaign has been our only experience of military surgery, and at first we were mainly impressed by its novelty. One was led to adopt this attitude by the fact that military surgery is commonly spoken of as apart from everyday surgery. Books are specially written on military surgery; colleges are set apart for its study, and in the old days at our own school there was a professor of military surgery. However, it was not long before I learnt that the principles which underlie surgical practice in general are exactly the same as those which govern the injuries met with as the result of modern firearms. In nearly all the reports from the seat of war the need of guidance by general principles is being recognized.

The peculiarities which undoubtedly exist are due to the nature of the weapons and to the conditions under which the wounds are received, and in which the injured man has to exist for some time afterwards. In other words, it is a question of environment rather than any inherent peculiarity in the wounds themselves.

The Treatment of Wounds in War.

It has been said that antiseptics in war surgery are of no value, and some have gone so far as to infer that antiseptics are therefore useless in general. Many things have been learnt and much excellent work has been done, but nothing that has upset the principles laid down by Lister with regard to the treatment of wounds. It is true that when the men reach the base or a hospital in England the greater proportion of the wounds are infected, but this is largely a question of environment. Owing to the ghastly nature of modern warfare the wounded may have to lie for many hours—men have spoken to me of lying for days—before they can receive any attention whatever, and the range of modern artillery is so great that the attention they then receive is only of the nature of first aid, for it is impossible at the dressing stations to do more; and it may be only after he has reached the clearing station, situated eight or ten miles behind the firing line, that his wounds can have anything like adequate attention. Even in these latter hospitals, after a big action, when large numbers of wounded pass through, it is only very few that can be dealt with as adequately as the principles of wound treatment demand.

Then again the wounds are often inflicted under filthy conditions, for the clothing may have been worn for many days or even weeks, and is nearly always soiled with earth which has been richly manured and highly cultivated for years, and which is found to be teeming with organisms. In these circumstances the possibilities of sepsis are infinite. Further, the nature of the wounds themselves renders proper antiseptic treatment difficult, for they are often irregular, with numerous pockets and side channels, and frequently contain foreign bodies which in their turn carry into the depths parts of the clothing or equipment. I know, as the result of the experience of men from our

own school, that when war wounds come under observation before the organisms have actually begun to multiply in the tissues, that is to say, within six or in some cases even twelve hours, then such wounds can be so treated with antiseptics that they do not become grossly infected, and heal much as wounds so treated would heal at home.*

The nature of many of the wounds, especially those produced by shells, makes them exceedingly difficult to cleanse even under the best possible circumstances, and to deal thoroughly with some such would be quite a major operation taking a considerable time. I am afraid that unless the body can be protected against sepsis by some means without local interference, then we must always be unwelcome witnesses to the septic infection of a certain proportion of wounds sustained in warfare. Lister always admitted that the antiseptic treatment of wounds was of more prophylactic than therapeutic value. What is now wanted is some plan to deal with infection when once started, and along these lines much useful work is being done.

Practically all the wounds that have reached us have been septic, and nothing has given me more satisfaction than the way they have healed when treated by the ordinary antiseptic plan as carried out in this hospital. For wounds already infected we largely rely on boracic fomentations, gauze wrung out of 1 in 1,000, mercury perchloride and used moist, or a solution of the same strength made with methylated spirit, and at times irrigation with solutions of hydrogen peroxide, or iodine water. One or two cases have been disappointing, but the great majority have done splendidly so far as wound healing is concerned. In the process of healing there are many stages, and the plan may have to be altered from time to time during the progress of the case, and other adjuncts to recovery must be employed.

Drainage.

All who have had to deal with the wounded are insistent on the importance of drainage, and when one considers the undermining of the tissues, the masses of broken-down material that must be cast off by a suppurative process, and the pockets and side channels which so frequently occur, it is easy to understand the necessity of providing a free outlet for discharges.

The method of drainage is important, and though tubes are undoubtedly the best means, there are abuses and dangers associated with them which we have learnt in the surgery of civil life to avoid. Tubes ought not to be too big. They should be removed the moment they have served their purpose, and it is especially important that they should not be placed in the neighbourhood of blood vessels, for in the presence of sepsis tubes are capable of producing erosion of the latter leading to very serious hæmorrhage.

Counter openings are very useful, and cannot always be superseded by the use of tubes.

Quite recently I had to deal with a case in which a subcutaneous laceration had been produced extending down the whole of the length of the outer part of the thigh. The torn muscles were infected and sloughing, and the patient was exceedingly ill. From a point near the trochanter a large tube, nearly a foot long, had been introduced throughout the whole length of the wound, but it was for the most part merely acting as a foreign body. The necessary requirements for the exit of discharges were met by making a series of counter openings through which much shorter tubes were introduced, and thus efficient drainage provided.

This is an extreme instance, but the necessity of providing counter openings should always be borne in mind. I would also draw attention to the importance of position as an aid to drainage, and I was especially impressed by this in the following cases:

A lad had been wounded through the leg and foot. The bullet entered about the middle of the inner aspect of the tibia and found an exit through the middle of the sole, "blowing out" quite a large focus from the bones which had been traversed. In consequence there was a large funnel-shaped wound, with the apex in the tibia and the base in the sole. The condition was grossly infected, and there was a copious discharge of pus. In spite of free drainage, frequent dressings, passive congestion, and the use of sedatives, he was constantly in severe pain as he lay with his foot propped up on a pillow.

* Since this was written, the value of antiseptics in "wounds in war" has been endorsed by Sir Anthony Bowlby in his recent Bradshaw Lecture (see BRITISH MEDICAL JOURNAL, December 25th, 1915).

At this stage the case was seen by my friend, the Rev. Robert Stirling (now a lieutenant in the Royal Army Medical Corps), whose experience of gunshot wounds sustained in the civil life of the Holy Land makes his advice especially valuable at the present time. He suggested that the pillow should be removed and the head end of the bed raised so that the discharge could constantly run out of the wound. The effect was very striking, for pain immediately ceased and recovery was greatly aided.

A similar condition occurred in the humerus in a case in which the wound of exit lay over the head of that bone. This man kept developing secondary abscesses halfway down the arm in spite of a tube introduced right into the medullary cavity. When the foot of the bed was kept raised so that gravity aided the escape of pus, this trouble was got over and recovery was much hastened. In this case a counter-opening about the middle of the arm might have served the same purpose had not the simpler plan succeeded.

Another principle which we have relearnt during the last few years is the importance of fresh air in combating infections. This was well known to our forefathers, and in his delightful account of Alanson of Liverpool my friend, R. W. Murray, shows how that surgeon insisted upon it one hundred and thirty-six years ago. Though employed principally in connexion with tubercle, its usefulness is not limited to the ravages of any particular organism. My septic cases have improved enormously when kept on the balcony or in open tents both day and night, and I believe that no single factor has been of more benefit to patients poisoned with sepsis than the free use of the open air. An illustrative story will suggest to you what happens in these circumstances. Two practitioner friends met in the street. In response to an inquiry Dr. P. said he was sorry to confess that he had a case of puerperal sepsis. Dr. M. inquired how the case was getting on, and was interested to hear that it was progressing favourably towards recovery. Curiosity being stimulated, Dr. M. next asked how the patient was being treated, and was informed that she was having antistreptococcic serum. He remarked on the great expense of the treatment, to which Dr. P. replied that it was costing nothing, for the patient was manufacturing the serum herself!

There is a wealth of meaning in this story, for there can be no doubt that if by fresh air, good food, etc., you can help the patients to make their own antitoxins, they will do it more surely and much more safely than you can possibly do it for them. But it must not be thought that I do not believe in the use of artificially prepared antitoxins, etc. I have to regret three instances of death from septicaemia in both its acute and chronic forms, which I cannot help feeling might have been cured by some form of antitoxin or vaccine had we been sufficiently informed to know exactly what strain was required. Antitoxins and vaccines for the cure of surgical sepsis undoubtedly occupy an important place, but at present it is far behind the other measures which we can employ.

Fig. 1 shows some large sequestra I removed recently from the ilium. The patient was a soldier, aged 39, who was wounded

FIG. 1.—Separated and necrose¹ fragments from a case of gunshot wound of the pelvis.

generally felt ill and miserable. There was a large sinus over the centre of the ilium, in the position of the exit wound, from which flowed a copious discharge of offensive pus, and at the bottom bare bone could be felt. Here, then, was a man presenting all the signs of a chronic intoxication from

sepsis. He had been carefully treated in hospitals in France and at home, but absorption still continued. With careful dressing and feeding he certainly improved a little, but not much; at the end of a fortnight he was much as before, and with a not very hopeful outlook on life. As about six months had elapsed since the infliction of the injury I judged that there would be good formation of new bone, and that the sequestra might safely be removed. The fragments shown were extracted under anaesthesia and the cavity left, which was almost big enough to hold the fist, was packed with gauze soaked in turpentine. The improvement was immediate and remarkable, for his whole temperament appeared to change, and he became bright and cheerful, and has made a splendid recovery.

I quote this case to show the importance of removing a septic focus. It is a principle in surgery which is apt to be forgotten that all the gross sources of sepsis ought first to be dealt with before falling back on vaccines, etc. It is largely a question of proportion or perspective, and the great thing is to remember first to remove the cause as far as possible, and then to adopt the other measures in the order in which they may be expected to do the most good.

When we come to the question of serum-therapy in prophylaxis we are on very hopeful ground. Last session I spoke on this matter in connexion with the prevention of tetanus,¹ and now I am glad to say that for many months past we have scarcely had a single case, due to the fact that the wounded men are all getting a prophylactic dose of antitetanic serum. The importance of this measure was very well illustrated by the experience of my colleague, Captain Heslop. In one batch of 32 wounded admitted to his wards only one man had not had a dose of antitetanic serum, and he developed acute tetanus on the twelfth day. It proved fatal in thirty-six hours.

Latent Sepsis and the Recrudescence of Sepsis in Healed Wounds.

That septic organisms often lie dormant in war wounds has frequently been illustrated, and has been remarked by most surgeons. One often sees cases of gunshot wounds in which the patient goes on perfectly well for two or three weeks, and then without any demonstrable cause there is an outburst of sepsis. It may take the form of local inflammation only, but there is often cellulitis, lymphangitis, and grave constitutional disturbance due to absorption (sæpæmia), or to the presence of the actual organisms in the circulating blood (septicaemia). The condition is not always a relapse, for the manifestation may be much worse than any primary septic trouble, and it is not necessarily due to the introduction of fresh infection because it can occur with healed wounds and without any breach of the surface. I have frequently noticed it after the amputation of fingers shattered by gun fire, and it may occur as the result of massage or the movement of previously infected joints. Sometimes tetanus has been lighted up in this way, though I have not myself seen it. As bearing on this problem, it is well to remember that the organisms of tetanus and gas gangrene have been found in gunshot wounds without either of these diseases resulting. It is, then, reasonable to suppose that they may get locked up in the tissues only to give rise to their specific infections when conditions for their development are more favourable. That organisms or their spores may survive for long periods is proved by the case of a Belgian who was under my care in October, 1914, with multiple shrapnel wounds of the arm. Six weeks after the casualty he developed symptoms suggestive of tetanus, but they were very mild, and I always doubted the diagnosis. Exactly twelve months afterwards he developed typical tetanus and passed through a long illness with dangerous exacerbations. The most serious instance I have come across is the following:

A corporal was admitted to the military hospital on July 30th with numerous small wounds on both legs, the result of a bursting shell. The wounds were not looked upon as serious, and there was only a little irregular pyrexia, the temperature never rising above 100° F., nor was the pulse ever above 80. The wounds soon became healthy granulating sores, and the patient was getting on so satisfactorily that he was up and walking about. On August 27th he went out without his great-coat, staying out of doors for a considerable time. He felt cold and poorly at night, and next day had a rigor. The right leg became swollen and painful, presenting the signs of severe cellulitis with lymphangitis and enlarged groin glands. Symptoms of severe general infection rapidly developed, with a temperature of 103° F., rising to 104°, and on the day of his death—a week after the onset—reaching 106°. Post-mortem examination showed evidences of death from general septicaemia without any other cause than the wounds on the legs.

These conditions are certainly very striking, though not peculiar to war surgery, and there must be some general principle involved. Many years ago, when on a voyage from the Gulf of Bothnia, I sustained a scratch over the right elbow in the course of my efforts to help the crew to right a cargo of iron ore in anticipation of the severe weather which followed. I thought nothing of it at the time, but, on arrival at home about a week later, developed severe cellulitis; it was very painful, made me feel quite ill, and had to be incised. In the course of two or three weeks everything seemed all right again, and I had no further trouble until exactly twelve months later, when, without any reason which I could assign, the cellulitis recurred, and was sufficiently bad to require a further incision just by the side of the old one. The following is a brief note of a case occurring in a soldier, which illustrates the same thing:

A man was wounded on April 25th, 1915, a small fragment of shrapnel lodging in the neighbourhood of the knuckle of the ring finger of the left hand. It was only a very slight wound, and, after removal of the fragment, it healed in three days. He thought nothing of it, although occasionally the place ached a little.

Some time after this a high-explosive shell burst close to him, and he was invalided home with shell concussion. August and September were spent in the country, and on September 25th, when in splendid general health, the injured finger suddenly swelled up and became very painful, while the pain went up his arm and the glands in the axilla became enlarged. There was a little local infection, a small abscess bursting and discharging. There was no sign of any foreign body. After a few days the whole thing cleared up, and he was all right again.

The Reopening of Healed Wounds.

Another trouble which is sometimes spoken of as if peculiar to war wounds is the breaking down of a scar apparently completely consolidated, but in these cases there is often a definite and tangible cause.

A soldier was wounded on May 16th as the result of the bursting of a hand grenade. He sustained a shattered fracture of the lower end of the ulna, and some portions of shrapnel were removed. On May 25th he was admitted to the 1st Northern General Hospital with a healthy granulating wound which was apparently soundly healed at the end of a month. He was sent to a convalescent home, but he had not been there long before the wound broke down and discharged. It again healed and was apparently all right when the same trouble recurred and delayed his return to duty. At the end of eight weeks the wound was apparently perfectly sound, and after inspection by an experienced surgeon he was marked for sick furlough and return to duty, but on the day on which he was to leave the home the wound again commenced to discharge, and he was readmitted to the 1st Northern General Hospital. An x-ray photograph showed there was still some necrosis, and under an anaesthetic I found a small cavity which contained the sequestra shown in Fig. 2. After their removal the wound healed from the bottom and gave us no further concern.

Another similar case was due to a metallic foreign body:

A young private was wounded in May by the bursting of a hand grenade. The right knee, left leg, and left foot were each injured, and in France portions of casing were removed from all the wounds. They all healed soundly except that on the foot, which healed and broke down many times. After being in hospital four months, he was discharged with the wound healed, but ten days later it again reopened, and he was admitted to the 1st Northern General Hospital. He then presented a scar on the outer part of the dorsum of the left foot, with a small unhealed area at one end. No foreign body could be felt, but x-ray examination showed a metallic fragment imbedded in the os calcis. At the operation for its removal the foreign body was found imbedded in granulation tissue which was directly connected with the under surface of the scar.

Sinuses.

It is an established principle that a sinus is to be looked upon as a symptom and not a disease, and before any consideration of treatment it is necessary to diagnose its cause. It is common to see men wounded at the war who for some considerable time afterwards, when in perfect

general health, present a sinus, discharging more or less pus, and a local rather than a general inconvenience.

Sometimes a gross foreign body, such as a portion of projectile, is still *in situ*, but these are the simple cases not likely to be missed.

An example is that of a man who was wounded at the battle of the Aisne on September 13th, 1914. The bullet entered the upper part of the right thigh just above the trochanter. He was treated at various hospitals, and was finally given sick furlough for a month. During all this time the wound never completely healed, and on December 9th he was admitted to the 1st Northern General Hospital with a small sinus just above the trochanter on the right side. The x-ray photograph demonstrated a shrapnel bullet, and under an anaesthetic this could be easily felt, and was removed together with a portion of garment. The sinus promptly healed, and the patient was soon able to be discharged cured.

I have recently had the following case under my care:

A man of 22 was wounded in the right thigh by the bursting of a bomb on July 16th, 1915. A piece of casing was removed from the back of the thigh by a separate incision on July 24th. The wound made for the latter purpose healed almost at once, but the original wound continued to discharge, and he was admitted to the 1st Northern General Hospital on July 30th. The original wound was quite small, and was represented by a sinus which passed right across the thigh to the inner side. Nothing could be felt with the probe, and x-ray examination was entirely negative. The patient himself was perfectly well, but every now and then there was a considerable discharge of pus from his wound, which never completely healed. Rest with irrigations and suitable dressings certainly caused a diminution of the discharge but did nothing to obliterate the track, and on September 18th, under an anaesthetic, I explored, and after enlarging the external aperture removed a piece of clothing about an inch square, evidently a portion of the man's trouser. After this the sinus rapidly closed, and he had no further trouble.

Another frequent cause is the formation of a sequestrum; the number of sinuses due to this is very remarkable. In military surgery a very considerable injury to the deeper tissues may result with a very small wound of the superficial parts. Fig. 3 is drawn from an x-ray photograph of the femur, and Fig. 4 shows the sequestra subsequently removed, in the case of a man whose thigh was traversed by a bullet from front to back. The

FIG. 3.—Showing comminution and necrosis of the femur, the result of a bullet wound.

FIG. 4.—Sequestra removed from the same case as the preceding figure.

casualty happened on May 15th, and he came under my care on June 20th with a sinus leading down to the femur. On September 26th the sequestra (Fig. 4) were removed, after which the sinus began to heal.

Secondary Haemorrhage.

In connexion with this subject well-established surgical principles are constantly being exemplified, and it is interesting to know that these principles were first formulated as the result of the experiences of a great military surgeon—George James Guthrie—who gained his knowledge in the Peninsular wars, chiefly between 1808 and 1815, when he operated on many of the wounded from Waterloo. His *Commentaries on Surgery* will well repay

study at the present time. Guthrie showed conclusively that in cases of secondary haemorrhage the bleeding very often came from the distal end of the injured artery, and that it is therefore necessary to expose the artery at the site of the wound, and to tie both ends rather than adopt the plan of the proximal ligature which was the favourite method up to his time.

A very striking illustration of this principle was furnished by the following case:

A man was wounded by a bursting shell which ploughed up the tissues over Scarpa's triangle. The femoral had to be tied just below Poupart's ligament, and the patient was admitted under my care some days afterwards with gangrene of the leg and a deplorably septic wound all over the front of the thigh. I had scarcely left the hospital after seeing the case when I was hurried back on account of alarming haemorrhage. The patient was exceedingly ill, and had lost so much blood that I thought the ligature applied to the cut end of the femoral artery must have given way. As a matter of fact the bleeding was from the end of the profunda femoris, which was lying exposed in the wound, the parent trunk having sloughed away. This, then, was an excellent instance of secondary haemorrhage from the distal end, or rather a distal branch of a severed artery. Had the ordinary principles been neglected, and the external iliac artery ligatured, the haemorrhage would probably not have been arrested, or would have recurred owing to the freedom of the collateral circulation. Though the patient was exceedingly ill he rallied sufficiently to allow me to amputate the thigh a day or two later, and ultimately made a complete recovery.

On the Removal of Foreign Bodies and the Use of the Roentgen Rays.

You cannot see much of military surgery without being confronted with the problems connected with the removal of foreign bodies, nor will you be long without appreciating the enormous value of the *x* rays. Let me state very clearly the conclusions at which I have arrived as to the removal of foreign bodies from patients arriving at a base hospital at home.

I think that in the great majority of cases it is a wise thing to remove a foreign body if this can be done without running any grave risk so far as the life of the patient or the function of the affected part are concerned. We are constantly getting patients admitted to hospital whose wounds are healed and who have returned to duty, but who do not feel happy in their minds because of the knowledge of the presence of some extraneous foreign body in their anatomy. I find that it makes all the difference in the world to a man whether his foreign body is in his chest wall or his waistcoat pocket. It is, after all, a psychological matter in many cases, and if such a gross mechanical performance as a surgical operation can lift a permanent load from the patient's mind, then strong reasons are required before you should desist from your efforts. Certain principles must always be kept in mind. First, you must clearly recognize that if you cannot do good you have no business to run the risk of doing serious harm. Secondly, no one should undertake the removal of a foreign body without very careful consideration as to its exact position and relation to surrounding structures. An operation for its removal should never be carried out without an *x*-ray examination, because so often there are multiple foreign bodies or there are concomitant injuries to bones which can be dealt with at the same time. No attempt should be made to remove foreign bodies without careful localization unless they can be certainly felt near the surface. As the foreign body is always potentially a source of infection, the area from which it has been removed should always be drained.

I would also plead for the routine use of the *x* rays even in cases in which the foreign body can be felt, or in which the lesion, whatever it may be, is apparently perfectly obvious. It is wonderful how many revelations one gets, and often in cases in which the injuries have been apparently trivial. Let me tell you of the case represented in the diagram (Fig. 5) which I have made from an *x*-ray photograph.

This man was injured by shrapnel in the lower part of the right thigh. There was a small sinus on the outer side leading to a piece of metal, apparently quite close to the surface. A skiagram of the immediate vicinity only showed a foreign body lying just inside the cancellous tissue of the bone. The problem seemed very simple, and it looked as though the case was almost a trivial one, but on examination I discovered a large hard swelling in the upper part of the inner aspect of the thigh. It was smooth, hard, and scarcely tender, but there was a little increased heat. Had there been no question of injury it would

certainly at first give rise to the suspicion of a sarcoma, or it might have been an enormous gumma. However, an *x*-ray picture of the whole femur showed a crack extending from the point at which the foreign body was impacted half way up the shaft and then across the inner aspect of the bone, the mass being represented by a large amount of callus thrown out about the latter, and probably due to the fact that the patient had not had adequate rest, no serious injury to the bone being anticipated.

Instances of this kind are very common. I would only mention one.

An officer accidentally shot himself with his revolver. The bullet entered over the front of the tibia, 4 in. above the ankle-joint, and a very tender point just in front of the ankle-joint, and apparently not far under the skin, suggested the position of the missile; *x*-ray examination showed that the bullet had really traversed the tibia from just below the wound of entrance to its lower end, producing an amount of injury which would never have been suspected either from the symptoms or from any physical signs.

With regard to the actual removal of missiles I think we have retrogressed a little. In the old days when Nélaton's probe was invented the efforts of the surgeon were almost entirely limited to the removal of foreign bodies by way of the wound of entrance, and this is a method which is still sometimes exceedingly useful. If a foreign body can be easily felt with the probe, and if an *x*-ray examination confirms the position and the fact that it is single, then to remove it through the original track is often a simple matter, and I have several times been successful, especially with the round shrapnel bullets which were so frequent in the early days of the war. It is, of course, sometimes necessary to enlarge the wound of entrance and the aperture in the deep fascia, but nowadays we have the aid of anaesthesia which our forefathers lacked, and this greatly increases the scope of the measures with which they had to be content. If the wound of entrance and the track have healed, then it is often expedient to remove the foreign body by some shorter route, cutting on to it directly.

With deeply situated foreign bodies, and foreign bodies in inaccessible parts you cannot have too much information, and I would urge you never to attempt the removal of foreign bodies without an *x*-ray plate or plates as a guide. Very frequently the radiographer marks the site of the foreign body exactly, and gives an indication of its depth, but without the plate some important point may be missed which may have a great bearing on the success of the operation.

In a case in which a rifle bullet was embedded in a rib, the wound of entrance was on the surface of the back, and close to the point at which the bullet was seen to be lying by the screen. It was accurately localized, and I foolishly attempted to remove it without having seen a plate. To my great disappointment I failed to find the bullet, but at a second operation the knowledge that it was actually embedded in the rib made its removal quite easy.

In our *x*-ray department some simple devices have been found most useful. For instance, it has been observed that when a foreign body is near the surface it can easily be made to move by pressing over its site during a screen examination. We have also found a screwdriver used as a pointer very useful, and wires have been found of value in the localization of bullets in the chest and in the head.

Always beware of making ill-considered attempts to remove small foreign bodies embedded in muscular parts, and indeed they are of minor importance, because they are scarcely likely to give rise to much trouble in such situations.

At the beginning of the war and for some time afterwards foreign bodies in the chest were supposed to be in sacred ground, and patients were universally advised to have them left alone. Being impressed with the amount

FIG. 5.—A diagram made from an *x*-ray photograph. A fragment of shrapnel was lodged at the point A, and there was a large mass of callus at B. The longitudinal fissure was only disclosed on *x*-ray examination, the injury having originally been looked upon as trivial.

of mental anguish which some of these men appeared to endure because of the knowledge that they had a foreign body in their lungs, I have now on four occasions deliberately opened the chest and removed bullets or shell casing, and in each case with complete recovery.

The Need of Ordinary Methods of Examination.

Nowadays, with so many special methods of examination at our disposal, we are all apt to forget the routine plans which have stood us in such good stead for so many years. I have indicated the extreme value I attach to *x* rays, but they should not be used to the exclusion of other and simpler methods of examination. These points were well illustrated in the following cases:

A man who had been wounded in the left side of the back complained of persistent pain on defaecation. There was no wound of exit, and a fruitless search had been made for the foreign body, the whole of the left side of the back and pelvis and all down the left thigh being *x*-rayed. When he came under my observation, in the course of routine examination I palpated the rectum, and found what I took to be the foreign body lying on the right side and within easy reach of the finger. The presence of a shrapnel bullet in this situation was confirmed by the *x* rays, and it was subsequently removed by an incision to the side of the coccyx, with complete relief to the symptoms.

In another case a rifle bullet which entered above the right hip was followed by some paresis of the limbs with retention of urine and incontinence of faeces. It was thought that the bullet had lodged somewhere in the spinal canal, but on careful examination with the screen it was disclosed on the outer side of the left thigh in a position in which it could easily be felt had we examined him systematically with a knowledge of the vagaries of bullet injuries in our minds.

In a similar case the bullet had entered in the middle of the left buttock, and could easily be felt lying just under the skin in the middle of the front of the right thigh.

In traversing wounds of the limbs it is remarkable how blood vessels and nerves can be missed, but it is most important never to assume that these structures have escaped, and to be constantly on the look-out for evidence of injury of nerve or blood vessel.

In civil practice it is unfortunately quite common to see paralysis of important nerves after wounds of the limbs have been dealt with and have healed satisfactorily, and it is well always to make it a rule to examine all the nerves that might possibly be injured. A dropped wrist or foot are usually very obvious, but a lesion of some other nerve with less characteristic symptoms may be overlooked. The same thing applies to the blood vessels, and in the case of a man who was wounded through the calf as well as in the head and knee it was only many weeks after the injury that a systematic examination disclosed a slight swelling of the limb together with a widespread purring hum, which was the only evidence of an arterio-venous aneurysm involving both the posterior tibial and peroneal arteries.

In dealing with possible blood vessel injuries it is also very necessary to re-examine the patients from time to time.

In one case a traumatic aneurysm gave no evidence of its presence until twenty-six days after the casualty. In another a man who was peppered with shrapnel on May 15th was sent to a convalescent home on June 12th, apparently making an excellent recovery from what was considered to be a trivial injury; on June 25th he suddenly developed a large pulsating swelling behind the knee, which proved to be a traumatic aneurysm of the popliteal artery.

The same need of careful examination is exemplified by injuries to the chest. These are commonly thought to be beyond the scope of surgery, and to merit very little attention, but they are all worthy of very careful examination from time to time, and for long intervals afterwards. This is well illustrated by the following case:

The man was shot on May 8th, 1915. The bullet entered in the centre of the sternum, just below the manubrium, but there was no wound of exit. He suffered from shortness of breath and pain in the chest, and for a time had a high temperature. These symptoms gradually improved, and in three weeks he was sent to England. On June 24th he was allowed to go home on sick furlough, and at the expiration of this time rejoined and started work at recruiting. He managed fairly well for a week, and then had to give up on account of shortness of breath. When admitted to the 1st Northern General Hospital careful examination showed very definite signs of an empyema at the left base, from which I removed the bullet; complete recovery followed.

In ordinary surgical practice the best diagnoses are made when time is taken to go carefully into the history, and the same rule applies to military surgery. This was borne out by the following case:

A man was admitted to the hospital because he was supposed to have a bullet in his lung. He had certainly been shot from behind, and had spat blood, but on going carefully into his history he volunteered the information that immediately after the injury he saw the end of the bullet sticking out of the front of the chest like a nipple, though the swelling which followed almost at once pushed the skin away, thus obscuring the protruding missile. In this case the bullet was found lying on an intercostal space just in the position described by the man, and from which it was removed with the greatest ease.

Gunshot Fractures.

In fractures due to injuries by firearms some special points ought always to be borne in mind. The injury to the bone very often bears no sort of relation to the size of the superficial wound, the extent of damage to the underlying muscles, or to the shock of the casualty. For instance, an injury due to a bullet may present only tiny wounds of entrance and exit, and yet the bone may be extensively comminuted; whereas in certain types of shell wounds all the soft tissues may be torn away, leaving the bones bare but uninjured.

Cracks and fissures* are exceedingly common and are frequently very extensive, the whole of the shaft being sometimes involved. With such injuries there may be no deformity, abnormal mobility, or want of alignment, and men may even walk or use the affected limb, and it may not be until there is an excessive amount of unexpected callus that the fracture becomes evident. These considerations make routine *x*-ray examination essential in estimating the amount of damage sustained by the bone. Such examinations are worthless, or nearly worthless, unless photographs are made in two planes.

Extensive comminution is the most characteristic feature of gunshot injuries of bone and may exist both with and without separation of the fragments. A bullet may pass through a bone making a regular trephine opening with or without complete fracture or comminution; or the foreign body may be lodged in the bone or in the neighbouring soft parts. When fragments are driven into the soft tissues they may produce very extensive wounds at the point of exit, and it is these cases which commonly give rise to the stories about the use of "dum-dum" bullets. Sometimes quite a mass of bone may be shot clean away, leaving a gap in the shaft. Splaying out of bone fragments about the track of the bullet is another common feature. The only safe rule is to suspect every case and to make routine use of the *x* rays. In the leg and forearm it is fortunately common to get a gunshot fracture of one bone only so that the other acts as a very good support.

The surgeon must always be on the look-out for concomitant injuries to vessels and especially nerves.

So far as the wounds are concerned, the same principles ought to guide us as in the treatment of compound fractures sustained in civil life. A most important point is to resist the temptation to remove loose fragments (Fig. 6), for there is abundant evidence in surgery to show that bone is the best stimulus to the formation of bone. It is impossible to say how much bone will live or die; that question can only be settled by Nature, and in almost every instance she spares more than one would expect (Figs. 3 and 4).

There is a great temptation to use plates and screws,

* A crack is a cleft whose sides are very near together and can hardly be seen; a fissure is a visible cleft, whose sides are widely separated.—DEFORME.

FIG. 6.—A gunshot fracture in which the comminuted fragments were removed. There was no sign of regeneration six months after the casualty. The gap was subsequently bridged by a bone graft.

but for my own part I have not yet made up my mind that this is good practice in compound fractures; and it will take a good deal of evidence to show that internal splinting is to be accepted as a principle in the treatment of gunshot injuries.

[In speaking of disabilities which might result, Major Grey Turner instanced the following cases:

A man was shot through both bones of the forearm; the fragments united in such a way that he was unable fully to supinate the hand, doubtless because more attention was paid to the wounds than to the position of the bones.

A man had a similar fracture at the junction of about the middle with the lower third of the radius (Fig. 7). In that case the same disability existed, but in an exaggerated degree.]

FIG. 7.—A gunshot fracture of the radius which had been allowed to unite with the hand in the prone position.

It does not much matter how the arm is put up to secure this full supination. It is not a question of some special splint or piece of apparatus but of a principle which must be borne in mind. Personally, I prefer to use two straight splints made of gooching and extending from just below the shoulder to the extremity of the metacarpus. The fixation of the splint to the upper arm secures complete supination of the forearm.

The same thing applies in the case of those fractures at the lower end of the femur in which there is backward displacement, as in the supracondyloid fracture of civil life. The displacement must be met by flexion of the knee; neglect of this precaution, though it may not interfere with union, often gives rise to a very crippling amount of disability in the movement of the joint. Similarly, gunshot fractures of the upper end of the femur ought to be treated with the limb abducted if the best results are to be obtained.

In most cases the principle of extension must be employed, and this more so than in civil life, because so often there is great shattering of the bone or actual loss of substance. To carry this out in the lower limb often causes much trouble, and a great deal of ingenuity has been exercised in the manufacture of apparatus for this purpose. In the upper limb the problem is simpler, and for fractures the weight of the limb can usually be relied upon to secure the necessary amount of extension, and with excellent results. Most of my cases of gunshot fracture of the humerus are treated by suspending the wrist in a short sling, sometimes with the addition of pieces of gooching applied over the seat of fracture and fixed to the chest with a circular bandage.

Bones require rest and time for their repair, and this is especially important in military surgery, where the presence of sepsis so often delays union. Aching and tenderness at the site of the fracture are sure signs that repair is not yet complete and equally certain guides to the necessity of further rest.

Injuries to Joints.

The surprising way in which many of these injuries recover with a good range of movement has frequently been a matter for comment, but nevertheless all cases do not end so favourably. Since it is usually impossible to tell at an early stage of the case whether or not ankylosis will occur, it is very important to deal with these cases in such a way that should such an untoward result follow the limb will be in a useful position. This rule should always be followed whatever the cause of the joint injury, but it is especially exemplified by numbers of cases met with in military practice.

[Major Grey Turner instanced the case of a man who sustained a bullet wound through the elbow-joint, followed by severe sepsis; the arm was treated at a right angle, and, as ankylosis followed, the usefulness of the limb was much interfered with.]

Injuries of the elbow-joint should be treated in a position midway between a right angle and full flexion, for this is certainly the most useful should ankylosis occur. It is then easy to reach the mouth, to brush the hair, to get at the coat pockets, and so on. Such a condition may subsequently be treated by arthroplasty, but it may be that the patient will not submit to any interference or there may be some other reason why it should not be carried out, and therefore it is imperative to treat these joints in the most useful position at the outset. This applies equally to the wrist, for should it become ankylosed neither excision nor arthroplasty gives any certainty of a good result. Cases with shattered joints, such as that shown in Fig. 8, should be put up in the dorsiflexed position, for then the grasp is strong and the hand very useful. If ankylosis takes place with the wrist slightly flexed, as so often occurs, the grasp is very weak indeed. It is easy to test this matter for yourselves, and you will be surprised at the difference the position makes to the usefulness of the hand. If the shoulder is the joint affected the arm should be kept fully abducted, for this materially increases the range of movement obtained through the scapula, and also prevents the annoyance of the arm constantly rubbing against the side.

FIG. 8.—Shattering of the carpus and adjoining parts the result of a gunshot wound. A case to be treated in the dorsiflexed position.

The hip should be slightly flexed and abducted. When the knee is the joint affected it should be kept just a little flexed, while in cases of great destruction of that joint it is most important to prevent the outward and backward displacement which is so apt to occur. When the ankle is involved the foot should be slightly pointed, for this much diminishes the loss of elasticity which a fixed ankle-joint entails.

What has been said about the length of time necessary for recovery in fractures and about the significance of persistent tenderness especially applies in cases of joint injury. My experience has taught me that "more rest and less massage" is a very sound axiom in dealing with joints that have one time been infected. If John Hilton, the gifted author of *Rest and Pain*, could but revisit this globe, he would be delighted to find that the principles he so wisely upheld have stood the test of time.

Injuries to Nerves.

There is great need of care in the treatment of paralysed parts, especially to keep the muscles, whose nerve supply is cut off, in a state of relaxation, so that the recovering nerve will not find them so overstretched that much valuable time is wasted in "taking up the slack." This is best illustrated by a reference to musculo-spiral paralysis, where the dropped hand means harmful stretching of the extensor tendons, easily provided against by the wearing of a simple straight forearm splint during recovery.

The Psychological Factor in War Surgery.

The influence of mind over body is an important factor which is well recognized by all who have to deal with the sick, and it is especially so in our military work. Here we are dealing with men who are frequently a very long way from home and friends; who have suffered the fatigue of war and have often for the first time been introduced to many of the horrors that follow in its wake. These men are not normal in mind—there is often a temporary loss of balance, and it is a wonderful commentary on the amount of backbone possessed by our nation that the wounded are so constantly cheerful and bright in spite of their great trials. But it is most important to recognize this aspect of the matter, and it says much for the wisdom of the authorities that so far as possible they arrange for wounded men to be sent home to England as soon as they are fit to

travel. To be once again in their home-country and within reach of friends does much to help recovery in bad cases. Similarly, the bright surroundings of our hospitals are valuable therapeutic agents, and they ought to be aided by a cheery optimism which I think it will not be difficult for any of you to cultivate. Always remember that one of the most valuable and cheapest remedies we possess is hope.

FURTHER NOTES ON PROTOZOAN INFECTIONS OCCURRING AT THE KING GEORGE HOSPITAL.

BY

H. M. WOODCOCK, AND W. J. PENFOLD,

D.Sc.,

M.B., D.P.H.

(From the Bacteriological Department, the King George Hospital, Waterloo, S.E.)

DURING the last six months the faeces of altogether 384 different cases have been examined for protozoan parasites. The findings obtained are set out in the following table, from which it will be seen that 98 cases have shown one, sometimes more than one, of the protozoa tabulated; the proportion of positives is 25.5 per cent. of the whole. *Blastocystis* has been omitted; if this form had also been included, the total would have been considerably greater. We have omitted it, however, not because we do not consider it a protozoan, but because it occurs so generally that we have ceased to record it in the ledgers; in nearly all the stools, although no other parasite may be present, a few *Blastocystis* individuals can be found if particularly looked for. Certainly as a general rule this organism does not appear to have the slightest pathogenic effects. The only case in which it was apparently the cause of diarrhoea has been that referred to in a previous note;¹ from this patient no other pathogenic organism was recovered.

Table of Cases Examined, showing those Infected with Protozoa.
(Total Cases, 384.)

	No. of Cases.	Percentage of Total.	Percentage of Positives.
Infected with Protozoa ...	98	25.5	
FLAGELLATES:			
<i>Lamblia</i> ...	22	5.7	22.4
<i>Trichomonas</i> ...	14	3.6	14.3
<i>Macrostoma</i> ...	11	2.8	11.2
ENTAMOEBAE:			
<i>E. coli</i> ...	57	14.8	57.1
<i>E. histolytica</i> ..	1	1.0	1.3
Coccidia:			
<i>Isospora</i> ...	10	2.6	10.2

* This is inclusive of one case of liver abscess, in which the parasites were recovered only from the wall of the abscess.

Nearly all the cases have been examined, of course, two or three times, often more. With rare exceptions, the first examination has revealed the presence of the particular parasite (or parasites) occurring; in one or two cases of a very scanty *E. coli* infection the cysts have been noticed first at the second time of examination. Practically all the infections have occurred in men who had been at Alexandria (or elsewhere in Egypt) and Gallipoli; a *Lamblia* infection was found, however, in a patient who had been only on the French front; this man had in all probability contracted the infection from association either with French colonial troops or with Indian regiments. A case of relapse of amoebic dysentery, after a long interval, occurring in France is noted below. As has been pointed out recently by Ledingham and Penfold,² we have not obtained any definite indication of a relation between the occurrence of bacillary dysentery or typhoid disease and the presence of a protozoan infection in the intestine.

From the table it will be seen that *E. coli* has proved the commonest of the parasites enumerated, occurring in 14.8 per cent. of the total number of cases and in more than half of the total positives. *Lamblia* has been the next

most frequent, but this form has been found in only 5.7 per cent. of the total number of cases. The other flagellates have been less frequent. The view taken by one of us in a preceding note with regard to the coccidian found, in which it was considered to be probably an *Isospora*, has been fully confirmed by Wenyon.³ The coccidian of the genus *Coccidium* itself, which has since been found by Wenyon,⁴ has not been seen in any of our cases. (It may be pointed out that *Coccidium* differs from *Isospora* in forming 4 spores in the cyst (oocyst), instead of 2, as in *Isospora*; but, on the other hand, the former genus has only 2 sporozoites (germs) in each spore (or sporocyst), instead of 4, as in the latter.) In all the 10 cases in which *Isospora* has occurred the number of the parasites in the faeces has been scanty, and there has been no sign of pathogenicity in connexion with their presence.

AMOEBIC DYSENTERY (AND LIVER ABSCESS).

The *Entamoeba* of amoebic dysentery and liver abscess, generally regarded as *E. histolytica*, has been found, in one form or another, in 8 cases, all of these occurring since our first note was published. Certain of these cases are worthy of brief mention.

Convalescent Amoebic Dysentery.

Case 1.—The patient gave no agglutination reaction to Shiga's bacillus. On two occasions, in loose brown stools (after a saline purge), scanty, active *histolytica* forms, of typical character and with one or two containing red blood cells, were found. No cysts were seen and later examinations were entirely negative, both as regards active forms and cysts. This patient had received daily emetine injections for a week prior to the first observation of the amoebae.

Liver Abscess.

Case 2.—The patient had chronic diarrhoea and the stools were usually thin and clayey-yellow in colour. In the first stool examined numerous *Trichomonas* were present; these parasites were also found subsequently, but only once, for some reason or other, although the stools were well examined several times. On no occasion were *Entamoebae* found, whether *histolytica* or *coli*, either active or encysted. Nevertheless, from the wall of the abscess typical active forms of *histolytica* were obtained. It may be pointed out that the blood count of this patient showed no leucocytosis.

In the remaining cases cysts only have been found (up to the present).

No History of Dysentery.

Cases 4 and 8.—These cases are instructive because no history of true dysentery can be elicited. In Case 4 the patient gives a history of diarrhoea (four or five stools a day) for about a week while in Alexandria, at the beginning of September; but no blood or mucus was noticed. He did not report sick at the time, and is positive he had no emetine injections, then or later. He was sent to Gallipoli, whence he was almost immediately invalidated as suffering from enteric. Dr. J. D. Thomson, of the bacteriological department here, informs us that this patient gives no agglutination reaction either to typhoid, paratyphoid, or bacillary dysentery.

Case 8 also gives no history of blood and mucus, or even of marked diarrhoea. During August, while at Suvla Bay, he remembers occasionally having four or five stools a day; he never had any treatment. The patient subsequently developed jaundice, and later nephritis, on account of which he was sent home.

Both these cases were found on examination to be passing large numbers of *tetragena* (*histolytica*) cysts and no *E. coli* cysts.

Relapses of Old Amoebic Dysentery.

Case 6.—This patient had been in India for several years, during which period he had three attacks of dysentery (presumably amoebic). The last occurred at the end of 1909, just before his return to England; the patient states that he had on this occasion four injections (? of emetine). Last October, on the French front, he had dysentery, with blood and mucus for twelve days. He was invalidated to a base, where he received one injection of emetine. His condition improved, but diarrhoea continued intermittently, and he was sent home to a provincial convalescent hospital. While on leave in London he had a return of blood and slime on one occasion and reported sick at this hospital.

In this case, we have to deal, in all probability, with relapses of the old amoebic dysentery, after an interval of six years. This patient's serum also gives no indication of typhoid disease or bacillary dysentery.

The incidence of the cases of amoebic dysentery in this hospital up to the present has been most interesting in relation to the occurrence of cases of bacillary dysentery, and well illustrates the liability to error of random sampling on a small scale when attempting to obtain any idea of the general numerical ratio between the two types. Up to the middle of last December the first two cases referred to above were the only cases showing *E. histolytica* in any form which came into the hospital, while

during the same period, out of a sample of 103 cases examined by agglutination, 47.5 per cent. were found to be *B. dysenteriae* (Shiga) infections. Unfortunately we had no means of knowing whether any of the cases received into the hospital whose stools were negative in respect of cysts had had amoebic dysentery and completely lost the parasites—that is, had not become cyst carriers. In this connexion we can only point out that certainly four of our cases received emetine injections, two of them eight or nine doses, and were nevertheless not freed from the parasites and those who were not treated at all are very heavy cyst carriers, although two of them do not appear to have had well-marked dysentery.

The six cases of cyst carriers have all entered the hospital since the middle of December, most of them within a very short period of each other. Dr. Thomson has kindly done the agglutination tests of these six cases against the chief members of the dysenteric and typhoidal groups. He finds that in only one case (that described more fully below) is there a probable indication of an infection with *B. dysenteriae* (Shiga). The patient's serum agglutinated ++ at 1 in 50, definite trace at 1 in 100. In another case of amoebic dysentery, however, which was specially transferred on our account to this hospital, just before we had the above succession of cyst carriers, and which is not included in our own list, there is clear evidence of an infection with Shiga in addition to amoebic dysentery, this patient's serum agglutinating +++ at 1 in 50, ++ at 1 in 100, trace at 1 in 200. It is worth noting therefore that out of 59 known cases of either amoebic or bacillary dysentery, only in one or, at most, two cases can we say definitely that both types have occurred together.

Occurrence of *Entamoeba* "minuta."

In one of our cases of cyst carriers the cysts have been markedly different from the usual type of *E. histolytica* (*tetragena*) cyst. The patient had been in India for seven years, but states that he never had dysentery or malaria while there. He gives a history of dysentery occurring

FIG. A.—*Entamoeba minuta* (from stained preparations). 1, Form preparatory to encystment. 2-6, Cysts with varying number of nuclei.

last September, while at Gallipoli. He had diarrhoea for two days, then blood and mucus for four days, the diarrhoea continuing subsequently for nearly a month. He received eight injections of emetine, one daily. He considered this did good. On two successive examinations of the stools, towards the end of last December, the cysts mentioned were found. The patient then had four injections of emetine, after which no cysts were again found until January 19th, when a few were present in the stool.

The most striking character about the cysts is their uniformly small size. They are generally spherical, from $7\frac{1}{2}$ to 8μ in diameter, but occasionally are slightly ovoid, about 7 by 8μ ; we have never seen any cysts larger than 8μ at any examination of the stools. The cysts have a greenish, rather refractile appearance, and in the fresh condition no definite internal structure or nuclei can be made out. The cyst membrane is thin and does not show a double contour. After adding iodine solution one or two nuclei can usually be seen, and the chromidial blocks or

masses, when present, generally take up the stain also, but these masses do not stand out so conspicuously in these cysts as do the chromidial bars in typical *histolytica* cysts. In permanent preparations stained with iron-haematoxylin the cysts show nearly always one (Fig. A, 2) or two nuclei (Fig. A, 3-5); only in a single instance (Fig. A, 6) have we found a cyst with four nuclei, although the preparations have been well searched. (In the figures the chromidial blocks or masses are stained up intensely.) Fig. A, 1, shows an early stage in the encystment of this form. In addition to its smaller size, the nuclear character differs apparently from that of the nucleus of the cyst-producing, "*tetragena*" phase of *E. histolytica* in not showing a ring-like karyosome with a contained centriole-like body.

James, in a recently published excellent account of the *Entamoebae* of the Panama Canal zone,⁶ describes the occurrence of what is undoubtedly the same form, and his figures closely resemble ours. James thinks that this *Entamoeba* represents the *E. minuta* originally described by Elmassian. We do not feel at all certain as to this, because the dimensions given by Elmassian for the cysts agree with the usual size of *tetragena* cysts, and are distinctly larger than those found either by James or ourselves; but we retain, provisionally, the same *minuta*. James is inclined to consider this form as associated with a mild type of amoebic dysentery, and concludes that if *E. minuta* is a phase in the cycle of *tetragena* it is a very well defined and singularly distinct phase, and its inclusion in the *tetragena* (*histolytica*) species will necessitate the relinquishing of several criteria now in use for classification.

We ourselves think it is quite likely that this form is really distinct from *E. histolytica*+*tetragena*, and constitutes a third, independent form of *Entamoeba* occurring in man, either a distinct species or else a distinct variety. With one exception all our cyst carriers are well in the post-dysenteric stage of the disease; but they are all passing the typical *tetragena* cysts. We have never found a *tetragena* cyst less than $10\frac{1}{2}\mu$ in diameter, though slightly smaller ones are stated to occur occasionally. But when they do, they are always associated with cysts of the normal size. The vast majority of the cysts we have seen have not varied more than 1μ from 12μ in diameter. On the other hand, on no occasion have we found a *minuta* cyst larger than 8μ . We do not lay any stress on the rarity of the occurrence of cysts with 4 nuclei, because it occasionally happens that in preparations of *tetragena* cysts, the great majority found have only one or two nuclei. It may be, perhaps, more usual for the cysts of this *minuta* form to be passed in the earlier stages of development than it is in the case of *tetragena*. (The size of the cyst is the same, of course, in the 4-nuclear stage as it is in the 1 or 2 nuclear stage.)

In what relation this form stands to the production of amoebic dysentery—for example, whether it produces a mild type only—we are not able to say from the evidence so far available; because, as stated above, this particular case showing these cysts may have had bacillary dysentery as well. It may be pointed out, however, that, even if this is so, there is no reason to suppose that the characteristic small size of these cysts represents an abnormal phase—for example, due to the simultaneous occurrence of bacillary dysentery—since the special case, not included in our own series, where there is undoubted evidence of Shiga, is passing the typical *tetragena* cysts. It is probable that this *E. minuta* is also affected by emetine, because of the cessation of the appearance of the cysts in the stools for more than a fortnight after four doses had been given. We consider it is important to draw attention to these small cysts, in view of their possible further occurrence, since they are quite likely to be overlooked, or at all events regarded as having nothing to do with *E. tetragena* cysts, or with amoebic dysentery.

THE TREATMENT OF LAMBIA INFECTIONS.

There is no doubt that heavy *Lambdia* infections are often distinctly pathogenic, being the cause of marked diarrhoea. This may be intermittent, or cease for a period, but is very liable to recur owing to exposure, indiscretions in diet, and so on. A *Lambdia* infection is apparently more active, and the cause of greater intestinal derangement in warmer countries, for example, the Mediterranean

area. Men now in England with a heavy, persistent infection, even though no longer inconvenienced by diarrhoea, would be extremely likely to suffer from a return of the complaint on proceeding again to a warmer climate. Of the 22 cases in which *Lambia* has been present in the faeces, at least 6 have been very heavy infections. One instance has been already given in our previous note. Another case has been in the hospital for more than four months, and during this period every examination of the stools has shown enormous numbers of cysts, with, now and again, when the stool was very loose, many unencysted (active or inactive) forms in addition. Several efforts have been made to get rid of these troublesome parasites, but up to the present, unfortunately, we cannot say that a specific mode of treatment has been found. To certain of the resident medical officers, especially Drs. G. Dawson and F. J. McCarthy, who have been in charge of most of the cases concerned, we are greatly indebted for their cordial co-operation in these attempts.

Treatment.

The varying success obtained with different drugs may be briefly indicated.

The first case in which the parasites were found was also a case of bacillary dysentery. *Lambia* occurred in enormous numbers for a period of about a week. The patient was given beta-naphthol 15 grains, with bismuth salicylate 20 grains, thrice daily, for some days. By the end of three weeks from the time of the first observation not a single flagellate or cyst was any longer to be found. Owing to other causes, this patient has remained in the hospital for six months; during this time the stools have been examined on several occasions, the last examination having been made only a few days ago. No sign of a flagellate infection, whether of active forms or cysts, has been again found. We may regard this case, therefore, as having been probably cured by the mixture.

Two other cases were treated with turpentine (térébenthine), following the opinion of various French workers as to its value. The dose was 10 minims, three times a day, for four or five days. This was followed by guaiacol carbonate, recommended to us by Dr. Thomson, 5 grains thrice daily, for a day or two before the stools were examined, but probably not long enough to have much effect. When the examination was made, in one case no cysts were found; in the other, after much searching, a few dead looking cysts were seen. Four days later both stools were again examined, and in neither case were any cysts found. The patients were then sent out of the hospital. We cannot say, of course, definitely that no recurrence has taken place, but from our experience in the first case we consider this unlikely.

On the other hand, in two other cases, none of the remedies tried up to the present has produced any effect. Turpentine, guaiacol, thymol have all failed.

Beta-naphthol, together with bismuth salicylate, then, appeared to effect a complete cure in the only case in which we have been able, so far, to give the former drug. "Térébenthine," in small doses, for some days, was also apparently successful in two cases, but has failed in two others. We have not yet tried giving this drug in a single large dose.

MALARIA.

Altogether, 14 cases of malaria have occurred in the hospital up to the present. Of these, only two have been due to the pernicious parasite (*Laverania malariae vel praecox*), in which cases both small rings and crescents (gametocytes) were found. All the other cases have been due to the benign tertian parasite (*Plasmodium vivax*). We have had no instance of a mixed infection.

Postscript.—Since sending the above paper to press we have been able to treat another case of heavy chronic *Lambia* infection by the administration of beta-naphthol and bismuth salicylate. The case was that already referred to as having been in the hospital four months, and other drugs had not made any impression on the parasites. The stool was examined a few days ago, after three days' treatment as above. No *Lambia* cysts were found in the faeces. If their disappearance proves to be permanent, as in the first case, a good trial with the combined beta-naphthol and bismuth salicylate appears indicated in cases of heavy *Lambia* infections. We are inclined to think that the bismuth salicylate is at least as important a factor as the beta-naphthol.

SPIROCHAETES AND THEIR GRANULE PHASE.

BY

H. B. FANTHAM, M.A. CANTAB., D.Sc. LOND.,

LECTURER ON PARASITOLOGY, LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

SPIROCHAETES are thin, delicate, undulatory organisms which are widely distributed in Nature. Some of them are free-living and occur in stagnant water or in sea-water. Others live in the digestive tracts of animals, both vertebrate and invertebrate. In man *Spirochaeta buccalis* and *S. dentium* may be found in the mouth and *S. bronchialis* in the respiratory tract, while *S. eurygyrata* and *S. stenogyrata* may occur in human faeces. Also, *S. balbianii* is a well-known species found in the intestinal caecum and crystalline style of oysters and allied Lamellibranchs. Other spirochaetes occur in the tissues of vertebrates, and are often pathogenic. The causal agents of relapsing fever, such as *S. recurrentis* and *S. duttoni*, occur in the blood during the pyrexial periods. Another of these organisms—*S. schaudinni*—is found in tropical ulcers. Yet other spirochaetes, often placed in a separate genus *Treponema*, are the causal agents of syphilis and of yaws, and are known respectively as *Treponema pallidum* and *T. pertenue*.

Probably the longest spirochaetes are among those found free-living. Such an one is *S. plicatilis*, which may reach 200 μ in length. On the other hand, *S. leverani*, found in the blood of mice, is a very short form, and may be only 3 μ long. Spirochaetes may vary from 0.25 μ to 2 μ in width. The outline of the body of one of these Protista is corkscrew-like, and varies in appearance owing to its great flexibility. Quickly moving spirochaetes show many waves of small amplitude, while slowly moving forms present fewer, larger waves of greater amplitude. Hence it will be seen that it is hardly accurate to take as specific characters the number of undulations or coils found in fixed and stained specimens of spirochaetes. The number of turns or waves is, then, more an index of rate of motion—as well as of thickness, which is also a factor—than one of differentiation between various species. Further, owing to the processes of growth and division, the latter occurring by binary fission, there is much morphological variation among spirochaetes. This polymorphism results in differences in length and breadth within the same species, variations which tend to be overlooked unless a large number of specimens from a series of cases is examined and measured.

Internally, spirochaetes possess chromatin bars, rodlets, or granules distributed evenly along their body length. These chromatin granules are seen only with great difficulty in the smaller forms.

Spirochaetes of vertebrates may be transmitted from host to host directly by the contaminative method, or by the intermediation of an arthropod vector. Examples of the former are the causal organisms of syphilis and of yaws, while examples of the latter are the parasites of relapsing and African tick fevers. A consideration of the life-cycles of spirochaetes leads to a discussion of their granule phase, or capacity for "granule shedding," as it has been termed, a most interesting phenomenon around which a certain amount of controversy has centred. There is no doubt that spirochaetes produce such granules; it is only their significance, whether cyclical or degenerative, that is in question.

One of the spirochaetes best investigated with respect to granule formation is *S. duttoni*, which is transmitted from man to man by the tick *Ornithodoros moubata*. The life-cycle of this spirochaete was first outlined by Dutton and Todd in 1907, and was studied in detail by Leishman in 1909-10. Leishman's results essentially were that spirochaetes gave rise by multiple fission to granules or coccoid bodies inside the invertebrate host, and that these granules or coccoid bodies found their way more especially to the Malpighian tubules, gonads, and other organs of the tick. The granules themselves multiplied. The eggs of the female tick became infected with granules, and the progeny of infected females might be born infected. The observations of Leishman have been confirmed and extended by Balfour (1911), Fantham (1911), and Hindle (1911). The organisms investigated were *S. duttoni*, *S. recurrentis*, and *S. gallinarum*, or varieties of the last. The formation of

granules in *Treponema pallidum* and in *T. pertenuis* has been recorded by Balfour, by Ranken, and by Hoffman. It has also been observed in *Spirochaeta bronchialis* by Fantham in 1914-15. Similar multiple transverse fission has been seen in the larger molluscan spirochaetes—for example, *S. balbiani* and *S. anodontae*, by Bosanquet (1911), Fantham (1911), and Gross (1912). It may be mentioned that, even as early as 1882, Zopf recorded and figured the formation of micrococcoid and bacillary forms from spirochaetes of stagnant water and of the teeth, and stated that these forms stand in genetic relationship to one another.

The formation of coccoid bodies, as observed by me in various spirochaetes in fresh preparations, with or without the use of dark-ground illumination, is as follows:

The cytoplasm at first is very finely granular, in fact, almost homogeneous. The chromatin bars appear as minute refractile masses. A concentration of some of the cytoplasm occurs around each chromatin rodlet. These small concentrations gradually become oval, the outer cytoplasmic layer differentiates as a thin coat, and ultimately a series of coccoid bodies or granules is formed, lying usually transversely or slightly obliquely within the periplast sheath. Sometimes the coccoid bodies are set at liberty by a rupture appearing at one end of the spirochaete; at other times, several ruptures, or disintegration of the sheath, can be observed. Stained specimens show a series of darker, lozenge-like coccoid bodies alternating with relatively clear, pale-staining areas. Within the Malpighian or genital cells of a transmitting tick, and in certain mononuclear sputal cells penetrated by *S. bronchialis*, the coccoid bodies often seem to be liberated by the disintegration of the periplast. Groups of coccoid bodies still retaining the outline of the spirochaete from which they originated are of fairly frequent occurrence. When the coccoid bodies are released by a terminal rupture of the parent they tend to form irregular clumps. The progressive elongation of the granules, the assumption of the sinuous form, and the emergence of very small spirochaetes from the groups of granules have been observed in life. It is very probable that there is a definite period in the life of a spirochaete at which there is a marked differentiation of coccoid bodies. It must also be borne in mind that coccoid bodies may be present when spirochaetes as such cannot be detected. At the same time, the finding of chromatinic granules alone is not sufficient to justify the inference that spirochaetosis is indicated, as all such granules are not necessarily spirochaetal in origin. It is essential that motile spirochaetes should be found at some period of the disease, and the developmental stages leading to granules or coccoid bodies observed *in vivo*.

The coccoid bodies have been otherwise interpreted by Marchoux and Couvy (1912-13), Blanc (1911), and Wolbach (1914), who seem to consider these bodies either to be degenerative or to be unconnected with the life-cycle of spirochaetes. According to the first-named investigators, who worked on *S. gallinarum* in *Argas persicus*, the spirochaetes within an infected tick retain their spirochaetal facies, becoming at times so attenuated that they may cease to be visible, some having been observed already on the limits of visibility. Naturally, the question forces itself as to how it is possible to determine the spirochaetal facies if the organism has become invisible. Further, they state that granules occur in the Malpighian tubules, ova, and genital ducts of normal ticks and other arachnids, and that these have been mistaken by Leishman and his supporters for spirochaetal granules. However, it has not been denied that granules may occur in normal tick cells, nor was it asserted that all intracellular granules in infected ticks were spirochaetal in origin, for the granules seen in arachnid cells are not all of the same nature.

Regarding the development of *S. recurrentis* or its varieties in the louse, *Pediculus vestimenti*, Sergent and Foley (1914) state that the spirochaete in the louse assumes a very small form which is as virulent as the spirochaetiform stage. During eight days following a meal of infected blood the body of the louse does not contain any spirochaetes as such, though the spiral organisms reappear later, as was first observed by Nicolle, Blaizot, and Conseil in 1912. Very probably this minute form will be found to be of the nature of a Leishman granule or coccoid body. Also, Nicolle and Blanc (1914) find that the causal agents of relapsing fever are virulent or infective in the louse just before they reappear as spirochaetes. They think that

there is an invisible stage in the life-cycle, though they do not appear to have examined for a granule stage, which might easily be overlooked. Further, it should be noted that in experiments with the invertebrate transmitters of such spirochaetes as *S. duttoni*, *S. recurrentis*, and *S. gallinarum*, careful attention should be paid to the temperature, humidity, and other climatic conditions under which the investigations are conducted, since these factors undoubtedly influence the development of spirochaetes therein.

Granule stages have also been recorded from time to time in spirochaetes in the blood of vertebrates. Thus, Balfour, in 1908, found such bodies in the red blood corpuscles of Sudanese fowls suffering from spirochaetosis. Prowazek, in 1906, recorded intracorporeal stages of *S. gallinarum*. Breinl (1907) and others have observed encysted forms of *S. duttoni* in the spleen, which forms broke into granular bodies that gave rise to new generations of spirochaetes. Sergent and Foley (1914) also found that a minute but infective form occurred in the blood of patients suffering from relapsing fever during apyretic intervals when spirochaetes were absent. Personally, I have seen a very few of these spirochaetes on rare occasions breaking up into coccoid bodies in the blood of the vertebrate host. These minute bodies may appear to occur in or on the red blood corpuscles. They may be found at the crisis and may possibly explain the "after-phase," and may be connected with relapses in the vertebrate host. It is also interesting to note that Sir Patrick Manson, in his well-known book on tropical diseases, writes as follows regarding the etiology of relapsing fever: "Obermeier and von Jaksch describe certain refractile bodies present in the blood during the fever intermissions. The latter author says that he has observed the development of these bodies into short rods, from which the typical spirochaetes are eventually evolved."

Again, the passage of *S. bronchialis* from man to man is most probably by means of the coccoid bodies that leave the human host in the spray with expired air and by way of nasal secretions, as was shown by the present writer in 1914 and 1915. Linen soiled by such secretions, and indiscriminately packed with other soiled clothing, may also aid. Owing to the fragility and short life of *S. bronchialis* extracorporeally, the resistant coccoid bodies in air, dried sputum and dust, and possibly also on the bodies of flies and other insects, are probably instrumental in inducing attacks of bronchial spirochaetosis in human beings, especially those having a lowered bodily resistance, such as after a chill.

A historical interest attaches to the *Cytoryctes luis* of Siegel. These structures are probably explained by the granules shed by *Treponema pallidum* (*Spirochaeta pallida*).

Further evidence for the transition and growth of granules or coccoid bodies into spirochaetiform organisms may be briefly mentioned. Thus, Noguchi (1911), in his paper on the cultivation of *Treponema pallidum*, records in the explanation of one of his figures that "it is not rare to find a round body connected with one or two young *pallida*, as though the latter were just sprouting from the former." Balfour (1913) thinks that he seems to have succeeded in growing spirochaetes *in vitro* from infected tick eggs in which granules only could be demonstrated. Sir William Leishman (1913) repeated many of his former experiments with altered technique, employing dark-ground illumination instead of fixation and staining. He finds that "the granule clumps are not all alike, but that some of them show a much higher degree of refractility than others. Continuous observation of these refractile granules, with the microscope in a thermostat, has further shown me, in the case of two ticks, the definite extrusion of small and actively motile spirochaetes from these granule clumps. . . . After about ten days at a temperature of 28° C. to 30° C., and with a relatively high humidity, some of these clumps give rise to young spirochaetes, which become free, are actively motile, multiply by fission, and may persist in the tissues of the tick for many months."

In conclusion, the value of the recognition of the granule phase in the Spirochaetacea has been strikingly set forth by Noguchi, who, in an address given before the Royal Society of Medicine in London on October 20th, 1913, stated that he "was able to demonstrate . . . granules in the pure cultures of *Treponema pallidum*. This phenomenon, however insignificant it may appear in itself, was destined to furnish a key to one of the most

disputed problems of the past fifty years—namely, the problem of so-called parasymphylis, since it was this very idea that prompted me to undertake to search for *Treponema pallidum* in one form or another in the brains of general paralytics and in the spinal cord from cases of tabes dorsalis." And again, "I was led by the observation that *Treponema pallidum* sometimes assumes a granular form in cultures to re study sections of parietic brains stained for the *pallidum*."

ON THE RELATION BETWEEN THE TERMINAL-SPINED AND LATERAL-SPINED EGGS OF BILHARZIA.

BY LIEUT.-COL. R. T. LEIPER, D.Sc., M.B., R.A.M.C.,
WANDSWORTH RESEARCH SCHOLAR, LONDON SCHOOL OF TROPICAL
MEDICINE; READER IN HELMINTHOLOGY IN THE
UNIVERSITY OF LONDON.

THE final chapters of my report on the investigation into the mode of spread of bilharziosis in Egypt may not be issued for some time yet owing to my continued absence abroad. I have the kind permission of the editor of the *Journal of the Royal Army Medical Corps* to publish now a short summary of the results obtained in so far as they bear upon the etiological relation of vesical and intestinal bilharziosis and the explanation of the position of the spine in the eggs which give rise to these two distinct clinical manifestations of bilharzia infection. This question has been for years the subject of widespread discussion, but hitherto no finality has been reached.

The controversialists have arranged their arguments and facts around two principal theories.

(a) Looss's theory maintains that the terminal-spined eggs are the normal product of impregnated females of *Schistosoma haematobium*, while the lateral-spined eggs are those produced parthenogenetically where males have not developed.

(b) Manson's theory, based upon the constant and peculiar shape of lateral-spined eggs, their peculiarly limited geographical incidence, and their special selection for the intestinal tract, hypothesizes a zoological distinction in the adult parasites.

An examination of the fresh-water molluscs at El Marg during the spring and summer of 1915 showed that three species, *Bullinus contortus*, *Bullinus dybowskyi* (that is, the "*Physa alexandrina*" of Looss), and *Planorbis boissyi*, were infected with certain cercariae, which developed in mice under experimental conditions into bilharzia worms. These worms produced eggs of two kinds—namely, some with typical terminal spines and others with typical lateral spines.

By submitting individual mice, each on one occasion only, for a limited period to infection with the cercariae from single infected molluscs it has been possible to demonstrate that those developing in the *Bullinus* molluscs always produce bilharzia worms which give rise solely to terminal-spined eggs, while those which have developed in *Planorbis boissyi* always become worms which produce solely lateral-spined eggs. In all the experiments males developed and were more numerous than the females.

The cercariae found in *Bullinus*, although very similar to those found in *Planorbis*, showed differences in the suckers, in the relative length of tail, and in other minute points detailed in my final report. The adult worms experimentally reared also showed constant morphological differences. In the worms derived from *Bullinus* spp. the males have four or five large testes and the two lateral gut branches are late in uniting, so that even when mature the worms have a short intestinal caecum. In the female the ovary lies in the latter half of the body. The uterus is very long, voluminous, and contains many terminal-spined eggs, some of which lie in pairs. The yolk glands have a limited range in the posterior fourth of the body. These worms belong to the species *Schistosoma haematobium* (*sensu stricto*). In the worms derived from *Planorbis boissyi* the males are small, and have eight small round testes. The two lateral gut branches unite very early. In some of the smallest specimens found this union had already taken place. The intestinal caecum is correspondingly very long. The female has the ovary in the anterior half of the body. The uterus is very short, and almost invariably there is one egg only at a time in each specimen even when a number have already been laid. The yolk glands are extensive, ranging through the posterior two-thirds of the body along the whole length of the caecum. The eggs always have a lateral spine, the first laid is usually smaller than those succeeding, and the spine is then set almost at right angles to the long axis. Pending a consideration of the claims of other names to priority the specific name *Schistosoma mansoni* may be adopted rightly for these worms. They differ in their adult structure from *Schistosoma haematobium* (*sensu stricto*) more markedly than does *Schistosoma bovis*.

Vesical bilharziosis and Manson's intestinal bilharziosis are therefore etiologically properly regarded as entirely distinct diseases.

IODINE IN TETANUS.

BY
A. T. MACCONKEY, M.B., D.P.H.,

AND

S. S. ZILVA, Ph.D.

(FROM THE SERUM DEPARTMENT, LISTER INSTITUTE.)

WHILE the value of iodine as an antiseptic has recently been the subject of discussion, no reference has been made to the well-established facts that iodine possesses the power of rendering tetanus toxin non-toxic, and that such a modification of this toxin can produce active immunity.

An example of this effect is shown in the first table.

TABLE I.—Results of Injecting Subcutaneously into Guinea-pigs a Mixture, consisting of Equal Parts of Gram's Solution of Iodine and of Tetanus Toxin, some of which had been kept at 36° C. and some at Room Temperature for Different Periods before Injection.

Weight of Guinea-pig in Grams.	Quantity of Mixture Injected.	Time and Temperature.	Day after Inoculation.							
			1	2	3	4	6	10	14	
340	1 c.cm.	2 hrs. at 36° C.	—	—	—	—	—	—	—	—
380	1 c.cm.	2 hrs. at R.T.	—	—	—	—	—	t	—	—
340	1 c.cm.	1 hr. at 36° C.	—	—	—	—	—	—	—	—
365	1 c.cm.	1 hr. at R.T.	—	—	—	—	t	tt	tt	—
340	1 c.cm.	½ hr. at 36° C.	—	—	—	—	t	—	—	—
380	1 c.cm.	½ hr. at R.T.	—	—	—	—	tt	tt	t	—
375	1 c.cm.	½ hr. at 36° C.	—	—	—	—	t	—	—	—
350	1 c.cm.	½ hr. at R.T.	—	—	—	—	tt	t	—	—
355	1 c.cm.	At once	—	—	tt	ttt	+	—	—	—

R.T. = Room temperature.

Of this toxin, $\frac{1}{300}$ c.cm. killed a guinea-pig of about 350 grams weight in four to five days, and it is obvious that the iodine, when mixed with it, had an immediate effect, but not enough to prevent a fatal result. As the period of contact before injection increased, so did the effect of the iodine become more marked, until the mixture ceased to give rise to any symptoms of tetanus.

The immunizing effect of such a mixture is seen in Table II, which gives details of an experiment in which an iodine-toxin mixture was given in repeated doses.

TABLE II.—*Immunizing Effect of a Mixture of Equal Parts of Gram's Solution of Iodine and Tetanus Toxin. The Mixture was kept for Two Hours at 35° C. before Injection Subcutaneously.*

* No further injection; died April 16th. ** Died March 15th

On March 27th guinea-pigs No. 6-10 each received 1 M.L.D. of toxin; the remaining animals, which were quite well (Nos. 11, 13-17, and 19-22), each received 3 c.cm. of iodine-toxin mixture. All the animals remained quite well.

On April 16th ten animals (Nos. 6-11 and 13-16) each received 2 minimal lethal doses of toxin; the remainder (Nos. 17 and 19-22) each received 5 c.cm. of iodine-toxin mixture. All the animals remained quite well.

On May 1st the animals received the following minimum lethal doses: Nos. 6 and 7, 4 doses; Nos. 8 and 9, 6 doses; Nos. 10 and 11, 8 doses; Nos. 13 and 14, 10 doses; Nos. 15 and 16, 12 doses; and Nos. 17 and 19-22, 4 doses. All the animals remained quite well.

On May 17th the animals Nos. 6-14 each received 100 minimal lethal doses, and Nos. 15-22 each received 50 doses. All the animals remained quite well.

NOTE.—The M.L.D. was 0.00006 gram of a dry standard toxin, and was given beneath the skin of the abdomen. The ? refers to animals which, on palpation, seemed somewhat stiff about the shoulders, but showed no definite signs of tetanus. t = Tetanus. + = Death.

A consideration of the table shows that a single dose of the mixture does not produce enough immunity to protect against one minimal lethal dose (1 M.L.D.) of tetanus toxin. Confirmation of this is afforded by other experiments in which 29 guinea-pigs received subcutaneously doses of iodine-toxin mixture varying from $\frac{1}{3}$ c.cm. to 6 c.cm., and every one of them succumbed to 1 M.L.D. of tetanus toxin given from eleven to twenty-six days later. We see further that two doses of iodine-toxin mixture produced active immunity to 1 M.L.D., while three and four doses

protected against two and four M.L.D.'s respectively. It is possible that the immunity produced was greater, but we cannot say so definitely, as four M.L.D.'s was the highest test dose used.

Such observations naturally suggest the thought that iodine might prove of value as a curative agent in tetanus. Auregan (1915¹) published a series of cases in which he had given a 20 per cent. "ultra finely granular oleaginous suspension of electro-chemical 'colloidal' iodine" with beneficial results. He gave it intramuscularly, but does not mention the size of the doses.

As the treatment of declared tetanus cannot be said to be as yet very successful, it seemed desirable to test experimentally the claim made by Auregan for the use of iodine in tetanus. We therefore carried out a number of experiments on guinea-pigs with this object in view.

In these experiments four guinea-pigs were used for each series. The toxin employed was the same standard test toxin as was used in the previous tests, and each animal received 1 M.L.D. subcutaneously. Twenty-four hours after the injection of the toxin only very slight symptoms of tetanus, or none, were to be observed, and therefore it may be said that the incubation period was about one day. The doses of iodine given in each series were 0.2 c.cm., 0.3 c.cm., 0.4 c.cm., and 0.5 c.cm., except in Series 8, when they ran from 0.1 c.cm. to 0.4 c.cm. Each dose of serum contained 500 U.S.A. units of anti-toxin.

When the serum and iodine were inoculated at the same time, they were not mixed before injection, but were given simultaneously in separate places. When an animal received several doses of iodine or of serum, they were all of the same size.

TABLE III.—*Experiment to Ascertain the Curative Effect of a 2.5 per cent. "Colloidal" Iodine Preparation alone and in conjunction with Tetanus Antitoxin.*

Series.	Treatment.	No. of Recoveries, with Doses they Received.	Deaths.
1	Controls; no treatment	None	All within 4 days.
2	Iodine, 24, 43, and 48 hours after toxin	One. 0.4 c.cm. of iodine	3 within 3 days.
3	Iodine, 43 and 48 hours after toxin	One. 0.5 c.cm. of iodine	3 within 3 days.
4	One dose of iodine and of serum, 24 hours after toxin	One. 500 U.S.A. units of antitoxin and 0.5 c.cm. of iodine	3 within 5 days.
5	Serum and iodine, 24 hours, and iodine, 43, 48, 67, and 72 hours after toxin	None	3 within 4 days; 1 within 7 days.
6	Serum alone, 24, 43, 48, 67, and 72 hours after toxin	Three. 500 U.S.A. units of antitoxin	1 within 8 days.
7	Serum alone, 43 and 48 hours after toxin	None	4 within 4 days.
8	Serum and iodine, 24, 43, 48, 67, and 72 hours after toxin	Two. 0.2 c.cm. iodine and 500 U.S.A. units of antitoxin; 0.4 iodine and 500 U.S.A. units of antitoxin	2 within 4 days.
9	Serum and iodine, 43 and 48 hours after toxin	None	4 within 2 days.

A decidedly curative effect cannot be ascribed to this preparation of iodine, though some recoveries followed its administration, for the largest number (3) of animals that survived in any one series was in that which received repeated doses of serum alone; repeated doses of serum together with iodine gave two survivals, while iodine alone was followed by three deaths.

We then experimented with iodargol ("Iode colloïdal électro-chimique, pur et stable"), which is said to contain 25 cg. of iodine in 1 c.cm. All inoculations were made subcutaneously. The toxin was the same as before.

TABLE IV.—Effect of Iodargol. (Six Guinea-pigs, each weighing 340 grams.)

Toxin Injected.	Iodine Injection after 3 Hours.	Day 1 after Inoculation.		Day 2.	Day 3.	Day 4.
		9 a.m.	3 p.m.			
Oct. 27, 1915. 1 M.L.D. 2 15 p.m.	Control; no iodine	—	No iodine	t	+	
" " "	0.25 c.cm.	—	0.25 c.cm.	0.25 c.cm.	t	tt +
" " "	0.5 c.cm.	—	0.5 c.cm.	0.5 c.cm.	t	+
" " "	0.75 c.cm.	—	(H)			
Nov. 5, 1915. 1 M.L.D. 11 a.m.	1.0 c.cm.	—	1.0 c.cm.	1.0 c.cm.	t	+
	5.0 c.cm.	—	No iodine		tt	+

There is little doubt that iodargol had no favourable influence upon the course of the disease.

In other experiments injections of "colloidal" iodine were given before and three hours after the toxin without any beneficial results.

Further, we tested the effect of a preparation of iodine and soluble starch which neutralized tetanus toxin *in vitro*, but it proved quite ineffective as a curative agent. On one occasion the animals did survive, but this result seemed mostly accidental, for the injections were inadvertently made too close together, and the swelling caused by the injection of toxin joined to that due to the iodine, and thus the latter may have come into direct contact with the toxin before it was absorbed. When this experiment was repeated, care being taken to place the injections far enough apart to prevent direct mixing, the result was death of both the animals.

CONCLUSION.

We are forced to come to the disappointing conclusion that iodine injected subcutaneously has no effect upon tetanus toxin which has been also injected subcutaneously in a different place.

We cannot, therefore, hope to influence favourably the course of an attack of tetanus by injections of iodine alone, nor does iodine appear to have any effect in enhancing the power of serum.

It would seem, then, that iodine can only be of use when applied to the infected focus, so that it can come into direct contact with the toxin before absorption.

THREE CASES OF ABDOMINAL GROWTHS PRESENTING VERY UNUSUAL CHARACTERS.

By CHARLES A. MORTON, F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL; SENIOR SURGEON
TO THE GENERAL HOSPITAL, AND THE CHILDREN'S HOSPITAL.

CASE I.—*Tumour Composed of many Hydatid Cysts Growing within the Abdomen, and Protruding into an Umbilical Hernia so as to form a Large Pendulous Growth.*

A WOMAN, S. H., aged 39, was admitted to the General Hospital in April, 1914, with a very hard, heavy, lobulated

FIG. 1.

mass protruding at the umbilicus (Fig. 1). There were some round elastic nodules on its surface. The umbilicus

was lying on it, and it was sent to the hospital as an umbilical hernia. It measured 7 in. by 6 in. When the patient stood up it hung down (as shown in Fig. 2) so far that the upper surface came as low as the pubes. Because it was so heavy it dragged down the abdominal wall in a funnel-shaped form with it. She always had to support it when her bowels acted. A number of firm round nodules could be felt extending from it, up under the abdominal wall. It was clearly not a simple umbilical hernia, but some form of growth, perhaps extending into the sac of an umbilical hernia, but the nature of the growth was not suspected.

FIG. 2.

At the operation on April 14th I found there was an umbilical hernia, and that a very thick mass of omentum passed out of the abdomen into it. To the distal end of this, lying in the hernia, a large lobulated tumour was attached. The abdomen was full of cysts, some quite small and others the size of duck's eggs. They occupied every part from the pelvis to the diaphragm, some lying under the stomach. I was able to divide the omentum, connecting the colon and the cysts within the abdomen with the umbilical tumour, and then removed the tumour mass with the overlying skin, and brought the edges of the umbilical opening together by the overlapping method. The umbilical tumour weighed 3 lb. 8 oz., and was composed of a number of the same kind of cysts as those within the abdomen, fused together. I found they were typical hydatid cysts. The patient made a good recovery, and returned to South Wales. In answer to a letter of inquiry as to her present condition sent last July, the only information she supplied, with regard to her abdominal condition, is contained in these words: "I am getting on all right, and don't feel no ill effects in the stomach."

CASE II.—*Sarcoma of the Small Intestine causing Recurrent Attacks of Obstruction.*

A woman, R. S., aged 44, was sent to me at the General Hospital in October, 1914, by Dr. Graham, of Watchet, with recurrent attacks of abdominal pain. She had the first attack two years before I saw her, the second one year before. For some time before I saw her she had been getting the attacks every few days. In April she had a very severe one, lasting several days, and requiring hypodermic injections of morphine. All the attacks, even the one two years before I saw her, were of the same character; the pain was either just at the umbilicus or close to it, and was usually most severe at the umbilicus. It was of a gripping character, and after lasting some hours she generally vomited, and then the pain either diminished or ceased. She said she was generally distended when in pain. She suffered from habitual constipation, but for some time she had had no action of the bowels without aperients or enemata. The vomit was bile, and there was no history of either haematemesis or melaena. For a month before I saw her she had been on liquid diet only, with the exception of a small quantity of bread, but had had severe attacks every few days. When she had been taking ordinary diet the attack used to come on two or three hours after dinner.

On admission there was nothing abnormal to be made out in the abdomen, but when seen in an attack of pain I found considerable distension in the lower abdomen, and once I could make out a distended coil. I thought the attacks were due to intestinal obstruction, probably from adhesions. I operated on October 20th, and found the obstruction due to a growth in the small intestine. The coil containing the growth was lying quite free in the pelvis. It must have been about the middle of the small

intestine, for after tracing the gut in each direction from it I failed to arrive at either the caecum or the duodeno-jejunal junction. The bowel on the proximal side was greatly dilated and thickened. The growth was hard and at parts leucoplakic in appearance, and was spreading into the mesentery. It resembled a very large reel, for it was constricted in the centre and had a kind of rim where the bowel wall joined it, just such a rim as one makes on tying the rubber tube on a Paul's intestinal glass tube. It occupied $2\frac{1}{2}$ in. of the bowel and was 2 in. in thickness. There were no secondary growths in the liver, nor any glands in the pancreatic region, but there were a few quite small glands clustered together at the root of the mesentery corresponding to the growth, and a few in the mesentery between these and the growth. Those lying quite close to the growth were removed with it, but microscopic section, made at a later date, did not show any growth in them. I resected the growth, together with 3 in. of the intestine above and below it, and united the ends, and then brought the united bowel through the opening in the parietal peritoneum, the edges of which I united to it, so as to exclude it from the general peritoneal cavity in case of leakage. This, of course, prevented my uniting the deep abdominal wall in the part corresponding to the protrusion of the united bowel, and she will have to guard against extension of the ventral hernia thus produced, by a belt; but by fixing the united bowel in this way outside the peritoneal cavity the serious danger of the operation—that is, leakage from the junction—was avoided. I put a drainage tube by the side of the bowel. There was never any leakage, and she made a good recovery, but during the first few days after the operation she had attacks of abdominal pain, evidently due to obstructed passage of intestinal contents through the united portion of bowel.

The growth was semitranslucent, white and firm, and at its junction with bowel lumen protruded into it like the os uteri into the vagina. The lumen through the growth was so greatly narrowed that only a small pair of

FIG. 3.—This figure shows the interior of the bowel, which has been laid open by a longitudinal cut extending also through the growth, and is spread open. The difference in size of the bowel on the proximal and distal sides of the growth is well shown in the illustration.

artery forceps could be passed through it (see Fig. 3). Microscopical section of several parts of the growth showed round celled sarcoma.

CASE III.—*Malignant Growth of the Colon causing Obstruction, and Associated with Phthisis in a Young Man of 21.*

H. W. was sent to me on October 26th, 1914, at the General Hospital, by the late Dr. Eglington of Street. He had had pain in the left side of the lower abdomen and in the epigastrium for two months, and a small lump had been observed in the left lower abdomen. He had been in a sanatorium for some time, but a week before I saw him

his bowels had ceased to act and he began to vomit, and he was then sent home from the sanatorium to the care of Dr. Eglington at Street. He had had repeated enemata without effect, and the abdomen become distended, and during the twenty-four hours before admission the abdominal pain became very severe. On admission there was considerable abdominal distension, and a small hard lump about the size of a finger-tip could be felt in the left lower abdomen, just above the middle of Poupart's ligament. It was fixed, but fairly superficial. There was a distended coil in the right lower abdomen. No swelling could be made out on rectal examination. There were no physical signs of disease in the chest. The pain had ceased, and he did not vomit. He was fed on albumin water, and had several hot turpentine enemata, and as a result of these he passed a considerable amount of flatus, and the pain did not recur to any extent, nor did he vomit. The distension considerably diminished, and the lump in the left lower abdomen became more distinct. As, however, by the 30th no faecal action had been obtained, I felt obliged to operate. I expected to find—what had been diagnosed before admission—a tuberculous lesion causing the obstruction.

On October 30th I made an incision through the middle of the left rectus, low down. There was a little clear serum in the peritoneum. Two inches of the iliac colon were converted into a hard, smooth cylinder, with a white scar-like appearance of the peritoneum covering it. There were a few yellow nodules on it, and a thickening of the fatty tissue attached to it. It was movable on the floor of the iliac fossa, and the surrounding structures were not adherent to it. It was not at all like a constricting carcinoma. The yellow nodules on it were not like caseating tubercle; they were more of a golden colour, and may have been altered fat. I could not decide whether the lesion was tuberculous or new growth. I could easily have excised it, and should have done so but for the additional disease present. This consisted of hard nodules attached to the transverse colon, and the parietal peritoneum about the head of the caecum. I could not very well reach the liver, but felt no nodules on it, and there were no enlarged glands. I anastomosed the ileum to the pelvic colon. The descending colon was much thickened, but not greatly dilated. During his recovery from the operation he began to cough, and physical signs of effusion appeared at the right base, and an exploring syringe discovered pus there. During this time he had moderate evening pyrexia, and rapidly lost flesh. He had no recurrence of the intestinal obstruction, but had some incontinence of faeces. On November 22nd, having withdrawn an exploring syringe barrel of pus from the chest, I endeavoured to evacuate the pus, but opened into a small shut-off space in the pleura, and could not get the exploring syringe through this into any collection of pus. He died the next day. It was not obvious at the operation why I did not open into the empyema, from which I had just withdrawn the pus; but the necropsy showed that at the exploration the needle had passed through a space of unaffected pleura which had been shut off by localized adhesions and a thin layer of collapsed lung, and into this space I unfortunately opened at the operation, and failed to reach the pus again by the exploring needle passed from it in various directions.

The necropsy also showed that there was extensive breaking down tuberculous disease of the base of the lung, on the side of the empyema, and tubercles were scattered throughout both lungs. In the abdomen were some breaking down nodules on the mesocolon of the transverse colon, and many nodules in the omentum, but no general tuberculosis of the peritoneum, nor any peritonitis, except that old adhesions were present around the anastomosis; and there was not as much as an ounce of fluid in the peritoneal cavity, and this was clear serum. The lumen of the iliac colon was so reduced that I could not pass my little finger through it. The enlargement of this portion of the iliac colon seemed to be due to great thickening of the coats, and the edge was well defined. Both the muscle coat and the mucous membrane were each one-third of an inch in thickness. The thickened mucous membrane formed an irregular raised edge at its junction with the healthy bowel, and here the mucous membrane was puckered. The surface was not ulcerated but smooth, but not as smooth as healthy mucous membrane. There

were no enlarged glands. Professor Walker Hall investigated the nature of the lesion, and has been good enough to allow me to publish his report, which is as follows :

The mass consists of carcinomatous tissues.

The submucous, muscular, and subperitoneal tissues are invaded by glandular cells arranged atypically.

In places the infiltration is so marked that individual bundles of muscle fibres are separated by masses of cancer cells.

The cells themselves show colloid degeneration, and this process is general throughout the specimen.

There is evidence of spread by lymphatic vessels.

BLOODLESS OPERATION FOR HAEMORRHOIDS AND PROLAPSUS ANI.

By MAJOR F. MCKELVEY BELL, M.D.,

SURGEON TO — CANADIAN STATIONARY HOSPITAL, FRANCE, AND
ST. LUKE'S GENERAL HOSPITAL, OTTAWA, CANADA.

The operation here described is intended for cases in which four or more large piles occur or in the milder grades of prolapsus ani. In other words, it may be used in any case in which Whitehead's operation is indicated, but has the advantages of being almost bloodless and less liable to complications.

The usual preparation is given by mild laxatives and a light diet for two days previous to operation, *ol. ricini* 3 j and no supper the evening before, and two to three simple enemata—that is, sufficient to clean the colon—in the morning. The instruments required are one large slightly-curved clamp, two Hagedorn needles, one semi-curved needle, one pair of scissors curved on the flat, tissue forceps, thermo-cautery, and No. 4 silk for suture.

Operation.—After dilatation of the sphincter, a long silk suture is passed through at the junction of the skin and mucous membrane in the mid-perineal line (Fig. 1). This suture is to be left untied and used as a retractor (1), two similar sutures are inserted on either side of the anus (2 and 3), so that when traction is made upon all three

FIG. 1.

the extruded mucous membrane is converted into a triangle.

Each side of the triangle is to be dealt with individually. The portion between 1 and 2 is clamped in order to mark the area for excision. This area is limited externally by the junction of the skin and mucous membrane, and extends internally to within one-eighth inch of the required depth. On removal of the clamp a bluish furrow will be seen, the inner and outer borders of which mark the area for suture.

The two Hagedorn needles are now threaded at either end of a continuous silk suture. The first stitch, which

FIG. 2.

may be inserted before removal of the clamp, is placed at the apex of the triangle, and is tied at the centre of the thread. The clamp being removed the two needles are passed through from opposite sides at the same point—a cobbler's stitch (Fig. 2). Each stitch is pulled taut but not tied. The suture is continued in this manner at $\frac{1}{2}$ in.

intervals until the lower end of this side of the triangle is reached, where it is tied. With the scissors the redundant tissue is now clipped away at a distance of one-sixteenth of an inch from the line of suture (Fig. 3). The narrow ridge thus left is lightly touched with the thermo-cautery. The other two sides of the triangle are similarly treated, and the traction sutures are removed.

FIG. 3.

A suppository containing 1 grain ext. opii is inserted, and the usual rubber tube ($\frac{5}{8}$ by 3 in.), wound with iodoform gauze and well anointed with vaseline, is introduced (Fig. 4). This tube is left *in situ* until the morning of the fifth day after operation. The patient is kept on fluids for four days, and the bowels are constipated with pil. opii gr. 1 to 2 daily. At the beginning of the fifth day 1 oz. of castor oil is given by the mouth, and after four hours 6 oz. of warm olive oil is injected through the tube, which is then gently removed.

FIG. 4.

In a series of twenty-one cases this operation has given satisfactory results.

I am indebted to Sergt.-Major H. E. Law (W.O.), C.A.M.C., for the drawings illustrating this article.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF PUERPERAL SEPTICAEMIA TREATED BY INTRAVENOUS INJECTION OF EUSOL.

To the perusal of the article, "On a case of septicaemia treated by intravenous injection of eusol," by Drs. Lorrain Smith, James Ritchie, and Theodore Rettle, which was published in this JOURNAL on November 13th, 1915, we feel indebted for the successful treatment of the following case:

Mrs. C. H., aged 19 years, a primipara, was delivered of a male child on January 21st, 1916. The labour was very difficult, and was terminated by forceps under chloroform. Owing to the large size of the child, which weighed 10 lb., there was considerable laceration of the vagina and perineum.

On the third day after confinement the temperature was found to be 101°, while the lochia were very offensive.

The stitches were removed, the raw surfaces painted with pure phenol, and the vagina and uterus were douched with mercury biniodide solution (1 in 2,000), and aspirin in 10-grain doses every three hours administered.

On the evening of the same day the patient had a very severe rigor, lasting for two hours. Next morning the temperature had risen to 103.4° and the pulse was 132. The same local treatment was carried out, and next morning 10 c.cm. of polyvalent serum were injected; this dose was repeated the following day. Notwithstanding this the patient's condition became steadily worse.

On January 27th 120 c.cm. of eusol in normal saline, warmed to 37° C., were injected into the right median basilic vein, under local anaesthesia (1 per cent. solution of quinine-urea hydrochloride). Mr. A. G. Francis, Surgeon to the Hull Royal Infirmary, performed the operation.

Several hours later the patient became very restless, and complained of great pain in the back. A hypodermic injection of morphine $\frac{1}{2}$ grain, with atropine $\frac{1}{16}$ grain, hyoscyne $\frac{1}{16}$ grain, and strychnine $\frac{1}{32}$ grain was accordingly given; sleep supervened in a few minutes and continued for several hours. Next morning the pain had entirely disappeared and the temperature had fallen 1.5°. Two days later it registered 99.4°, and reached normal on February 1st. The pulse, though still rapid (over 100), had greatly improved in quality. Previously of extremely low tension, it had now the character which an eminent French clinician so graphically described as *bien frappé*.

The local treatment adopted subsequent to that already described consisted in twice daily douching the vagina

with 1 per cent. solution of lysol and insufflating iodoform. Improvement was steadily maintained, the patient being able to leave her bed four weeks after the date of confinement.

CRANIAL TUMOUR (? DERMOID BY IMPLANTATION.)

PRIVATE R. T., No. 9441, was stunned by the explosion of a shell on April 29th, 1915. A blunt body must have struck the skull, for the skin was slightly wounded; it healed in a few days, but a tumour rose up within five days, and early in May was about the size of a medium-sized orange. Though he had a sense of pressure inside his head, he does not think the tumour itself had pulsation in it at that time. About June a skiagram was taken, and a fracture of the skull was seen at the edge of the tumour. Operation was declined.

I saw the patient in October, 1915, and at first thought the swelling was a meningocele which had become shut off by healing of the fracture. It was round and fluctuating and free from pulsation or expansion on blowing efforts. It had previously been diagnosed as hernia cerebri by another surgeon. At this time I did not think it wise to operate.

The patient was sent to Colchester. A radiograph taken there plainly showed the old fracture of the skull at the edge of the tumour. Having concluded that the cyst must now be shut off from the brain I decided to operate, and on November 29th an incision was made and the whole cyst was shelled out clean. It had no brain connexion. It peeled off from the bare bone in the centre over the bregma. The fracture lay an inch away. It had upward raised edges, so that some diffused pressure must have been made elsewhere by the shell explosion, or the body which was driven by it against the skull. On opening the cyst, hair and sebaceous matter was seen, and on the wall were a few white projections but no teeth.

The question then arose whether the cyst was a mere coincidence, or whether skin had been driven in by the shell and caused a tumour by implantation.

The officer in charge of the laboratory at Colchester reported as follows:

Section shows a simple dermoid cyst lined by about three layers of squamous epithelium, on the surface of which is shown sebaceous secretion. There are large numbers of sebaceous glands. It is impossible to say from a section whether it is a traumatic inclusion dermoid or of congenital formation. The site, of course, would give you much information towards settling the point. If it was in the region of one of the sutures it would almost certainly be a congenital one.—WM. L. MACKARELL, Captain R.A.M.C., O.C. Laboratory.

As no tumour was noticed before the injury, and as the cyst was on a suture, it must be concluded that an embryo dermoid must have been incited to grow by the stimulus of the injury.

Up to date—January 20th, 1916—there is no sign of recurrence.

W. LEDINGHAM CHRISTIE, M.D., F.R.C.S. Eng.,
Temporary Lieutenant R.A.M.C.

Reports of Societies.

TREATMENT OF GUNSHOT WOUNDS.

In the discussion at the Harveian Society of London which followed the address by Sir BERKELEY MOYNIHAN, published in the JOURNAL of March 4th, several speakers spoke of the risk of relighting up infection by secondary operations. The opinion seemed to be that such operations should be deferred as long as possible. Mr. CLAYTON-GREENE said that he was not satisfied as to the proper treatment of a small wound discharging pus with a foreign body at the bottom of it. The danger of interference was that of opening up fresh avenues of infection. He thought exploration should be deferred until the streptococcus had been got rid of by prophylactic vaccines and by Bier's method of cupping. Mr. DONALD ARMOUR thought that the ill effects of reopening wounds were associated specially with bone, in connexion with which there was a real danger of reawakening old suppuration. He had been

much encouraged by the results following the use of magnesium sulphate and glycerine in infected cases. Mr. D'ARCY POWER, speaking of dense infiltrating scars the result of prolonged suppuration following extensive laceration of the soft tissues, expressed the opinion that graduated movements by the patient and massage rendered the tissue much more supple, and made excision of the scar undesirable—at least during the earlier periods.

Mr. DUNCAN FITZWILLIAMS and Mr. A. EDMUNDS spoke of the results witnessed in the Mediterranean among the wounded from Gallipoli. Mr. Fitzwilliams said that the hypertonic salt solution had been much used at Malta, but that antiseptics increased the rate of healing. Mr. Edmunds said that chloramine was one of the most valuable additions to the surgeon's kit, but as the supply was limited he had kept it for a difficult class of mouth cases—those in which the palate was badly damaged. He agreed as to the value of the hypochlorite solution if thoroughly applied to all parts of the wound.

Mr. ALEXANDER FLEMING said that when he went out to France he found the clinical appearance of the wounds totally different from anything he had seen in civil practice, and that bacteriologically the difference was just as marked. The wounds in general resembled the foul-smelling appendix abscesses of civil life. The infection was primarily faecal, and the microbes in the early stages were those normally found in the intestine of men and animals—namely, *B. aerogenes capsulatus*, *Streptococcus*, *B. proteus*, *B. coli*, and a number of spore-bearing putrefactive anaerobic bacilli (to which latter the foul smell was due); all of these were found in faeces. In order to trace the source of infection cultures were made from portions of the soldier's clothing, selecting parts remote from the wound in order to avoid contamination from the wound discharge. These were incubated aerobically and anaerobically, and samples showed out of twelve:

- 10 containing *B. aerogenes capsulatus*.
- 5 containing *Streptococcus*.
- 4 containing *B. tetani*.
- 2 containing *Staphylococcus albus*.

The examinations were carried out in November, 1914, when there was much tetanus among the wounded. These experiments showed that the soldier's clothing was the source of the wound infection. Wound infection might be divided into three stages: (1) A gross infection with anaerobic spore-bearing bacilli, producing a foul-smelling sanious discharge, due to the action of the bacilli on the blood clot in the wound; (2) the anaerobic bacilli disappear, and the discharge becomes more purulent, but not as yet like the so-called "laudable pus"; (3) infection with pyogenic cocci. In explanation of the importance of (3) he related the following experiment: Human faeces were planted in blood clot and incubated anaerobically for twenty-four hours. A loopful of this culture was transferred to a second tube of blood clot and incubated like the first, and so on for ten days, in this way reproducing to some extent the wound infection. He found that the early cultures, in addition to *streptococcus*, contained many *B. aerogenes capsulatus*, *B. coli* and putrefactive organisms, and that these became gradually fewer, until after ten days all had almost entirely disappeared except the *streptococcus* and some Gram-positive bacilli called "wisp bacilli," similar to those found in wounds; the tenth subculture had practically the same flora as an infected wound ten days old. While wounds may become serious in the early stages from infection with tetanus, gas gangrene, and septicaemia, the streptococcal infection of the later stages was by far the most serious, for all the septicaemias were due to it. He described two distinct types infecting these wounds: (1) the *Strep. faecalis*, relatively non-virulent, (2) *Strep. pyogenes*; in about one-third of the cases he had found a third—an anaerobic streptococcus—which had caused a rapidly fatal septicaemia in the patient from whose blood it had been isolated in pure culture. His observations on the use of pure carbolic acid, and iodine solution in alcohol, for the primary sterilization of wounds, led him to conclude that the results were no better than had the applications not been used. The later infections of war wounds he considered not essentially different from those seen in civil practice; in both, the streptococcus and staphylococcus played the most important part, the former being the more potent factor of the two. Since 1903 all forms of sepsis had been treated at St. Mary's Hospital with

vaccines, and in a very large number of cases the benefit seen had been obviously due to the vaccines. They increased the antibacterial substances, and he thought that inoculation with small doses of streptococcus vaccine or of "anti-sepsis" vaccine (a mixture of streptococcus and staphylococcus) would be beneficial in the later stages of the wounds, and that two or three inoculations preceding a secondary operation might prevent the recrudescence of the sepsis.

The President expressed his agreement with Sir Berkeley Moynihan's scepticism as to vaccines. He thought that their value when a patient was already suffering from a poison produced by organisms remained to be proved. Mr. CLAYTON-GREEN observed that it was difficult to form an opinion as to the real value of vaccines, because there were no controls. He had recently had two cases of streptococcal infection which recovered comparatively quickly after the use of vaccines; he did not think either of them would have recovered otherwise; but autogenous, not polyvalent, vaccines should be used.

Reviews.

MODERN BONESETTING FOR THE MEDICAL PROFESSION.

MR. ROMER has written an interesting little book of a very practical kind on a subject which should be of much interest to the medical profession. From time immemorial the bonesetter has flourished in our midst; he has scored his successes, and for many and obvious reasons his failures have not received adequate publicity. The failures are due often to the fact that the bonesetter is insufficiently trained to distinguish various forms of arthritis in their earlier stages from joints which are merely fixed by adhesions. The successes are equally the result of a want of experience on the part of the surgeon, which should enable him to distinguish the uncomplicated presence of adhesions. It is rather disappointing in studying Mr. Romer's book—which is entitled *Modern Bonesetting for the Medical Profession*¹—not to find emphasized the fundamental principles which should guide the surgeon in dealing with the doubtful case. Details are given as to how adhesions should be broken, but the value of the book would have been increased had we been told which is the type of joint to be broken down, what are its essential symptoms, which condition we should approach warily and which boldly.

The author describes very graphically the different movements to be employed in the various joints, and makes the interesting observation that in many instances it is not expedient to put an articulation through its full range of movement. This is not usually taught nor often practised, and in those cases in which symptoms recur an incomplete manipulation is generally blamed. The after-treatment by massage and passive movements is very wisely insisted on. Mr. Romer states that rapidity in execution of the movements gives rise to far less after-pain than if the adhesions are broken down by slow and deliberate stretching. An anaesthetic is recommended in order that complete muscular relaxation should be secured.

The book can be recommended as a very instructive and sane presentation of a subject which has a special interest at this time.

TROPICAL DISEASE.

Rural Sanitation in the Tropics,² by Dr. MALCOLM WATSON, will be read with interest by sanitarians everywhere. It is a record of what has been done to make the tropics healthy since mosquitos were incriminated in the spread of important diseases such as malaria and yellow fever. The work is dedicated to Sir Ronald Ross, who has laboured so vigorously in this branch of medicine, and whose original work in establishing the part played by the *Anopheles* in the transmission of malaria may be said to

be directly responsible for the pages under discussion now. After an introductory chapter, two chapters are devoted to British Malaya. Here the able work done by Dr. Watson himself is described—how he dealt with the flat land near the coast, and with the hilly land farther in. The importance of definitely recognizing the species of mosquito that is carrying the malaria of any given place is well brought out. This is essential if the measures are to be successful. Chapter IV deals with quinine prophylaxis in Italy; V with malaria in India; and VI with Hong Kong and the Philippines. Nine chapters are devoted to Panama, one to British Guiana, one to Barbados. There is an epilogue, and its opening sentence may be quoted, since it puts the matter in the proverbial nutshell. "The problem of sanitation in the tropics, like most problems in the tropics and elsewhere, is primarily one of ways and means." To translate this into other words: if plenty of money can be commanded it is possible to do anything, even to the moving of mountains. Granted, however, a plentiful supply of funds, there still remains the question of their proper application, and it is in the description of this that the book will prove so valuable to future workers. The gigantic experiments at Panama are well described. Here the money was ready, but even so the whole undertaking might have failed if Colonel Gorgas had not been given a free hand to expend the funds in the proper way. Dr. Watson brings this out clearly in his book. No engineering skill alone could have succeeded without the help of the sanitarian, and one may also say without a sanitarian of genius. But, after all, the health of rubber estates and small areas in the tropics is as important—at least to the directors and shareholders—as mammoth undertakings like the Panama Canal. How they may secure this by judicious expenditure will be found in the pages of Dr. Watson's work. There is only one word of warning needed, and that is that means which may be quite adequate for one place in the tropics may not equally apply to others, and a somewhat more prolonged visit than Dr. Watson paid to some of the parts he studied is requisite to get a proper understanding of the local conditions which prevail there throughout the year. The book is in many ways a personal record of what Dr. Watson saw—a journal, in fact—and it may confidently be predicted that all who read it will enjoy it as much as the reviewer did. It is a pioneer work, excellently written, and should prove of the greatest value to future sanitarians in all parts of the tropics. Dr. Watson's practical work in Malaya is well known, and his book will undoubtedly add to his reputation.

Part III (*Ixodidae*) of *Ticks: a Monograph of the Ixodoidea*³ appeared last October (1915). This deals with *Haemaphysalis*, and is by Professor G. H. F. NUTTALL and Mr. CECIL WARBURTON. It is concerned with 50 species and varieties of the genus. All the descriptions are original; they include three new species and three new varieties, aberrant forms and numerous hitherto undescribed stages of known species. The work is beautifully illustrated by black-and-white sketches, and by uncoloured and coloured plates. The value of this monograph has been already indicated in previous reviews, and all that is necessary to add now is that the present part maintains the high excellence of those that have gone before, and forms the standard work on the subject in the English language. A first bibliography was published in 1911, but as many papers have appeared dealing with ticks and their relation to disease since that date, a second had become necessary; this contains 462 titles, and should prove most useful to workers on the subject.

THE PLAGUE OF NOISE.

In a little book recently published Dr. DAN MCKENZIE has come forward as a prophet of the Silences, in a more practical sense than Carlyle.⁴ He is deeply impressed by the evils of noise, to which attention has frequently been called in the *BRITISH MEDICAL JOURNAL*, and he has written in the hope of abating a nuisance which may conceivably

⁴ *The City of Din, A Trudge against Noise*. By Dan McKenzie M.D. (Glasg.), Fellow of the Royal College of Surgeons, Edinburgh. London: Adlard and Son, Bartholomew Press. 1916.

grow into a danger to the higher development of human faculty. The world, like Prospero's isle, is full of noises, of which it certainly cannot be said that they give delight and hurt not. The din in which dwellers in large cities live would shatter the strongest nerves if a certain tolerance were not bred by habituation. Dr. McKenzie aptly defines noise as painful sound, and he gives a lucid and accurate description of its evil effects on the organ of hearing, and on the brain and the general system. We fear there is much truth in his pronouncement that as modern civilization progresses the noisier it tends to become, because the invention of machinery plays so large a part in the evolution of industrial enterprise. Dr. McKenzie has not so far been able to detect any signs indicative of damage to the ear itself from the noises of everyday life; but to an auditory apparatus made delicate by catarrh or other morbid condition the din of street traffic is distinctly harmful. He rightly holds the motor horn in special abhorrence, and he curses it with a wealth of invective that might satisfy even Sir Henry Morris. But, although we agree with him that the horn is greatly abused, we cannot admit that it is "quite unnecessary." It should, however, be used with something of the remorse and mitigation which Malvolio entreated Sir Toby Belch to apply to his voice, and its hootings might be tuned to a uniform standard of tone and pitch. As far back as in 1910 Mr. John Burns gave a sort of promise that this should be done, but, as far as we are aware, nothing more has been heard of the matter.

Another cause of suffering to sensitive persons is the railway whistle. At the annual meeting of the British Medical Association in Birmingham in 1890, Dr. Thomas Barr, of Glasgow, expressed the conviction that the ear was injuriously affected by the shrillness of these whistles, and a resolution was passed asking that something should be done to abate the evil. But the railway companies turned a conveniently deaf ear to the appeal. More recently Professor Vittorio Grassi of Pisa suggested that the sound of all whistles, bells, horns, and other instruments used for signalling purposes on railway lines and by all kinds of vehicles, works, and so forth, should be less loud and piercing; and that stringent regulations should be made by public authorities prohibiting or limiting unnecessary and untimely noises, especially those of high pitch, which are the most hurtful to the ear and brain. Dr. McKenzie condemns the railway whistle as wholeheartedly as he denounces the motor horn; "in these days of electric signalling," he says, "the locomotive whistle is nothing short of an anachronism." It is significant that the motorist now finds a groan more useful than a shriek.

Among the other noises contributing to the general din is the loud music which nowadays makes conversation in places of public resort impossible. Théophile Gautier described music as the most expensive of noises; had he lived at the present day he might have been tempted to say that it is also one of the most irritating to sensitive ears.

The very worst effects of noise are seen in the present war, in which

Bellona storms
With battering engines

with a violence she has never displayed before. Dr. McKenzie refers to the possibility of making guns silent, but he offers no solution of the problem. Indeed, we gather that for the present he is doubtful as to the expediency of mitigating the noises of war. Even if we discovered a way of saving our men from the effects of noise, it is not in the least likely that the Germans would dispense with the use of so potent an instrument of "frightfulness."

Dr. McKenzie hints at the possible development of a protective deafness in the men of the future; the result of which would be that their sensitive brains would be spared "the paralysing impacts upon them of the heavy blows of artificial sound." This is a somewhat dismal speculation, but we are encouraged by his admission that a good deal has been done in recent years in the way of abatement of the noise nuisance. Smooth road surfaces have deadened the crushing and jarring sounds of heavy traffic, and police regulations have reduced the volume and variety of street noises. The substitution of electricity and hydraulic power for steam has considerably lessened the deafening sounds of machinery. Much remains to be done, but Dr. McKenzie ends his homily on a strong note of hope of final victory

over noise; this will, he says, "come all the sooner if public opinion can be educated to regard noise as an evil to be condemned and reformed out of existence with all possible dispatch." His book, in which the lightness of the style makes the solid sense of the matter easy of digestion even to a casual reader, will be a powerful help in the furtherance of the cause which he has at heart.

TREATMENT OF TYPHOID FEVER BY DESSY'S VACCINE.

In his thesis on the treatment of enteric fever with the vaccine prepared by Dr. Silvio Dessy, Dr. MAGLIONE gives a brief account of previous work in this field.⁵ Dessy's vaccine was first used in 1903; it contains over forty strains of *Bacillus typhosus*, grown for forty-eight hours on alkaline agar, and emulsified in a small quantity of normal saline. The bacteria are precipitated from this by adding a small amount of agglutinating serum of high potency, from a patient with enteric fever, and keeping at 40° C. for twenty-four hours. The clear supernatant fluid is poured off, the agglutinated and precipitated bacteria are dried by rapid centrifugalization, and then suspended in physiological saline, weighed, and treated with an equal volume of 1 per cent. caustic soda solution to dissolve them while they are shaken for three hours. Treated thus the microbes swell up into a mucilaginous mass like white of egg. This mass is diluted with distilled water saturated with carbon dioxide, so that each cubic centimetre of it contains one milligram of the bacteria. For the most part the bodies of the bacteria have gone into solution in the vaccine thus prepared. This vaccine is sent out in bulbs containing 1 c.c.m.; before administration by subcutaneous or intravenous injection it is to be diluted with five volumes of normal saline. The dose for subcutaneous administration is not mentioned; for intravenous injection the first dose is one-fifth of a bulb, and later doses, given at intervals of twenty-four or forty-eight hours, may be increased by one-tenth of a c.c.m. of the undiluted vaccine. These intravenous injections are generally followed by a rigor fifteen or twenty minutes later, and subsequently by an enlargement of the spleen. Maglione states that the vaccine should not be employed in patients with intestinal haemorrhage or myocarditis, chronic alcoholism, or tuberculosis. He gives details of 131 patients with enteric fever treated in the Italian Hospital at Buenos Aires with Dessy's vaccine between 1913 and 1915. From one to eight injections were given in different cases, the average being about four. Eight of the patients died—a mortality of 6.1 per cent. In two-thirds of the cases the treatment lasted for from three to twelve days. A chart is given which shows in a striking way the tendency of this treatment to cut short the fever. Between 1905 and 1911 the classical methods of treatment were used in 1,050 cases of enteric, with 159 deaths (mortality 14.2 per cent.), and an average duration of thirty-one days. With Dessy's treatment the fever lasted as long as thirty days in only one instance, and averaged under a fortnight. Dr. Maglione strongly recommends the treatment of the disease by the intravenous injection of this vaccine, and notes that it generally causes the fever to end by crisis. Its employment does not exclude symptomatic treatment. Without doubt he makes out a good case for further trial of the vaccine.

NOTES ON BOOKS.

DR. ESPINE WARD'S *Beri-beri: Its Etiology, Symptoms, and Treatment*,⁶ represents the thesis he presented for the degree of M.D. of the Queen's University of Belfast. After a general survey of the disease, a detailed clinical account is given of 32 cases which occurred in the prisons at Freetown, Sierra Leone. This is followed by a synopsis of the cases. The very interesting fact is brought out that, of the prisoners who developed beri-beri in the gaols, all had been feeding on rice and rice alone, and not on the ordinary diet they were believed to be having, and to Dr. Ward is due the credit of having discovered this fact. The

⁵ *Tratamiento de la Fiebre Tifoidea por la Vacuna Dessy*. By Roberto Maglione. A Thesis for the M.D. Degree at the National University, Buenos Aires. Buenos Aires: "La Semana Medica," Imp. de Obras de E. Spinelli. 1915. (8. roy. 8vo, pp. 168.)

⁶ *Beri-beri: Its Etiology, Symptoms, and Treatment; with a Detailed Clinical Account of Thirty-two Cases occurring in Sierra Leone*. By Espine Ward, M.D., B.Ch. Belfast: Mayne, Boyd, and Son, Ltd., and Wm. Mullian and Son. 1915. (Demy 8vo, pp. 84.)

ordinary diet of the prisoners in those gaols is a full one, and it would certainly be difficult to see how beri-beri could break out when such a diet was being used. Careful observations, however, revealed the fact that an alteration had been introduced at the beri-beri prisoners' own request, these individuals having asked for rice alone. This fact may well explain many other outbreaks of this disease which have so far puzzled students of its epidemiology. The synopsis of the cases shows careful and accurate work, and the thesis well deserves the honour the university conferred upon it.

Professor A. G. WOODMAN's book on *Food Analysis*⁷ is the outcome of his experience as a teacher at the Massachusetts Institute of Technology. Certain typical foods are selected to illustrate the more important methods by which the special problems of analysis may be attacked; the book is therefore one for the student of analytical chemistry rather than for the practising chemist. Especial attention has been devoted to the chapters on the analysis of fats and oils, carbohydrates, and alcoholic beverages. The author writes with clearness and prolixity; he deals with many articles of food that are commoner in America than Great Britain. Naturally the text owes much to previous writers on the subject, and the author expresses a special debt of gratitude to the publications of the United States Bureau of Chemistry. Numerous references to the literature are given, and numerous statistical tables. The book appears to serve its purpose admirably, and may be recommended to the attention of those for whom it is designed.

A book on botany⁸ for students and teachers engaged in study for the Senior Cambridge Local Examinations in the upper forms of secondary schools has recently been written by Mr. THODAY. It assumes no previous knowledge of the subject, and is both lucidly written and well illustrated. It is meant to be used in conjunction with nature-study and work in the practical laboratory. The author clearly has had a considerable experience of the teaching of elementary botany, and his book may safely be placed in the hands of those for whom it has been designed.

MEDICINAL AND DIETETIC PREPARATIONS.

Esprit de Liège.

ALTHOUGH for many years much of the "Eau de Cologne" sold in this country has been manufactured here, and a formula for it under the name "Spiritus Coloniensis"—is given in the *British Pharmaceutical Codex*, the various brands actually made in Cologne continued to have a large sale before the war. The name "Eau de Cologne" has now ceased to be appropriate, and there appears also to be a strong objection on the part of many to naming a useful article for the toilet and sick-room after a German town. An excellent spirit of the same kind is now put forward under the name "Esprit de Liège," and a sample has recently been submitted to us by the manufacturers, the Peace Pillow Company (17, Manchester Avenue, London, E.C.); it is a perfume similar to that which it is intended to replace, but not identical with it, very sweet and refreshing, and leaving no trace of unpleasant residual odour when evaporated. It will be an excellent perfumed spirit for the sick-room, and will no doubt achieve popularity.

YELLOW FEVER.

A SERIES of reports on questions connected with the investigation of non-malarial fevers in West Africa, instituted by the Yellow Fever Commission¹ recently appointed by the Colonial Office, have been published as supplements of the Yellow Fever Bureau *Bulletin*. They form two bulky volumes, of which the first has 7 plates, 9 plans and maps, and 128 charts, the total number of pages being 352. Volume II has 12 plates, 1 map, 107 charts, and contains 400 pages. It is thus evident that an enormous mass of material has been collected, and Sir James Kingston Fowler in his preface states that "whilst accepting no responsibility for the views expressed in these reports, the Commission are of opinion that the results of these

researches, conducted, as many have been, in the face of very great difficulties, should be placed on record, not only to commemorate the painstaking efforts of the investigators concerned, but also because they may prove useful as a basis for criticism and discussion, and may thus assist in the solution of the problems which still confront those whose administrative duties bring them into contact with yellow fever."

The recent history of yellow fever in West Africa is interesting. The late Sir Rubert Boyce, it will be remembered, some years ago propounded the theory that yellow fever was universally endemic all over the West Coast of Africa. If he had said that it prevailed endemically in certain areas, probably no one would have seriously disagreed with him, but the assertion of its universality was severely criticized. In many ways, however, these present reports are a result of Boyce's views. They bring out the fact—a fact, however, not seriously disputed before—that epidemics of yellow fever do from time to time occur in West Africa, the origin of which cannot be traced to importation from other parts of the world. The disease can, then, be spoken of as being endemic in West Africa, or at least in parts of it.

Yet another point brought out is the difficulty of diagnosing yellow fever, not only clinically, but even in some instances pathologically after death. The parasite of yellow fever is still unknown; there is therefore no single definite test by which it can be established that any individual case is or is not one of yellow fever. Mild atypical cases are notoriously difficult of diagnosis, and as those who thus suffer do not die, it is not possible to be absolutely certain the attack was one of yellow fever. This is a point in connexion with which much work remains to be done. It is, of course, right to state that Seidelin, one of the Commissioners' investigators, claims that he has discovered the parasite of yellow fever, and the open-minded attitude the Commission takes is shown by the fact that papers for and against that view appear side by side in the second volume of these reports. The destructive criticism of Seidelin's views contained in a recent paper by Wenyon and Low finds support in papers by David Thomson and Lieutenant-Colonel Harvey, and it seems probable that the suggestion that the paraplasm is the parasite of yellow fever will not survive. In that case much of the matter in vol. II will have no permanent value, as, for instance, the chapters on experimental yellow fever in laboratory animals, reports on the transmission of *Paraplasm glaucigenum*, and the report on some histological lesions observed in laboratory animals infected with yellow fever. Apart from these criticisms, many of the other reports are very valuable, and show evidence of careful and painstaking work. Lieutenant-Colonel Statham's conclusions on page 386 should be carefully noted by future investigators of the disease in West Africa. The pendulum has swung to the other side, and, as he states, fever with transient albuminuria is now considered highly suspicious of yellow fever. Albuminuria, however, is common not only in some of the types of malaria, but also equally in many other conditions, so that too much stress must not be laid on the symptom. Dr. Wyler's and Dr. Leonard's reports give a good idea of the yellow fever cases observed in Lagos during 1913 and the beginning of 1914. No one who has seen yellow fever in the West Indies and South America can read these reports without being convinced of the correctness of the diagnosis. Some of the cases which showed malarial parasites in the blood—notably, for example, Case 26, p. 270—might be questioned, but about the majority there is not the slightest doubt. The only point lacking in the reports of the cases is the absence of careful blood counts per cubic millimetre and differentially. It is a pity that so good a chance was lost.

The volumes as a whole, then, form a valuable contribution to our knowledge of yellow fever, and they will no doubt give rise to criticism and discussion. One word of warning to those who administer the West Coast colonies—*Stegomyia fasciata*, the carrier of yellow fever, seems to be as prevalent as ever in many parts of the coast. Now is the time to act against it. To wait until another epidemic appears will be too late. To be forewarned is to be forearmed; remove the intermediary and there will be no further trouble with the disease it carries. The examples of Cuba, Panama, Colon, and Rio point the way.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on February 8th, twenty cases were considered, and £170 10s. voted to fifteen of the applicants. The following is a summary of the cases relieved:

Widow, aged 73, of M.D. Dubl. who practised in London and died in 1876. After her husband's death she settled in Brussels and took in paying guests, and did well and was able to save. At the outbreak of war her house and contents were taken over by the enemy, and all her savings were in Belgian stocks, which she cannot realize. Has been living with friends, but this cannot continue. Voted £9 in six monthly instalments.

Widow, aged 52, of M.R.C.S. Eng. who practised in Wolverton and died in 1912. Was left fairly well off, but brother-in-law, who had her affairs in hand, has disappeared and taken all with him. Has tried to earn a little by taking in boarders, but not successfully. One son, aged 17 years, who only earns 5s. a week. At present in great financial trouble. Voted £12.

Daughter, aged 72, of M.R.C.S. Eng. who practised in London and died in 1872. Applicant managed to earn a living as a governess until a few years ago, when she became totally deaf, and suffers with rheumatism. Only income a pension of £25 from the Governesses' Benevolent Institution. Voted £12 in twelve instalments.

Daughter, aged 32, of M.R.C.S. Eng. who practised at Wolverhampton and died in 1884. Applicant has had continuous bad health for years. Only able to work a few hours a day, and earns about 6s. per week by teaching typewriting and book-keeping. Relieved eight times, £58. Voted £12 in twelve instalments.

Widow, aged 35, of M.R.C.S. Eng. who practised at Swansea and Liverpool and died in 1914. Applicant is suffering from paralysis of the right side, and is quite unable to do anything. Has one child aged 7 years, whom the Guild are going to see if they can assist with respect to her education. Applicant lives with her mother, who is not well off. Relieved once, £12. Voted £12 in twelve instalments.

Daughter, aged 59, of M.R.C.S. Eng. who practised at Battle and died in 1873. Applicant suffers from chronic rheumatism and defective eyesight; she is quite unable to work, and is dependent on a sister. Relieved thirty-two times, £254. Voted £12 in twelve instalments.

Daughter, aged 59, of M.R.C.S. Eng. who practised at Box and died in 1894. Applicant lives with two sisters, and all have indifferent health. Receives a little help from friends and from another charity. Relieved eight times, £126. Voted £18 in twelve instalments.

Widow, aged 69, of M.R.C.S. Eng. who practised in London and died in 1893. Applicant's health is very bad, and she has recently had an accident which left her lame. Has a house which she lets, but cannot get the rent from the tenant, so is in temporary difficulties. Relieved once, £10. Voted £12 in twelve instalments.

Widow, aged 68, of M.D. St. Andrews who practised at Kidderminster and died in 1884. Before the war she managed fairly well by taking in lodgers, but lately has lost them all, as they have joined the army, and recently has been ill in bed. Relieved once, £10. Voted £12 in twelve instalments.

Daughter, aged 41, of M.R.C.S. Eng. who practised at Scarborough and died in 1879. Applicant makes a little by occasional nursing, but has not been successful of late. Relieved eleven times, £107. Voted £10 in two instalments.

Widow, aged 67, of M.D. Lond. who practised at Hoxton and died in 1897. Was left quite unprovided for at her husband's death, with one daughter, who worked as a milliner, but is now without a post. Makes a little by letting her house furnished in the summer, but not sufficient to enable her to manage. Relieved five times, £60. Voted £10 in two instalments.

Widow, aged 66, of M.R.C.S. Eng. who practised in various places and died in 1903. Applicant has two children, both married, and only able to help very little. She is too old to do anything herself in consequence of indifferent health. Relieved twelve times, £142. Voted £12 in twelve instalments.

Daughter, aged 54, of F.R.C.S. Eng. who practised in Bedfordshire and died in 1890. Applicant was left entirely unprovided for, and the state of her health prevents her from taking any permanent work. Relieved ten times, £76. Voted £12 in twelve instalments.

Widow, aged 58, of L.R.C.S. Edin. who practised at Fulham and died in 1910. Applicant endeavours to earn a living by taking boarders, but has not been very successful, and her health has been very indifferent of late. Relieved three times, £25. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

A SCHEME for the establishment of a school of dental surgery, to be closely allied to the medical school of Columbia University, is under consideration.

GERMAN PRISON CAMPS.

Much has been heard of the brutality with which the Germans treat the prisoners of war, especially the British, who have fallen into their hands. The evidence as to this in the early days of the war, when the enemy thought he was carrying all before him and could do as he liked, is overwhelming. Things have changed to a certain extent now that chastened hopes have dictated prudence. Moreover, though the lot of the prisoner can never be a happy one, there have all along been differences in the conditions in the various camps, due partly to the personality of the officers in charge, partly to the difficulty of accommodating and providing for masses of men suddenly brought together and kept under guard in places unsuited for the purpose. It may be interesting, therefore, to give the experiences of some medical prisoners. They may be compared with those of Mr. L. J. Austin, Dr. A. R. Elliott, and Captains C. T. Edmunds and E. S. B. Hamilton, and Lieutenant W. S. Danks, R.A.M.C., published in the JOURNAL of January 23rd, 1915, p. 165. Readers may also be reminded of the interesting account of an outbreak of typhus fever in a German prison camp given in the BRITISH MEDICAL JOURNAL of November 20th, 1915, p. 737, by Major P. C. T. Davy, R.A.M.C., and Captain A. J. Brown, R.A.M.C. (S.R.). They were captured on August 26th and 27th, 1914, and were kept in various prisons with other British officers, without being employed in their medical capacity, till February 11th, 1915, when they were sent to Gardelegen.

Dr. Etienne Breton, a French army medical officer, who was taken prisoner at Maubeuge, was first sent to an officers' camp at Gutersloh; some time afterwards at his own request he was transferred to a soldiers' camp at Münster in Westphalia.¹ There he found that for nearly 12,000 men, comprising about 400 English, 500 Belgians, a score of Russians, and more than 10,000 French, there were only four doctors—a Russian, a Belgian, and two German. Two days after Breton's arrival the Russian and the Belgian were sent away, and the Germans being of little use, he asked for assistance, and was assigned two French doctors who remained with him till they were all liberated in July, 1915. The German doctors were replaced by two others who were very devoted and kind to the prisoners. Breton makes graceful acknowledgement of the help he received from "the thoroughly well instructed infirmarians of the R.A.M.C.," one of whom, Sergeant Walter Tindall, was for eight months the greatly appreciated dentist of the whole camp. The sick who were able to get up were paraded every morning. Cases of fever were sent to hospital. The other cases seen were chiefly bronchitis and laryngitis, neuralgia, stomach and bowel troubles, rheumatic pains due to insufficient bedding (often consisting of wood shavings or straw), cachectic oedema without albumin, skin diseases caused by vermin, urticaria, pruritus, boils due to bad pork, ham, and sausages, and the pies of liver and lung which formed the staple of their diet. Herpes zoster was very common, and the men, especially the Russians, suffered much from severe chilblains. There was a good deal of neurasthenia, especially among prisoners from the occupied regions who never received either letters or parcels from their families. After a time Breton was able to procure for this class some additions to their diet, and he organized a fund which further helped them. Although at first only a few stock medicines were served out almost at haphazard, later the doctors could order "at their discretion" aspirin, antipyrin, pyramidon, quinine, morphine, tincture of opium, calomel, rhubarb, ipecacuanha, Karlsbad salts, and other drugs. For the parasites they had camphorated oil and a pomade with a basis of powdered sulphur and balsam of tolu (10 per cent.), which was very effective. For the dressing of wounds sublimate was freely supplied, oxygenated water and tincture of iodine more sparingly. Antiseptic gauze was readily got, cotton-wool not so easily. There was a service of massage and movement cures carried out by a British orderly, which gave excellent results. There were special blocks for tuberculosis, for fever, and for wounded men, each accommodating 25 to 30 patients. In these blocks the mattresses, instead of being on the ground, were on wooden bedsteads, and the wards were better lighted and ventilated; they were also

¹ *Paris médical*, December 11th, 1915.

heated. Every ten days a batch of twelve patients with incipient tuberculosis was sent to a sanatorium with 400 to 500 beds, where they were better nourished and had better conditions generally than in the camps. All the prisoners were vaccinated against small-pox, typhoid, and cholera. For typhoid Pfeiffer's vaccine was used. For cholera a serum having no special name was employed. The German doctors could give no account of its composition, effects, or results.

In the *Journal of the Royal Army Medical Corps* for November, 1915, Captain W. K. Beaman relates his experiences. He was taken prisoner with several other medical officers at Landrecies on August 26th, 1914. A few days later they were sent to Germany. At various places on the way they were insulted and threatened, and they were kept very short of food. "The German Red Cross give no food to prisoners, wounded or otherwise. At times it is shown to them and then withdrawn, with kindly remarks that 'it's not fit for swine.'" On September 4th the party reached Torgau, where they found some sixty British and hundreds of French officers. They were housed in soldiers' barrack-rooms. Each had a bed consisting of a straw mattress on boards supported on an iron frame. The bedding consisted of two blankets, one sheet, pillow-slip, and blanket-bag, which served the purpose of a second sheet. Food was bad, but extras, such as jam, ham, and sausage, could be bought at the canteen. The latrines were very dirty and were cleaned out only when absolutely necessary. There was a good system of shower-baths with hot and cold water, and a daily bath could be got. For exercise there was at first only a small yard, but later an outer court was opened where football, rounders, and tennis could be played. In November all British officers were transferred to Burg. Equal numbers of Russians and English were placed in each room, and no two British officers were allowed to sleep side by side. They were lodged in converted gunsheds and stores; some rooms were fairly good, others very bad. Discipline was strict and oppressive. All the German officers were very hostile to the British, but much less so to the Russians and the few French who were there. The latrines were deep trenches, very dirty, and quite insufficient. Only one bath a week was allowed. The food was generally eatable, but the quantity was insufficient.

On December 6th Captain Beaman with thirty-six others left Burg for Halle. In the old factory in which they were placed dirt was the prevailing feature and lice were fairly plentiful. British, French, Belgian, and Russian officers were all lodged in large, ill-ventilated dormitories. The latrine was a deep trench, very dirty, insufficient, and cleaned out only as a last resource. The food was cheap but very bad. Some extras such as sausage, ham, jam, and margarine, could be bought at the canteen. A daily bath could be had. Discipline was not so strict as at Burg, and the German officers were quite agreeable and polite. During December and part of January, 1915, all foodstuffs were taken from the prisoners' parcels for the Red Cross, which gave no receipts. In February Captain Beaman was transferred to Quedlinburg, a soldiers' camp, where he was nominally in charge of the English prisoners. There were fourteen other medical officers—twelve French and two Russians, who were housed in small wooden huts. The 10,000 prisoners in the camp—Russian, French, and British—were housed in wooden huts which were not rain-proof. Two blankets a man and mattresses stuffed with shavings, four for six men, were issued. Food was scanty and unappetizing, at times uneatable. Without parcels from home the men would almost have starved. The feeding improved somewhat when the administration took over the messing from contractors. Medical arrangements were satisfactory. There were ample dressings, but occasionally a shortage of drugs. The old hospital left much to be desired, but the new one was good. An isolation hospital was ready in case of an epidemic. The general health of the camp was fairly good, though tuberculosis in every form was rife; pneumonia and bronchitis were common. All this was due to overcrowding and deficient food. No isolation of tuberculous patients was carried out. Practically no clothing was provided by the German administration, and it was very difficult to obtain clothes sent out from home for the British prisoners. Captain Beaman says that the British owe a great debt of gratitude

to the American Ambassador at Berlin, who, in the face of much obstruction and subterfuge, had done much to relieve the sufferings of the prisoners. "Much yet remains to be done, and it must always be remembered that an inspection of a camp is a set piece, much forethought being expended by the authorities as to the staging."

Dr. François Léonetti paints a darker picture of his captivity.² Taken prisoner at the battle of Macquigny (Aisne) on August 29th, 1914, he had a narrow escape from the revolver of a German officer, who said the inhabitants of a village occupied by the victorious troops had poisoned the wells. His life was saved by the intervention of a German doctor. After working in the Hôtel-Dieu at Guise till January, 1915, he was sent to Gastrow in Mecklenburg, a camp where there were 12,000 Russian, 4,000 French, 2,000 Belgians, and 1,000 British prisoners. All were in tents without sufficient protection from cold and wet, and were suffering from hunger and infested by vermin. The French soldiers had been allowed to keep their kit, but the Russians had been compelled to exchange their boots for bad wooden shoes, and cloaks and body linen had been taken from the British. The sanitary conditions were of the very worst kind and lice swarmed on clothes, blankets, and mattresses. No precautions were taken against disease. Accommodation for the sick was very inadequate, and the doctors had only morphine, aspirin, and tincture of iodine at their disposal. Typhus fever raged in the camp for five months. There were hundreds of wounded, who could not be treated owing to the want of dressings. Everything was lacking—linen, bedding, drugs, and suitable nourishment. The medical service at first consisted of two German students, but a few days after Léonetti's arrival there were seven French doctors, and some weeks later four others, two French and two British, were sent. Gradually things improved, and in March the only serious ground of complaint was the insufficient food. At that time parcels began to arrive more regularly from France and England, and the contents were distributed with admirable comradeship. The British, who had been more exposed to the cold as their clothes had been taken from them, suffered a good deal from nephritis, which, however, was of mild type. All the prisoners suffered much from frostbite. Antityphoid inoculation with Pfeiffer's serum was carried out, and as the men were vaccinated they were sent away to other places and put to agricultural or factory work. Léonetti estimates that 60,000 men passed through the hands of the doctors. He gives an amusing account of the care with which the camp was prepared for a visit from the Spanish Ambassador. His Excellency was taken round and invited to admire the cleanliness of the huts, the arrangements for disinfection, and so forth. The only thing that had been forgotten was to show samples of the food. One of the prisoners boldly placed himself before the ambassador, showed him the uneatable bread, and told him of the insufficiency of the diet. The German colonel said the bread had been tampered with. Red Cross visits and official inspections all had the same result. The Germans are, says Léonetti, past masters in this kind of stage management. At the beginning of April he was sent to Langensalza, a watering place in Thuringia, where an epidemic of typhus had been raging in the camp since January. Of fifteen doctors who had gone there in March, nine were already attacked. There was scarcely any accommodation for the patients, who in one week numbered 3,000, with only five doctors to attend them. There were no medicines. Men sickening with the disease lay on the floor in corridors during the day, and were sent back at night to their quarters where they mixed with their still healthy comrades. There was at first no attempt at disinfection, and the German doctors refused to admit to hospital cases of typhus in which there was no well-defined eruption. Even after stoves were set up, clothing was given back at haphazard and so imperfectly treated that it served as a means of distributing vermin. The German doctors never dared to go near the patients, and French doctors had to be appealed to. A specialist, Dr. Rheberg, was sent from Berlin, to whose courage and devotion a warm tribute is paid. The epidemic wore itself out after nearly 95 per cent. of the prisoners had been attacked; probably some mild cases

² Souvenirs de captivité, Thèse de Paris, 1915.

escaped observation. In the early part of May Léonetti was sent with six other doctors to Niederzwehren near Cassel in Westphalia, where an epidemic of typhus had been raging since February, but the deaths were put down to influenza, gastric troubles, and bronchitis. The authorities were indifferent, the general in command saying frankly that he was making war in his own way, and that a dead prisoner meant one ration less. When, however, the epidemic at the end of March spread to the German Guards, to the garrison of Cassel, and finally to the town, the gravity of the situation was recognized. Foreign doctors were sent for and by the end of June there were eighty-eight in the camp. The conditions were very bad. There was no hygienic installation, the stench was dreadful, nationalities were mixed up, and there was the usual want of food. Under the pretence of disinfection the wretched mattresses and blankets were taken away and the men had to lie on bare boards. On Léonetti's arrival there were 6,000 sick. He admits that praiseworthy efforts were then being made to supply appropriate shelter and drugs and milk in sufficient quantity. Isolation was provided, disinfecting stoves were set up, and means were adopted for destroying vermin. But as the result of what he calls the criminal carelessness shown at the outset there were up to July 14th 1,700 deaths among French, British, and Belgian prisoners, and 900 among the Russians, a total of 2,600. Not all these deaths, however, were due to typhus. Léonetti, who returned to France in July, says that few camps escaped typhus. At Erfurt, where the epidemic was promptly suppressed, there were only 600 cases in a population of 20,000. At Cassel and Langensalza thirty doctors were attacked by the epidemic, of whom nine died. Léonetti says that but for the Allied doctors the state of the prisoners in Germany would have been more deplorable. Thanks to the unceasing efforts of the committee of the Red Cross, improvements on certain points were made, but much still remained to be done.

There is a mass of corroborative evidence from various quarters as to the unhappy condition of prisoners of war in German camps, but we have chosen to limit our selection to medical witnesses. It is only fair to state that correspondence between our Foreign Office and Mr. Gerard, the United States Ambassador at Berlin, shows that there has been a great improvement in certain camps since May, 1915. Writing of Ruhleben on November 1st, Mr. Gerard says that a satisfactory system of drainage was completed in September, and more washhouses had been provided. Notwithstanding his repeated protests, however, the camp lazare had never been satisfactory, though decided efforts had been made during October to improve it, including the provision of hot and cold baths. He submits figures of winter clothing supplied, including overcoats and underclothing, showing that about 60 per cent. of the camp have been so accommodated, and also other statistics tending to prove that the canteens have been ably and economically administered. Mr. Gerard states that when he visited Ingoldstadt in Bavaria on January 15th, there were some 4,000 prisoners, among them 11 British, in the camp. Food was about the same as that often described. The midday meal on the day of his visit consisted of tripe and potatoes. The cooking was done by Frenchmen. The British all had sufficient clothes and two blankets each. Baths (hot and cold shower) were allowed practically whenever desired, and the men were allowed to get hot water for washing clothes from the bath-house or kitchen. The British prisoners had no particular complaints. The barrack where they slept was rather crowded, the double-deck system being in use. The barrack floors were dirt only, or rather mud, with a board strip. The commandant promised to see that the roofs, which leaked in places, were repaired. The British prisoners worked on the railway, etc., and also in the large military hospital. They stated they preferred work of this kind to doing nothing. They were allowed to play football. There was a camp library and a theatre where weekly performances were given. The relations between the camp officers and the prisoners seemed excellent. There was a well furnished canteen where reasonable prices were charged. The men received letters and parcels promptly, but were charged 5 pennings for each parcel. This charge was made, the commandant told Mr. Gerard, to create a fund for the prisoners who received neither gifts nor money.

We have had the opportunity of seeing a report by the Hon. Ella Scariett-Synge, M.D., of a visit she was allowed to make to camps at Wittenberg, Giessen, Göttingen, and Ruhleben. She formed the opinion that the sanitary and other conditions in these places was satisfactory. Complaints were few, and the prisoners were contented with their lot, except the English, who sometimes found fault—unreasonably, it is suggested—with the food; they grumbled at the state in which their parcels reached them—this, again, is said to be due to faulty packing—and, unlike other nationalities, would not work even for pay. Theatrical performances, musical performances, and other entertainments were given, and opportunities of education in languages, art, and other subjects were offered. With all these advantages, accompanied by every care for the needs of the body and also of the soul, it would seem to be a piece of good fortune for a young man to be a prisoner in Germany. But some doubt assails us that the picture is a trifle too rosy. We do not suggest that the lady is a victim of that antinational bias which is so curious a feature in the mentality of a certain section of our people. We are rather inclined to believe that she has been, at least in some degree, misled by the German skill in stage management, of which the other medical witnesses speak. She proposes that an English commission should be sent to Germany to report on all camps, while a corresponding German commission could come to this country with the same object. Frankly, we do not think the British public is prepared to accept the report of a commission of representatives of a people who meet charges of atrocities testified to by countless witnesses, and accepted as fully proved by British, French, and Belgian commissions of the greatest weight, by belated denial.

Typhus fever is a sure index of sanitary inefficiency and underfeeding, and the fact that outbreaks of the disease have occurred in most if not all German prison camps is not denied. Quite probably the sufferings of the prisoners are in many instances rather due to the breakdown of the German organization than to deliberate malice, and as has been said there is evidence that efforts are being made, in some camps at least, to improve matters. Reports by members of the staff of the American Embassy at Berlin, published early in March, indicate that conditions at the prisoners of war camps at Limburg, Giessen, Darmstadt, Mannheim, and Heidelberg are now satisfactory. The camp at Mannheim, where there are sixty British prisoners, is described as a "good example of the specially and scientifically constructed camps, and general conditions are of the best." Much of this improvement is due to the courage and persistency of the American Embassy, and, according to Mr. Ian Malcolm, there is now hope that even the Russian prisoners who have suffered so severely from typhus will be treated with more consideration. In a letter published in the *Times* a short time ago he stated that the Swedish Red Cross Society had called a conference in Stockholm last December of representatives of Russia, Germany, Austria, and Hungary. The delegates adopted unanimously a series of recommendations, which, it is hoped, the respective Governments will accept. The gross mismanagement of the prison camps in Germany during at least the first year of war will always remain as evidence of the inefficiency of German sanitary administration, and, we regret to add, a blot upon the competence and courage of the medical profession of that country.

PROFESSOR BEREZNEGOWSKY (*Wratsebnia Gazetta*, No. 22-23) relates some cases of gunshot wounds observed by him, which, in his opinion, could not be caused by any other but explosive bullets. The presence of a great number of loose fragments and particles of bones and metals, as seen by the x rays, the extension of the laceration to the soft parts, and the black edge around fresh wounds, all afforded evidence that the latter were not caused by an ordinary massive bullet producing a "humane wound," but by one which explodes within the body into a number of small fragments. If the claims of the officers are true, that some bullets explode while in the air, there ought to be cases in which small multiple fragments are found in the body without tracing any entrance or exit wound. Such a case has been observed by the author, in which the clinical picture corresponded with the history related by the injured. The observations made by the author were in the districts of the north-west front from Bzura to Mitawa at different times.

British Medical Journal.

SATURDAY, MARCH 18TH, 1916.

ENROLMENT: AN URGENT NATIONAL NEED.

THE Central Medical War Committee is organizing meetings at four centres in England and Wales, to be held in the course of next week. The centres chosen as likely to be most convenient to the largest number are Leeds (March 21st), London (March 22nd), Birmingham (March 23rd), and Bristol (March 24th). The purpose of the meetings is to ensure the success of the enrolment scheme, and two members from each local Medical War Committee will be invited to attend. It is essential that, in the interests of all, every medical man of military age throughout the country, whether fit or unfit; whether employed by a public authority or in private practice in any capacity whatever; whether he can be spared from the district in which he practises or not; whether his personal difficulties are great or small, should enrol—that is to say, should sign the form of application for a commission, whereby he expresses his willingness to serve his country if at any time in the future the need for his services should arise. His application will be retained by the Central Committee, and when the enrolment of every man is complete the selection of those who can most easily be spared to take commissions in the R.A.M.C. can be carried out with absolute fairness to the profession and to the community. Not all, probably not half, the men who have signed the enrolment form will be required for service; but, under the enrolment scheme, no man will be placed in the difficult position of deciding for himself when it is his duty to go.

It has been urged by many critics of the work of the Central Medical War Committee that the supply of medical men to the army has been ample; that occasional local shortages are due merely to bad organization, or to lack of regard to the economical use of officers already commissioned; and that further depletion of doctors in civil life may lead to serious danger to the community. To these arguments we reply that however ample the supply may have been in the past, wastage is always considerable and is certain to increase. How can it be otherwise when the country has armies in the field not only in northern France but in the Mediterranean and in Mesopotamia, where the troops have to encounter risks of tropical and subtropical diseases? We reply also that, under the present organization of the medical department, the number of medical officers employed is less than the recognized normal establishment for armies of the present size; that organization may be defective, but it has achieved remarkable success in Flanders and France, is constantly being improved as experience increases, and cannot be changed fundamentally at a moment's notice; that economies are already being effected and will increase as time goes on; and, finally, that no shortage of doctors in civil practice is visible at present comparable in the slightest degree to what appears to be the case with some of our armies abroad.

To those who still doubt the necessity for the

enrolment scheme of the Central Medical War Committee we recommend perusal of the report at p. 427 of the remarks made by several members, during the discussion in the House of Commons of the Army Estimates, with reference to the defects which persistent rumours assert have marked the arrangements for the treatment of the wounded in Mesopotamia. The extract Mr. Lambert read from a letter of a wounded officer as to the lot of the wounded during evacuation from the field to the base at Basra is disquieting, and the statement that two hundred wounded spent five or six days on a paddle steamer in the Tigris, "lying anyhow on the deck with only one medical officer and practically no medical equipment," is evidence of shortage. Mr. Long, who replied for the Government, admitted that the medical arrangements had been inadequate, that the Government of India had instituted a special inquiry on the spot, and that the War Office had found it necessary to send two Indian general hospitals complete, and the personnel of two more, a British stationary hospital of 400 beds, and a British general hospital of 1,040 beds, as well as during the last month 100 doctors to Mesopotamia. It is alleged in many letters received in this country that the scarcity of doctors in Mesopotamia is deplorable. We know that the Indian Medical Service has already lost heavily, and it seems certain that the War Office will require many more medical officers for Mesopotamia in addition to those who have already left, or are about to leave, this country. Supposing that the whole of the accusations of defective organization and lack of economy were true, do the critics suggest that this is a reason why "seriously wounded officers and men" should be "left for two or three days with no further attention to their injuries than the first field dressing"? Are lives to be lost while members of the medical profession are making up their minds whether their duty is here or abroad with the army? Is it right that Government departments and individuals should be trying to see how much of their medical services they can preserve to the civilian community rather than using the whole of their energies to see how much they can spare? Troubles such as are alleged to be occurring in Mesopotamia may happen at other points in the area of war. No man knows where the next difficulty may arise, or in what part of the globe it will be necessary to employ our military forces.

Without organization it is impossible for the medical profession to meet the call for officers. An integral part of that organization is that the national medical war committees of these islands shall be in a position to know exactly how many men are available and how they can be spared with the least disturbance of the interests of themselves and of the people at home. The letter from the chairman of the Barnet Local Medical War Committee shows the spirit in which the enrolment scheme should be accepted and how difficulties can be overcome by co-operation among the medical men of a district who are loyal to their country and each other. The haphazard methods of recruitment by individual offers can no longer be relied on; the men from whom further recruits must be drawn are the men whose difficulties are hard to overcome. To such men, who are at heart as anxious as others to serve their country in every way possible, the Central Medical War Committee, the Scottish Medical Service Emergency Committee, and the Irish Medical War Committee offer the only sound and fair method of meeting the exigencies of their position. And that method is Enrolment.

"SIGHT" FOR THE BLIND.

IN the columns of a well-known London daily there has appeared within the last few days an article of considerable length giving a rather elaborate account of certain experiments which seemed to promise the production of an apparatus of use as a "substitute for sight." Every one knows that the sun may be felt as well as seen, and probably not a few school-boys have experienced the torment of being subjected to the effects of the focussing of a "burning-glass" upon their skins. Yet this is made the basis of a lengthy disquisition on a substitute for sight. It is proposed with every appearance of seriousness that a burning-glass should be placed in such a relation to the breast of the blind subject that the light focussed by the lens should fall accurately upon the skin; means would be taken by the interposition of screens to prevent burning, and by a process of training the subject would learn to see by means of the feel of the warm picture on his chest. The educational process would be carried out by placing a series of stencils on the chest which would leave slits, circles, and later on letters and signs exposed to the heat rays, and the sense of heat perception would be increased by its cultivation. All this sounds very much like the yarn that a schoolboy might write a very long way after Jules Verne, and one would have thought that a newspaper of importance would have secured the criticism of some physiologist before publishing such a rigmarole. But we notice that the article is under the heading "From German Sources," and the intention of the publication may be playful rather than serious. The excerpt begins "An article on optics of more than merely technical interest appears in the *Deutsche optische Wochenschrift*, and is quoted at considerable length by the *Tägliche Rundschau*. The writer is Professor L. Zehender, the Berlin eye specialist, who records an experiment which appears to have given rise to considerable discussion in German scientific circles." If this be a fair sample of the much vaunted *Ersatz*, the German palate that is satiated by new substitution products must be truly in a bad way.

The publication in a popular newspaper of this so-called "substitute for sight" may not do any particular harm, because, as has been said, it is so crude that the youngest would be able to understand how much and how little advantage the blind may expect to draw from it. Nor perhaps did any great harm come from the wide publication a few years ago of a plan for transmuting sight into sound out of which the blind were bidden to hope that they were one day to hear what others saw. It was based on a well-known scientific fact, but its practical application on even the simplest scale for the benefit of the blind presented insuperable difficulties, and even its promoters did not pretend that anything would come of it at present. So here again, for another reason, no great harm was done.

But it is otherwise with some of the schemes which from time to time are published in newspapers without any attempt at criticism. We are quite sure that the directors of these newspapers do not realize the effect such statements produce upon the blind themselves and upon the parents of blind children. Some of the schemes are dangerous to the man or the child who it is feared is going blind, and others make a cruel call upon the slender purses of the blind. The poor blind are very open to exploitation. Wonder healers and the like suck them dry of their poor earnings. Such an one as these had his "cures" vaunted in a newspaper not many months ago, but the child he "cured" is still blind and in a

blind school; yet he has been allowed to trumpet abroad an offer of his services for the cure of soldiers blinded in the war. A few years ago a healer fleeced a maidservant of nearly fifteen pounds on the promise to grow her a new eye to fill the place of one she had lost; either he was less cunning than most of his kind or the girl more resolute than ordinary; by exception he got his deserts in a term of imprisonment. In the last few months we have known of two cases of children whose parents, refusing the care of the hospital physician, have resorted to quacks, with the result that these two children are now blind from the grossest effects of interstitial keratitis.

There is another evil, and that is the publication of garbled versions of genuine forms of medical treatment and operation. Recently an unfortunate man, whose sight was nearly lost from progressive disease, came from the other side of the world in search of a cure that he had heard of through an American newspaper. He brought with him a scrap of paper that he handled like a talisman of hope. It was a typical American "wonder paragraph," and the effect of its words, which he knew by heart, was too strong to allow him to depart as he came. He could not be brought to believe that the cure would be for him a danger. He must needs put his hope to the test. When seen again, as he was about to return to his distant home, he had lost his hope and had exchanged the remnant of his sight for two blind and painful eyes!

The Select Committee on Patent Medicines in its report expressed the conviction that "the proprietors of the better class of newspapers . . . would welcome a drastic suppression of suggestive or improper advertisements," but went on to say that this observation did not refer "to the advertisements of swindlers like Macaura, the 'eye quacks,' the 'deaf quacks,' the cancer-curers, the consumption-curers, the electric belt makers, the curers of rupture without operation, or 'fakirs' generally. As regards these classes, most newspaper proprietors do not regard it as incumbent upon them to test the good faith of secret remedy advertisers, any more than of advertisers of other goods, though a few of the leading papers exercise a very severe censorship upon advertisements of this kind also." If the need for such censorship is felt in regard to advertisements the need must be even greater in regard to the publication of editorial articles, for all but the most hopelessly unwary know that the statements in advertisements must commonly be taken with a grain of salt.

We may well ask the lay press to "Pity the poor blind."

SCHOOL BOOKS AND EYESIGHT.

A FURTHER report of the committee of the British Association for the Advancement of Science has been issued¹ giving an account of the investigations of the committee with the intent to obtain an objective measurement of the gloss of paper. Hitherto we have had to be content with a purely subjective test, and such a method had to be varied with each individual; a highly sensitive subject found the reflection of a very little gloss on the paper prevented comfortable reading and was trying to the eyes, while another of more lymphatic temperament found a gloss tolerable that would have driven the other crazy. The committee report that glossiness of paper depends mainly on specular reflection—that is, reflection as from polished metals; such reflection is apt to interfere with binocular vision. The ideal surface for books would

¹ London: British Association for the Advancement of Science 1915. (Price 3s.)

exhibit no specular reflection; all the reflected light would be scattered or diffuse reflection, equal in all directions and independent of the direction of the incident beam. In practice it is found that when the specular reflection does not exceed the diffuse reflection when the light is incident at 45 degrees, the paper is satisfactory; when the specular reaches 56 per cent. and the diffuse only 44 per cent., then there will be injurious glare, especially by artificial light. The apparatus devised by Mr. A. P. Trotter, one of the members of the committee, for the measurement of these qualities is ingenious in its simplicity. It is a clever adaptation of the principle underlying the photometer and the Wheatstone's bridge. A box about the size of an ordinary microscope case has a slot in the lid along which an electric lamp within the box can be slid. Just below the lamp is a screen which prevents the direct light of the lamp reaching the bottom of the box; at each end of the screen is a mirror set so as to reflect the light round the screen and illuminate one half of a hole cut in the bottom of the box. The paper to be tested is put beneath this hole. At the ends of the box, just clear of the mirrors, are two peep-holes fitted with double prisms; through these the hole in the bottom and the paper to be tested can be viewed. By shifting the lamp from end to end a balance of the specular and diffuse reflection from the paper can be obtained, and the relation read off by the position of the lamp in the slot. The reading from one peep-hole can be checked by that from the other; both should agree in their proportions. It would be of interest if the committee would put a series of papers to the test and issue a table of results. The earlier reports of this committee, which dealt particularly with the print of school books, are exerting their effects upon printers and publishers. The Cambridge University Press have recently issued a new *Textbook of Arithmetic*,² by the Head Master and Assistant Master of the Royal Naval College, Osborne. The publishers call attention to the large type used for this book, which conforms to the standards laid down in the typographical scale of the British Association report. They have further graded the type of the different parts of the book, using larger type for the earlier chapters which will be used by younger children than is necessary for the more advanced chapters for the use of the higher classes. There is, however, one defect in the get-up of the book: the paper is scarcely opaque enough to prevent the print of the reverse side of the page and also of the contiguous page from showing through to the page in use. This reduces the necessary contrast of print and paper, and renders the good type less legible. Also the surface of the paper is such that it will readily get dirty in the usage. We may commend the publishers for their attention to the typographical scale of the British Association, but the same report dealt with the density and surface of the paper. It is scarcely within our sphere to criticize the matter of a book on arithmetic, but we may call attention to a serious practical defect. A chapter is devoted to the subject of stocks and shares; it consists of two pages of explanation, two of examples, and two of set questions. The whole is inadequate, and if it be considered worth while to include a chapter on such a subject in a school-book—and we have no doubt it is—then it should be reasonably adequate. Maybe the inadequacy of this chapter is an indication of the general want of knowledge of professional classes on such matters, an ignorance which is to their serious disadvantage.

THE ADMINISTRATION OF ANAESTHETICS BY UNQUALIFIED PERSONS.

SOME undesirable procedures may be condoned by the exigencies of a great war; proof of the necessity must, however, be adduced before the profession can admit that the giving of anaesthetics should ever be committed to

unqualified persons. We have seen a report of a matron being entrusted with this duty at a hospital when routine operations were being performed. No experienced person will deny that giving an anaesthetic involves grave responsibility, and patients may well expect that all professional work which involves grave risk will be carried out by registered medical practitioners. Even in the hands of the best trained anaesthetist patients die from or under an anaesthetic. Initial signs of complications are commonly very slight and can be gauged only by an experienced person, who, recognizing them, adopts remedial measures promptly. It is simple enough to train a nurse to pursue a routine method of anaesthetizing, and she, after a thousand or two administrations, will have mastered the technique, while incidentally she will believe she knows all about anaesthetics. But a professional man is aware that mastery of the technique is the least part of the outfit of a competent anaesthetist. He realizes that although comparatively few operations *per se* involve a risk to life, yet every time an anaesthetic is given life may be endangered. The uncontrollable factor—the patient—cannot be allowed for by a nurse, since even the accumulated science of the medical man may often be at fault. Is it, then, justifiable to permit a nurse or matron to give anaesthetics except in a sudden emergency? It is often urged that an experienced nurse can carry out instructions and give anaesthetics as well as a medical man, but if this contention is true for anaesthetics it may be held to be true also in other branches of medicine and surgery, and in pharmacy. In this way the door will be opened to every kind of unqualified practice. Since the induction of anaesthesia has now become a science as well as an art, ought a surgeon to salve his conscience by the excuse that although he permits a nurse to give his anaesthetics he keeps a watchful eye on her procedures? No man can do two things properly at one and the same time.

DEATH FROM PARATYPHOID FEVER.

FATAL cases of paratyphoid fever are sufficiently uncommon to be worthy of record. Seventeen such cases have been studied at a stationary hospital across the Channel, and the results have recently been recorded by Sir Bertrand Dawson and Dr. T. H. Whittington.¹ They remark that the clinical picture in these severe cases conforms very closely with that of typhoid fever, so that the diagnosis must be based on the laboratory findings. In thirteen instances rose spots were present; abdominal distension and the toxic "typhoid state," so-called, were often absent in these severe cases of paratyphoid fever. In four out of the seventeen patients the respiratory manifestations were prominent features; bronchopneumonia was present in two of these, lobar pneumonia at both bases in the third, and massive pneumonia with cavity formation from necrosis in the fourth. It has been shown that lobar pneumonia can be caused by typhoid and paratyphoid bacilli alone, although probably the pneumococcus is more often associated with them. So far as the circulatory system is concerned, the authors observe that a pulse slow in proportion to the temperature is one of the most characteristic features of paratyphoid, usually lying between 70 and 90. In severe cases, however, the pulse is rapid, and there is no other single sign so significant and prophetic, so long as the temperature is above 100° F. The blood pressure varies and is generally lowered, while the apex beat is difficult to palpate, a feature in keeping with the pale and flabby condition of the cardiac muscle sometimes found; endocarditis was not recorded once. The spleen was found enlarged *post mortem* in eight of the patients; in one it was but half the normal size, and in two it contained abscesses the size of hen's or pigeon's eggs. The small intestine was ulcerated in both the cases of paratyphoid A and in twelve out of fourteen cases of paratyphoid B; the large intestine was involved much

² *Arithmetic*. By J. Godfrey, M.V.O., M.A., and E. A. Price, B.A. Cambridge: The University Press, 1915. (Post 8vo. pp. 480. 4s. net.)

¹ *Quarterly Journ. Med.*, Oxford, 1916, ix, 98.

more severely than is usual in typhoid fever, the lymphoid nodules and Peyer's patches being inflamed or ulcerated from the caecum to the pelvic colon in ten of the instances of paratyphoid B. The appendix was a focus of mischief causing peritonitis in three patients, one a case of paratyphoid A; in two it was perforated, in the third intensely inflamed. There were five cases of peritonitis in the series; laparotomy was performed in four instances, two with perforation of the appendix, two with perforation of the intestine. None of these patients recovered, although, as the authors point out, the cases were constantly under the eyes of skilled observers and received the most competent surgical attention. It is pointed out that it is the internal conditions that are so unfavourable here; for one ulcer that has perforated there may be several more that have nearly perforated, and the patient's reactive power, both local and general, is down to vanishing point. Two of the patients died from intestinal haemorrhage, three from haemorrhage and toxæmia; the seventeen deaths represent a death-rate of rather over 4 per cent. in paratyphoid B, and under 1 per cent. for paratyphoid A. The authors conclude that there seems to be a tendency to pus formation in these cases; abscesses occurred twice each in connexion with the spleen, appendix, and lung, and once in the liver, while one of the pulmonary abscesses gave rise to empyema.

SIR GILBERT BLANE.

SOME time ago Dr. H. D. Rolleston, who is now a surgeon-general, R.N. (temporary), contributed to the *Journal of the Royal Naval Medical Service*¹ an account of James Lind, to whom beyond any one else we owe the abolition of scurvy among sailors. He has followed this up with a sketch of the career of Sir Gilbert Blane, who was born in Ayrshire in 1749, studied at Edinburgh, and graduated M.D. at Glasgow in 1778. He became personal medical attendant to Lord Holderness, a favourite at Court, and in this way was brought acquainted with Sir George Rodney, whom he accompanied in H.M.S. *Sandwich*, the flagship of the fleet sent at the end of 1779 to raise the siege of Gibraltar. Blane had no official position; nevertheless, during several engagements he was employed by the Admiral, in the absence of executive officers, to carry orders to the guns, and was slightly wounded. This led to his official appointment as physician to the fleet. On his return to England in 1781 he submitted to the Board of Admiralty a memorial pointing out the neglect of cleanliness, ventilation, and dryness in the ships, the need for a supply of lemon-juice to prevent and cure scurvy, the prevalence of intemperance, the inadequate provision for the care of the sick on board ship, the absence of proper bedding, the want of soap, and the desirability of a gratuitous supply to naval surgeons of medicines and other necessities. Nothing, however, was done at the time. At the beginning of 1782 he again went to sea with Rodney, and from these experiences afloat he gathered the knowledge of naval medicine and hygiene which he embodied in his *Observations on the Diseases of Seamen* (1788). On his return to London in 1783 he was elected physician to St. Thomas's Hospital, an appointment which he held for twelve years. He had considerable success as a physician, but his reputation rests mainly on his work as a reformer of naval hygiene. From 1795 to 1802 he was a Commissioner of the Board of the Sick and Wounded Sailors, a position which gave him the opportunity and the power to enforce the reforms he had previously advocated. An Admiralty Order enjoining the use of lime-juice in the navy, which came into force in 1796, banished scurvy from the service. In the same year he induced the Admiralty to provide soap for the crews. In 1802, in association with Count Rumford, he recommended ventilation of the lower decks of convict ships by means of wind sails and air tubes, with the result

that the incidence of infectious disease was diminished. Blane's demand that medicines should be supplied free to naval surgeons was conceded in 1804. About this time, too, the sick bay was transferred from the ill-ventilated forepart of the lower gun-deck to a position under the forecabin. These various reforms were followed by a remarkable improvement in the health of the navy. Whereas in 1782, out of 100,000 seamen and marines, the proportion admitted to hospital for sickness was 1 in 3.3; in 1813, with a complement of 140,000, the proportion of sick fell to 1 in 10.75. In 1809 Blane was sent to inquire into the prevalence of malaria and other diseases, which incapacitated more than two-thirds of our army in the unfortunate Walcheren expedition; his report led to the abandonment of the island. In 1825, in a letter to the directors of the East India Company, he expressed the conviction that cholera was spread by human intercourse, not by aerial influence, and a year before the great epidemic of 1832 he issued *A Warning and Admonition to the British Public on the Subject of Indian Cholera*, which was circulated in the seaports. His most important contributions to therapeutics were on the uses of pure alkalis and lime water in disorders of the bladder, stomach, and skin, and on the effects of large doses of potassium carbonate in gravel. Blane was ever zealous in his efforts to improve the professional attainments and position of naval surgeons; as a means to that end he founded the two gold medals which bear his name. Many honours came to him. He was a Fellow of the Royal Societies of London, Edinburgh, and Göttingen, and a corresponding member of the Imperial Academy of St. Petersburg and of the Institute of France. He was made a baronet in 1812. He held a number of Court appointments, among them that of physician to George IV and to William IV. Blane spent the last ten or twelve years of his life in retirement, and died in 1834. Sir Alexander Armstrong, afterwards Director-General of the Medical Department of the Admiralty, said of him that he might "justly be termed the Father of Naval Medical Science."

COLERIDGIAN "AMENITIES OF DEBATE."

MR. STEPHEN COLERIDGE used to boast of his tender regard for the "amenities of debate," a regard which he has consistently shown by his studied insolence and offensiveness towards all who ventured to express disapproval of his methods of controversy. We had almost forgotten him and his campaign against experimental research, but it appears that, as Beatrice says of Benedick, he will still be talking, though nobody marks him. In the March number of the *Zoophilist*, the wilderness in which his voice cries desolately, he attacked Sir Edward Schäfer for a leaflet published by the Research Defence Society, in which the distinguished Edinburgh professor points out that progress in medicine and surgery cannot be made without the help of animal experiment, and shows the inconsistency of those who are opposed to the use of that method and yet do not object to the exploitation of animals for the needs and luxuries of mankind. From this clear, straightforward statement of fact Mr. Coleridge detaches two or three passages and comments on them in a manner which obscures the issue. When Sir Edward Schäfer invited him to publish the whole document, which is quite short, in the *Zoophilist* and there criticize it as freely as he liked, Mr. Coleridge at first replied that this was "quite unreasonable," but he has since undertaken to reproduce it; he may then accept the rest of Sir Edward Schäfer's invitation, but so far there is no argument, hardly even a meaning, in what he is pleased to call his "criticisms." He speaks of "the unhappy pamphlet," and "this unhappy professor," and says that Sir Edward Schäfer "would really be better employed in trundling a hoop than in writing this kind of pamphlet!" Heine in his cynical confessions says that in the rapture of his Hegelian dream he regarded all who did not acknowledge

¹ Vol. I, 1915. A note on this paper appeared in the *BRITISH MEDICAL JOURNAL* of May 29th, 1915, p. 938.

his self-made godship as "unhappy" unbelievers. Mr Coleridge's manner of writing arouses a suspicion that he has come to hold a similar idea of himself. And this, unlike the poet, in all seriousness, for among the many gifts bestowed upon him in the cradle his fairy godmother left out humour. With an assumption of pity for which we are sure Sir Edward Schäfer will be duly grateful Mr. Coleridge says: "These professors, heaven help them, seem all to be blessed with the immature brains of babes and sucklings." We suppose this kind of stuff is accepted as argument by supporters of the National Antivivisection Society, or it would not be offered for their edification by their director and treasurer. But what a mentality it reveals in them and in him! And what right has he to complain of being "subjected to raucous bellowings of personal abuse"?

X-RAY PROTECTION.

WHEN the discussion on *x*-ray protection was resumed at the Röntgen Society's meeting on March 7th Dr. W. Harwood Nutt said that he was inclined to believe that the tired feeling of which *x*-ray workers complained was due not to ionization but to ozone, which, according to some qualitative tests, was liberated by *x* rays. Dr. G. B. Batten laid stress upon the danger of associating work with chemical substances, especially alkaline materials, with *x*-ray manipulation. He had noticed a dermatitis supervene in a case of ringworm which previously had been treated with picric acid. Major Wilson, Canadian Medical Corps, said that the ideas of British manufacturers with regard to protection were certainly below the standard deemed necessary with the heavy transformer outfits obtained from the United States and Canada. In the Canadian military hospitals the most complete rubber protection was insisted upon, and a layer of 8lb. lead (if possible a double layer) was passed round the tube box. The president (Mr. J. H. Gardiner) announced that the authorities of the National Physical Laboratory had stated that they were prepared to examine any protective material submitted to them, and to give a certificate upon its absorption coefficient.

Medical Notes in Parliament.

A Year of War.

MR. TENNANT'S STATEMENT.

On the Army Estimates, which were taken in the House of Commons on March 14th, the Under Secretary of State for War made his annual statement on the work of the department during the closing financial year. He dealt chiefly with administrative questions; the sums in the estimates were token votes of £1,000 each, but Mr. Tennant said that the vote was for four million men, and that the navy, army, and munition departments were together costing just over three millions a day.

Recruiting: Medical Examination.

After the first rush to the colours the rival claims of the munitions department and the general labour market caused the intake of recruits gradually to dwindle. As it was evident that special steps were needed, Lord Derby undertook his scheme, and though men came forward slowly at first the intake grew larger until it culminated in the attestation of one million recruits in four days. During the early stages of the war many men who desired to enlist concealed physical defects, but later there was a change. Under the group system some men had persuaded the doctors that they suffered from disabilities which were fanciful or imaginary, and had consequently been rejected. It had been necessary to tighten up the machinery and to make the conditions in regard to armlets more stringent. At a second medical examination a number of men had been found fit for general service. The medical standard had never been reduced; the efficiency of medical examination had been materially improved and the standard was now more strictly enforced; some men previously accepted for military service by medical practitioners had been rejected

by the medical boards set up in each military area. The war was a war of attrition, especially of men, and it became evident that everything should be done by grading men and putting them into categories to save those medically fit from doing what might be called supplementary duties; the first-rate men were released for fighting, and the men put into the reserve were able to return to their homes and businesses.

Pensions.

In dealing with the subject of pensions Mr. Tennant denied the allegation that the army pensions authorities had given no pensions for tuberculosis, frost-bite, rheumatism, heart disease, and epilepsy. In 1,932 cases of tuberculous disease pensions had been granted, and in 1,208 cases pensions had been refused. Of cases of frost-bite, 306 had been admitted to pensions, and so far as was known none had been rejected. Of cases of rheumatism, 891 had been admitted to pensions at the full rate, of cases of heart disease 1,431, and of cases of epilepsy 210. Soldiers discharged for injuries or wounds, or sunstroke received in action or in performance of military duty, or for blindness caused by military service, or disease due directly or indirectly to war service either abroad or at home, were given pensions at the full rates. There remained the cases of men who were discharged on account of disease which had been aggravated by service. It would be improper to pension from public funds men whose illness was neither caused nor aggravated by service. It might be said that none of those men should have been in the army, but during the first rush of recruits to the colours it was not possible to ascertain in every case that there was no organic trouble. Men had concealed their ailments—some from the best motive because they wished to fight for their country, some from very different motives. Of sixty men who came before the Chelsea board on February 24th, having been discharged from the army after periods of service extending from seven months to more than a year, not one had undergone any military training or even drill. They were men who had determined to get into the army in order to obtain free hospital treatment. It had been the habit of the Chelsea board to grant pensions at rates ranging from 4s. 8d. to 7s. a week to disabled soldiers whose condition had been aggravated by military service. It had been decided to increase the grant to four-fifths of the full pension. Orders had been issued to the labour exchanges which it was hoped would result in providing employment for discharged soldiers and supplying in some degree the labour for which employers were crying out.

Prisoners.

Arrangements made among the hostile Governments were tending to render the conditions for combatant and civilian prisoners of war better. Arrangements for the transfer of sick and wounded to Switzerland had been made. The camps in the German empire and in Austria-Hungary were under the inspection of the United States Ambassador and Consular Service, but, though the conditions were distinctly better, the ration was still very stinted. Prisoners in the Balkans had been assembled in Philippopolis and American doctors put in medical charge, and negotiations were in progress for the exchange of British prisoners in Turkish hands.

The Army Medical Service.

Turning to the question of the health of the troops, Mr. Tennant read a message from the General Officer Commanding-in-Chief the British Expeditionary Force in France, in the course of which he said that the forces in France had been increased "from a couple of corps to a large army, but the provision made for their wellbeing, whether in sickness or health, has continued to be all that could be wished. The result of the strenuous labour devoted to increasing and maintaining this army is that all are in good health and in good heart, and confident of victory." The medical service had been almost perfected. The incidence of disease in France was low; there had been an entire absence of any epidemic, and thanks were owed to the many scientific men who, by their energy and action, particularly in the prevention of disease, had helped to bring this about; splendid work had been done by the Sanitary Committee, especially in Gallipoli, where tropical diseases had been counteracted and an outbreak of dysentery and diarrhoea,

had caused very great anxiety. There was now no anxiety in relation to the troops either in Salonika or Egypt. At home large convalescent hospitals had been established; in the military hospitals men were being replaced by women, of whom 1,400 had already asked for general service. For that thanks were due to the Red Cross Society, and thanks were due also to between 5,000 and 6,000 women who had organized under Voluntary Aid Detachments.

The Medical War Committees.

"In order to obtain medical officers under conditions least harmful to the needs of the civil population and the great civil institutions, we have," Mr. Tennant said, "established a representative body of medical men in conjunction with the National Insurance Commissioners and the Local Government Board. This had done very valuable work." The National Insurance Commissioners had taken up the question of the early treatment of cases of tuberculosis removed from the army. The medical profession in general had come forward in the most admirable way to meet the needs of the State. Most successful measures had been taken against gas attacks.

France.

The medical services, said Mr. Tennant, had done a very great work, and he read a letter from Sir Frederick Treves as follows:

Those who are familiar with the medical dispositions in the South African war will find in this campaign an advance in the medical services so great and so wide extending as to amount to an actual revolution. Not only has the sick and wounded soldier never been so well cared for in any campaign as in the present, but it is difficult to suggest in what way his welfare could be further promoted.

Sir Frederick takes a couple of illustrations. He says:

We should note in the first instance such an advanced dressing station as that at Les Brebis. The place is a mining village well within range of the enemy's fire. Indeed, some twenty shells had fallen into the area on the morning of our visit. The hospital is a building which was used by the miners as an entertainment hall. This hall makes an excellent ward, provided with every necessary detail. Attached is a small, carefully equipped operation room, where operations of an urgent nature—such as the arrest of haemorrhage—could be carried out. Here also wounds may be cleansed and redressed, fractures more comfortably adjusted, and injections of antitetanic serum given. Close at hand were two dug-outs into which patients could be taken if the shelling threatened the building. The whole station was simple, efficient, and exactly equipped for its limited purpose. There was nothing lacking and yet nothing superfluous, and the feature of extreme mobility was kept prominently in mind.

Reference is made to clearing stations, and he alludes to one at Baillieu:

From a surgical point of view, these clearing stations represent the most important items in the general scheme for the treatment of the sick and wounded. They are as near the front as they can be placed; they are readily accessible from the advanced dressing stations; while they are in direct touch with the base either by a line of rail or by a good main road. The tents are well warmed by stoves and well lit by electric light, while the operating theatre is as well found as any in a civil hospital of its size. The huts at Remy and the wards at Baillieu could compare with the wards of any good civil hospital in England.

To these clearing stations wounded men can be brought in a few hours, and it is needless to point out that in the severest gunshot wounds prompt attention is the main factor in the saving of life and limb. In many cases a man in need of a grave operation has found himself on the operating table within three or four hours of his being shot. We were told of instances in which operations upon the skull and the abdomen had been carried out within two and a half hours of the receipt of the wound. Such prompt attention could not be obtained by a wounded civilian in any rural district in England. The patient not only finds himself in an operating theatre equipped with the best and most recent appliances, but in the case of every one of these hospitals he finds himself in the hands of an operating surgeon of the first order. The value of such service cannot be exaggerated. At the same time the patient has the advantage of the regular and frequent visits of a consulting surgeon of European reputation. Moreover, the nursing in these stations is of the highest type, being carried out by the army nursing sisters.

It must be remembered that a great number (and often the greater number) of the patients arrive at night, and that, over and over again, operations are carried out the whole night through. It must be noted also that vast shell wounds require constant and elaborate dressing that absorbs much time and can only be carried out by the surgeon himself. At Lapugny, with its 376 beds, no less than 2,000 casualties were dealt with in one day. We found that at the clearing station at Baillieu the vast number of 61,000 sick and wounded had passed the

hospital since it was opened, while the number of major operations reached to over 1,000.

In the hospitals we visited we found on all sides evidence that the sick and wounded soldier has the advantages of the latest advances in surgical science, the most modern equipment, and the most recent developments in bacteriological work.

Mr. Tennant added that he had himself seen the clearing stations of which Sir Frederick Treves spoke most highly, and had watched the ambulances full of wounded coming to them until he could watch them no longer—he was so deeply moved. These were the men who had answered the call of King and country, and were risking their lives every day in the great cause. Could the country be content that these men who sprang forward to answer the call should die in France and Flanders while every effort failed to induce others to perform their duty and join their comrades at the front? Those who were too tender with the difficulties which these men put forward should consider what effect expressions of sympathy with them would have upon the waverers, and the cost to the army and the public. A terrible responsibility rested upon them, because to encourage the waverer at home was to dishearten and bewilder the soldier at the front.

DISCUSSION.

The discussion which followed turned partly upon air policy, partly upon the alleged mismanagement in Mesopotamia, and partly upon the question of pensions.

Mesopotamia.

Mr. Hobhouse, who followed, asked for more precise information, and complained that Mr. Tennant had not dealt with the Gallipoli campaign and the expedition to Mesopotamia. With regard to the latter, the news which had filtered through during the course of the last fortnight was calculated to cause very serious alarm as to the condition both of the besieged and the relieving forces on the Tigris, and nothing was known as to what was going on at Salonika. Colonel Lockwood also complained that there had been no reference to the Mesopotamia expedition, as to which the public mind was at present intensely anxious. Very disagreeable rumours had come home as regards the treatment and care of the wounded in that expedition. It was well known that the care and attention bestowed on the wounded in France was magnificent, but private information he had received was to the effect that there was want of care of the wounded in Mesopotamia. Admitting the difficulties of the shortage of doctors, of the climate, and other drawbacks, he believed that more might have been done, and that more foresight might have been shown for the care of the wounded there. The expedition was for some time under the charge of the Indian Government, but he believed that now both the expedition and the medical care were under the charge of the War Office. Mr. Tennant interposing said, "Not the medical care." Colonel Lockwood said that in that case he would not be in order in pursuing the subject, but he was desirous that it should be known that the public was anxious, and had good reason to be anxious, as to the way in which the wounded there were being looked after. Mr. G. Lambert also complained that the advance on Bagdad had not been carefully thought out, and read a letter from an officer, whom he described as one of the most gallant in the British army. He had been wounded on January 13th or 14th, and he wrote:

I must consider myself fortunate to have arrived at Basra, where some medical aid was available, without getting a septic wound. The lot of the badly wounded during the evacuation stage from the field to the base at Basra is anything but joy. The five or six days spent on the paddle steamer down the Tigris are not to be forgotten in a hurry—two hundred, or possibly more, lying anyhow on the deck, with only one medical officer and practically no medical equipment. However, I understand that proper hospital steamers are now being sent out there.

Mr. Tennant interposed with the remark that the matter was one for the Indian Government and not for the War Office, but Mr. Lambert retorted that the War Office or the Army Council had assented to the advance, and must therefore be held responsible for the deeds of the Indian Government. He asked that the country should know how the wounded were progressing to-day in Mesopotamia.

Pensions.

Mr. Jowett (Labour) moved that the State should accept the responsibility for the payment of pensions and allowances to all soldiers discharged from the army on account

of diseases contracted or developed during service with the colours, and, in the case of death, pensions and allowances to the dependants. He maintained that the concessions announced by Mr. Tennant were insufficient, and strongly urged that they should be made retrospective. The motion was seconded by Mr. Hodge and supported in all parts of the House.

The Financial Secretary to the War Office, in his reply, began by saying that with a system of universal service there would have been a more complete and more satisfactory medical examination. When a man had been taken into the army and passed out of it, the question arose, was he or was he not entitled to a pension under the regulations of the Royal Warrant? That warrant was the verbal expression of the pension policy of the Government; if that changed the warrant changed, and he hoped it would be changed. The Board of Chelsea Hospital had full and free discretion to interpret the Royal Warrant, and it rested with that Board to decide to what a man was entitled in any particular case. He hoped that arrangements in contemplation would enable some payments to be made to a man between the time at which he was discharged and that at which his pension first became due. The Chelsea Commissioners had been able to deal with cases of aggravation of disease under another article of a Royal Warrant which enabled a lower scale of pensions to be given. The number of cases of tubercle contracted abroad was 1,226; of these, 1,180 had been pensioned, and only 46 had been rejected. The supposed analogy of the Workmen's Compensation Act should not be pushed too far; compensation could not be given in all cases of injury incurred while the man was not on military duty; but no one could look on the halt, and the maimed, and the blind without resolving that, at whatever cost, the country should see that none of them ever felt want. They should be treated as heroes; but there were men who could not be treated in that way—men whose disease was due to their own fault could not be brought within the terms of the motion; but he agreed that the terms of the warrant were not wide enough, and it had been decided that where a man's disease had been aggravated by, though not wholly and directly due to service, an extended authority should be given to the Chelsea Commissioners to allow a pension up to 20s., and that concession would be retrospective, men whose claims had been rejected being authorized to re-submit them. The motion was negatived, but Mr. Tennant's appeal to go into committee was disregarded and the debate was resumed on the following day, when it was directed chiefly to the calling up of married men, which Lord Kitchener, in the House of Lords, had said would in any case have become necessary within a few weeks. The arrangements in Mesopotamia and the general organization of the Army Medical Service also came in for criticism.

Army Medical Organization.

Mr. R. McNeill thought that Sir Frederick Treves's opinion quoted by Mr. Tennant must have been formed after visiting a clearing station or hospital in a certain section of the line, where provision for surgery was particularly well up to date, otherwise he did not know how the conflict of testimony could be accounted for, for there were other authorities hardly less eminent than Sir Frederick who gave a very different view. After giving a short account of the reorganization of the Army Medical Service which followed the South African war, Mr. McNeill alleged serious defects in its present administration which he traced to the failure to make use of the Army Medical Advisory Board. He alleged that Surgeon-General Macpherson was responsible for a terrible breakdown of the medical arrangements at the battle of Festubert. He was removed from the first army in France to another army, where he was responsible for a still greater failure at Loos. He was then removed to Salonika, where Mr. McNeill believed he still occupied a responsible post. Mr. McNeill proceeded to criticize the arrangement by which there were now two Directors-General, one in London and the other in France. He believed that, in consequence, it was a matter of chance whether arrangements made in London were carried out across the Channel. He considered the present organization of the Army Medical Service unsound, because it was based upon the combatant division as its

unit. That system was suitable to a mobile army, but not to one fixed, as the British army had been in France. When a division was moved a short distance it was absurd to move all its medical equipment; it should be retained in the place to serve with the incoming division. He believed the divisional system to have been responsible for the scandalous failure in some respects at Gallipoli, and for that which, if information now coming to hand was correct, was nearly as bad in Mesopotamia. He said that the selection of Poperinghe as the clearing station for the first battle of Ypres was unfortunate, as there was only one available road to it: troops and supplies blocked that road, and there was consequently great delay in getting away the wounded. At Hooge doctors of one division whose troops were engaged were working for thirty, forty, and even fifty hours on end. They were overworked, but they had worked as doctors had always worked throughout the campaign—with a devotion and energy and an industry beyond all praise so far as individuals were concerned. At the same time there were numbers of doctors actually in the town doing nothing simply because they belonged to other divisions. He alleged that of 200 patients from Ypres 80 were forgotten and left for seven days without medical attendance, yet all through the battle, owing, as was said, to some dispute between the R.A.M.C. and the Red Cross, there were numbers of motor ambulances doing nothing at Calais and Boulogne. That was early in the war, but at Loos thousands of wounded men were left lying all night in the open because hospitals were overfull and the staffs overworked, yet within a few miles there were hundreds of doctors of other divisions doing nothing, who could easily have been brought up by motor car. It was not the fault of the doctors, who were anxious to go, but of the system. A telegram was sent to the base for more doctors, but they were not allowed to start for four days while they were waiting to get the necessary papers signed. When they did arrive the wounded who had been suffering for want of attendance had been removed. Some days before the attack at Loos some of the field ambulances, probably under the direction of zealous men of common sense, collected a large number of stretchers, but Surgeon-General Macpherson ordered them to be taken away, because they were above the regulation number. These examples showed not only that the system was unsuitable for the fighting of to-day, but that it was administered with a rigid adherence to formula and rule. Further, the best use had not been made of the medical talent at the disposal of the nation; men of high professional attainments were enlisted and placed in junior posts. Instead of employing these men, who were in the prime of life and of their scientific knowledge and skill, in positions of command, the War Office brought back old pensioners of the R.A.M.C. and put these "dug-outs" in command. Under the present system it was impossible to get the rapidity necessary between the infliction of the wound and the operation. Motor transport had revolutionized conditions, and had rendered the field hospitals close to the front useless. There ought to be, in their place, all the way along the front, a system of movable hospitals, combining the functions of the field hospitals and the clearing stations, and within easy access, by motor car, of the firing line. Each ought to be in charge of a first-rate surgeon, and thoroughly equipped for up-to-date surgery. They should be established off the main road, which must be kept clear for the transport of supplies and troops, and should have easy lateral communications between one part of the line and another. This would make it possible to do away with the field hospitals and field ambulances. He considered that Sir Frederick Treves's statement that operations could be performed within two or three hours of the casualty referred to quite exceptional circumstances. The opinions he had expressed were those held by a very large body of highly instructed medical opinion. He hoped that the Government would appoint three or four thoroughly competent persons—not necessarily doctors, but perhaps including one doctor—to go to France to visit the hospitals there, to examine practitioners who have been in those hospitals and at the front, and to report whether there had not been a very considerable and unavoidable breakdown. Major Astor, who followed, said that he had seen a good deal of the medical service unofficially, was

associated with a fairly big hospital and had seen the way in which the wounded were brought over from France and the way they were landed at Southampton, and had visited some of the hospitals. From this experience he did not think matters were as black and serious as Mr. McNeill had painted them. He paid a tribute to Sir Alfred Keogh, whom he had found singularly accessible, anxious to investigate any question, whether large or small, and particularly fresh in mind.

Mesopotamia.

Mr. Long, who, in the absence of the Premier and the Secretary of State for India owing to illness, replied for the Government, admitted that serious defects had been disclosed in Mesopotamia. The Viceroy and the Commander-in-Chief in India had some weeks ago decided to send Sir William Vincent, a distinguished Indian Civil servant, and General Bingley, an Indian officer, to Mesopotamia to conduct an inquiry into the medical arrangements, and to make good deficiencies. The War Office had already supplied two Indian general hospitals complete and the personnel of two more, a British stationary hospital with 400 beds, and a British general hospital with 1,040 beds. During the last month 100 doctors and 100 orderlies had been sent, and the War Office had offered to meet, and believed it was able to meet, any demands that could be made upon it. Whatever reason there might be to believe the stories that reached this country, no effort had been spared, or would be spared, to do everything that should be done and ought to be done in the circumstances.

The Speaker was got out of the chair after dinner and the House went into Committee on the Estimates.

War.

Medical Examination of Recruits.—In reply to a question by Mr. Anderson, on March 8th, the Financial Secretary to the War Office said that subject to certain limitations, the usual fee for medical examination was 2s. 6d. a man. If within three months the man was found to have been improperly passed the doctor was liable to refund the fee. In reply to further questions on the following day, Mr. Tennant stated that he was glad to have the opportunity of contradicting categorically the statement that recruiting medical officers were paid only for recruits they passed as sound. It was the examination that was paid for, and the pecuniary result to the examining medical officer was the same whether he accepted or rejected a recruit. This had already been stated on several occasions. A medical man holding a commission received no fees for the examination of recruits. Mr. Snowden, who asked one of the questions, alleged that recently men had been passed as fit for military service who had artificial legs; who were so mentally deficient that they were unable to understand or answer any question; or who had never done any work for years on account of daily attacks of epilepsy. Mr. Tennant, in his reply, said he could not accept such statements as being anything else than an incorrect representation of the results of the work of the examining medical officers. "I think," he said, "that instead of being held up to obloquy they deserve support and recognition in the heavy work they are patriotically doing on behalf of the country."

Medical Unfitness.—In a written reply to Mr. Crooks, who asked whether a man certified as medically unfit on Army Form B 2512A by an officer R.A.M.C. at a recruiting office since August 14th was entitled to an armet, Mr. Tennant stated that an armet was only given to men who had been rejected as medically unfit, if, on re-examination, they were found to be suffering from serious organic disease. If, on re-examination, they were not found to be so suffering, they were attested, and classified in their category in the reserve.

Lunacy Institutions.—In written replies to questions addressed to the Home Office, Mr. Brace has stated that the new Hampshire Asylum is to be used by the military authorities as a hospital for sick and wounded soldiers, and not for cases of nervous and mental affections. The whole of the Middlesex County Asylum at Napsbury was being handed over to the War Office, and the patients under treatment there were being distributed over other asylums as near as practicable to Middlesex. The asylum will be used for sick and wounded soldiers, but it is still intended to receive there a certain number of soldiers suffering from nervous and mental affections of the same type as those now under treatment in the detached part of the institution already adapted as a war hospital. In reply to other

questions with regard to lunatic asylums the President of the Local Government Board has stated that two of the Commissioners of the Board of Control had, at the request of the War Office, undertaken the continuous supervision of the scheme for the use of certain asylums as war hospitals, and had thus, to a large extent, been withdrawn from their ordinary functions. Another commissioner and one of the inspectors had been absent on military duty since the beginning of the war, and more than half the clerical staff had joined the forces. The work of the commissioners in connexion with lunacy had been increased rather than diminished by the handing over of lunatic asylums for use as war hospitals. The concentration of patients into a smaller number of asylums had not diminished their number, had demanded even closer supervision than formerly, and had involved difficult administrative and financial arrangements. The expenditure of the Board had been reduced in many directions, and the estimates for the coming year would show a large reduction.

Officers' Income Tax.—In reply to a question by Mr. Bennett-Goldney, on March 9th, Mr. McKenna said that the method of paying income tax by deduction from salary was applicable to all Government servants, and was not confined to naval and military officers. In reply to a suggestion in the question that he would so adjust the new income tax regulations that the pay of all officers amounting to and including £400 a year should be exempt from income tax, Mr. McKenna said that he was unable to anticipate his next financial statement.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

In the list of casualties issued by the Admiralty on March 9th as occurring in consequence of the sinking of the mine sweeper H.M.S. *Arabis* on February 11th, is the name of Surgeon Probationer John Hughes, R.N.V.R., unofficially reported to have died as a prisoner. It has been stated in the press that Mr. Hughes died from exposure, and was buried in the naval garrison cemetery at Wilhelmshaven with military honours.

ARMY.

Wounded.

Captain S. S. Greaves, R.A.M.C.(T.F.), France.

DEATHS AMONG SONS OF MEDICAL MEN.

Beale, Clifford William, Lieutenant 7th Royal Sussex Regiment, who was killed on March 2nd, aged 23, was the only son of Dr. and Mrs. Clifford Beale, of Allon Down, Rotherfield, Sussex, and nephew of Sir W. Phipson Beale, Bt., K.C., M.P. He was educated at Warren Hill, Eastbourne, and at Harrow (Sir Arthur Horth's House), subsequently obtaining a scholarship at Gonville and Caius College, Cambridge. He shot for Harrow at Bisley, and was an active member of the O.T.C. both at school and college. He graduated in the Natural Sciences Tripos at Cambridge in 1914, and was captain of his college boat club and of the crew which won the Thames Cup at Henley in the same year. He enlisted as a private in the Public Schools and Universities Battalion, but subsequently obtained a commission in the 7th Royal Sussex Regiment, with which he had been serving abroad since last May. He was gazetted lieutenant in January, 1915, and had recently been appointed to a light mortar battery.

Bowhay, Eustace G., Captain 1/6th Battalion Devonshire Regiment (T.F.), killed in action in Mesopotamia on March 8th, was the second son of Dr. Bowhay, Gunnislake, Tavistock, and was 26 years of age. Educated at Skinners' School, Tunbridge Wells, he was gazetted to the 5th Duke of Cornwall's Light Infantry in 1909 and transferred to the Devon Regiment in 1913. He obtained his company shortly before proceeding to India in October, 1914. Captain Bowhay was in practice as a solicitor at Torrington, North Devon. He was clerk to the borough magistrates and steward of the town and alms land charities.

Johnston, H. A., Second Lieutenant Royal Flying Corps, son of Dr. Johnston of Stranorlar, County Donegal, killed in France on March 4th, aged 24. He was educated at Trinity College, Dublin, and before the war was a wireless installation expert in the firm of Siemens and Co. Enlisting early in the war, he got a commission a year later. He was killed by a shell while on leave for the day.

Mason, Arthur Edward Knight, Captain 7th, attached 8th, Battalion, Royal Fusiliers, only son of Dr. Arthur Mason, Oakwood, Walton-on-Thames, killed in France on March 2nd, aged 22. He was educated at Cheltenham and at Exeter College, Oxford, and got his first commission on August 15th, 1914, was promoted to lieutenant on February 2nd, 1915, and recently to captain. He had previously been wounded in April.

MEDICAL STUDENT.

Sangster, William Campbell, Lieutenant 4th Battalion Gordon Highlanders, reported missing on September 25th, 1915, was killed in action on that date. He was the son of Mr. William Sangster of Rubislaw, was a graduate in Arts of Aberdeen

University, had entered as a medical student, and when war broke out was commencing his second year. He received his commission as second lieutenant in the 24th Battalion on October 4th, 1914, was transferred to the 14th Battalion in June, 1915, and went to the front almost immediately.

NOTES.

LIEUTENANT-COLONEL W. H. WILLCOX, R.A.M.C., M.D., F.R.C.P., has been appointed consulting physician to the Mesopotamia Expeditionary Force, with rank of Colonel.

ANGLO-RUSSIAN HOSPITAL.

Dr. T. J. Horder, who was appointed physician to the Anglo-Russian Hospital, is serving as medical adviser in London to the hospital. Dr. Gould May is acting as physician to the hospital in Petrograd.

Lieutenant-Colonel T. E. Sandall, who was invested with the C.M.G. by the King on March 11th, had practised at Alford, Lincolnshire, down to the time when the Territorial Force was mobilized at the beginning of the war. He was then lieutenant-colonel commanding the 5th (Territorial Battalion) of the Lincolnshire Regiment, and had received the Territorial decoration. While commanding his battalion in France he was wounded, but is now convalescent. He graduated M.B., B.C. Cambridge in 1895.

HONOURS.

The list of officers commended for service in action, mentioned in dispatches from the Vice-Admiral Commanding the Eastern Mediterranean Squadron covering operations in the Gallipoli Peninsula, contains the names of Deputy-Surgeon General O. W. Andrews, M.B., R.N., and Fleet Surgeon John Menary, R.N. The list of commendations also contains the name of Midshipman H. D. Johnston, R.N., the son of Dr. R. McKenzie Johnston of Edinburgh, who has been awarded the D.S.O. He was assistant to Commander Swabey, Naval Observation Officer, Cape Helles, since July, 1915, and the distinction has been conferred upon him for having "shown great ability and resource in his most important duties."

MEDICAL OFFICERS WANTED.

3/1st Notts and Derby Mounted Brigade Field Ambulance, R.A.M.C.(T.F.).

A medical officer is required for this unit; promotion to temporary captain after six months' approved service. Applications to Officer Commanding, No. 9 Lines, Rugeley Camp, Staffs.

3/2nd South Midland Mounted Brigade Field Ambulance.

A medical officer is required for this unit. Full particulars on application to Captain A. G. Levy, Commanding 3/2nd South Midland Mounted Brigade Field Ambulance, 1, Ilfley Road, Oxford.

2/1st South Midland Mounted Brigade.

Three medical officers are wanted to complete Brigade at present on East Coast. Applications to Major D. M. Spring, S.M.O., R.A.M.C.(T.F.), Head Quarters, Hempton, Fakenham, Norfolk.

2/2nd South Midland Brigade Field Ambulance.

Medical officers are urgently required for this ambulance, stationed at King's Lynn. Must sign for foreign service. Applications to Major H. G. Magrath, O.C., London Road, King's Lynn.

Ireland.

THE committee in charge of the testimonial to Dr. Power of Ardinnan has decided not to close the fund until March 25th, and asks intending subscribers to send their subscriptions as soon as possible to Dr. J. H. Jellett (Treasurer), 11, Beresford Place, Waterford.

Last week Dr. John L. Power, dispensary medical officer, Castlemartyr, who has joined the R.A.M.C., was entertained to dinner at Mogeely, and a presentation was made to him on behalf of the people of the district.

The medical practitioners of the county Wexford presented a silver tea and coffee service to Dr. William W. Murphy, Coolgreany, in recognition of the able services he has rendered for twenty years, not alone to the local profession in county Wexford but to the entire profession in Ireland, with whom he is most popular.

At a meeting of county Wexford medical practitioners on March 1st the following resolution was unanimously passed:

That at this our first meeting since the settlement of the certification question, we, the county Wexford medical practitioners, wish to record our appreciation of the valuable services rendered to the whole profession in Ireland by our able, worthy, and tireless friend, Dr. Thomas Hennessy, and hereby tender him our very best thanks for his able and painstaking care of our interests, and congratulate him personally on the success of his tactics.

At the last meeting of the Swinford guardians a letter was read from the Local Government Board declining to sanction the appointment of Dr. Martin Sweeney permanently as medical officer for the Charlestown dispensary district. The Board considered that it would not be fair that in the absence of men who had volunteered for service in the army, young men should secure election to vacancies which may arise. Dr. Sweeney refused to act temporarily, and it was agreed to advertise for a temporary medical officer.

In the White Paper issued last week regarding the Civil Service Estimates for the coming financial year, the amount estimated to be required for hospitals and charities in Ireland is £16,778, a decrease of £75 on the present year. The grants to the various hospitals remain unchanged. The grants to public infirmaries are unchanged at £223.

A number of vaccination defaulters have been prosecuted recently in Queen's county. At Abbeyleix the magistrates allowed the charges to be withdrawn on the defendants undertaking to have the children vaccinated within a fortnight. At Maryborough fines of 10s. and costs were imposed in nineteen cases, nine others were adjourned, and in seventeen the summonses were withdrawn owing to defective service of notices.

THE DANGER OF SMALL-POX.

Sir Charles Cameron has written to the public press drawing attention to the fact that small-pox is spreading in England, and has visited Manchester, Salford, and Cardiff, towns with which Dublin is in daily communication. It is to be regretted, he says, that the belief in the efficacy of vaccination in the prevention of small-pox, and of its power to lessen the severity of its symptoms, has seriously declined of late years. This, he thinks, may be partly due to freedom from the disease for some years past. It is certain that there are many unvaccinated persons in Dublin, and the hope is expressed that boards of guardians will enforce the provisions of the Vaccination Act.

Scotland.

At the meeting of the Royal Society of Edinburgh, on Monday, March 6th, the following medical men were amongst the new Fellows elected: Percy Theodore Herring, M.D., F.R.C.P.Ed., Professor of Physiology, St. Andrews, and Robert Muir, M.A., M.D., Sc.D., F.R.S., Professor of Pathology, University of Glasgow.

A Scottish Red Cross hospital ship, the *St. Margaret of Scotland*, destined for service in Eastern waters, is now ready. She is a vessel of 2,300 tons, originally employed in the inter-colonial mail service in the West Indies. She has been converted into a hospital ship under the superintendence of an Admiralty representative. The cost has been defrayed out of the flag day of the Scottish branch of the Red Cross Society last October, by which the sum of £21,000 was realized. She has accommodation for ninety-two patients in seven wards, named Clyde, Forth, Tay, Tweed, Dee, Spey, and Doon; over eighty emergency hammocks can be slung. Sir George Beatson, speaking at an inspection of the boat on March 7th, said that she was the latest example of the equipment of a hospital ship.

At a meeting of the Glasgow School Board on March 9th a resolution was proposed by Mr. G. D. Hardie and seconded by Dr. Grant Andrew in favour of taking steps immediately to provide classes, as centrally situated as possible, for children of school age suffering from myopia and defective sight. The proposal was referred to the special schools and medical inspection committees for consideration.

Correspondence.

MEDICAL RECRUITING: ENROLMENT.

SIR,—The Secretaries of the Central Medical War Committee have been good enough to suggest that I should write to you and state what the medical men in my area have done in connexion with their appeal for enrolment.

We called a meeting, at which were present all the doctors in the district except those already holding commissions or working in hospitals in France, and, after due discussion, by the unanimous vote of all those of military age it was decided that every man should forthwith enrol.

This they have done. Needless to say, it is out of the question that they all can be spared or that they all feel their circumstances permit them to go; but they have enrolled, intending that their district should do its share, and trusting to the conditions laid down in the Committee's circular of February 17th to the effect that only those who can be spared with due regard to the needs of the community should be required to go, that the difficulties of those whose ties make leaving their practices a *serious* hardship shall be considered by the Local Medical War Committee, and that finally they should not be called up unless the response to the call for enrolment from men of military age throughout the country justifies it.

It should be a simple matter to call a meeting of medical men in each area to confer over the question of enrolment, as we have done. Our members are few in comparison with those in many districts, which simplified matters for us. But though unanimity is not to be expected everywhere, such meetings and discussions would be an immense help to the work of the Central Medical War Committee. As the Secretaries say in their letter to me, "All difficulties would disappear could we count on such loyalty and foresight in every area." Being personally well past military age, I may safely quote this remark.—I am, etc.,

F. CLAUDE EVILL,

Chairman, Barnet and District Local
Medical War Committee.

High Barnet, Mar. 15th.

GUNSHOT WOUNDS OF THE HEAD.

SIR,—The observations published by Colonel H. M. W. Gray in the *JOURNAL* of February 19th (p. 261) will be read with interest by a large number of surgeons who are now called upon, or may be called upon in the future, to deal with a very serious group of war injuries. I am not competent to criticize those observations bearing on such surgical methods of procedure as are best calculated to prevent sepsis, but there are some statements made and some advice given in Colonel Gray's paper which, from a neurological and pathological point of view, can hardly be accepted without hesitation. One of the principles enunciated at the beginning of the paper is couched in the following terms:

That we can prevent permanent disability in most cases by systematically removing foreign material or displaced bone from the surface or substance of the brain whenever these are accessible to legitimate surgery.

This is a remarkable statement as it stands, and still more remarkable when we realize that "permanent disability" must include various forms of paralysis, disorders of speech, disorders of the special senses, and traumatic epilepsy, as well as mental derangement, and that no evidence is offered as to the permanent condition of his cases after the "complete" operation he so strongly advocates. It is the permanent condition of these unfortunate victims of the war which chiefly interests us, and upon which claims for the superiority of any particular method of treatment must surely be based. Those of us who are watching and treating these patients after their removal from the base hospitals may form in the course of time some opinion as to the accuracy of Colonel Gray's claim. Meanwhile, I cannot help feeling that some of his principles are founded on the old fallacy that the presence of foreign material rather than the injury to brain substance is the origin of such disorders of function as paralysis and epilepsy.

Let me enunciate a few principles which can hardly be

contradicted, and which may be useful for surgeons to remember when dealing with head injuries.

When a foreign body penetrates the brain substance it either carries with it infection or it does not. In the former case there is reason to believe that those parts of the track through which the foreign body has passed lying nearest the surface are more infected than those lying at a greater depth, and the removal of the foreign body will not remove the infection, although it may sometimes favour the action of the surrounding healthy tissue in overcoming the raid of sepsis. Whether it is a source of infection or not the foreign body cannot be removed without additional destruction of the brain, the results of which are often permanent. At the present moment there must be hundreds of patients in England with pieces of metal in their brains which are not producing symptoms, and only future records and statistics can decide how far the presence of these foreign bodies is harmful. Who knows whether there may not be an advantage in the possession of a foreign body inaccessible to legitimate surgery? The amount of permanent paralysis, loss of speech, loss of vision, etc., must depend on the amount of destruction of brain tissue, whether produced by the missile, by pieces of bone, by the surgeon's finger and scoop, or by sepsis. In some cases sepsis is the most dangerous enemy, in others the surgeon's finger and scoop. Missile and bone will destroy brain tissue whether we desire it or not, but in most cases the track of destruction caused by the surgeon will be greater than that of other foreign bodies. From these data it is only fair to conclude that each case should be considered and dealt with on its own merits, and that the general advocacy of "complete operation"—with its somewhat sinister but vague meaning—is dangerous advice to offer on the plea of preventing permanent disability.

The next point of importance is the question of opening the intact dura on the supposition or chance that it covers injured brain tissue.

The pulped area—a mixture of useless brain matter and blood—is an immediate source of irritation to the surrounding brain, because it is virtually a foreign body. In the process of healing a great part of it is replaced by fibrous tissue—a scar—which forms a remote source of irritation.

This statement is bald and unconvincing when offered as a reason for opening the dura by a small crucial incision made by plunging the knife in for half an inch or so, with the result that pulped material or healthy brain matter wells out like grease from a collapsible tube. The following questions are pertinent in this connexion. What evidence of pulping of the brain can be obtained before opening the dura? How is the fact that the brain matter is useless recognized? What evidence is there that softened brain tissue is a source of irritation? Can the formation of a scar be prevented if the brain is really necrosed, and is not the scar much more likely to be "fibrous" when the damaged dura is involved than when that membrane is left intact?

In cases of cerebral haemorrhage, of cerebral softening, or of encephalitis no one would advocate the removal of useless brain matter and blood, and experience teaches us that the brain is quite capable of dealing with either by its own natural methods. If pressure must be relieved a lumbar puncture is the first remedy, and not one to be postponed until large masses of brain matter—much of which may be only temporarily injured—have been squeezed through a small opening, and encouraged to find a place in the sun by means of a pair of forceps.

The fear of epilepsy is very real, but no one has yet explained on what pathological basis this more remote complication depends; it certainly does not depend on the size of the scar. There is some reason to suppose that epilepsy is more likely to supervene when the scar involves the dura than when it does not. Probably it depends more on individual idiosyncrasy than on any other factor, and I am in the habit of prescribing many months of bromide treatment for all cases of brain laceration or bruising as a prophylactic measure.

There was prevalent some years ago, and it still lingers in some minds, an idea that traumatic epilepsy can be cured by operation if the surgeon can find a scar on the brain and remove it. For some reason or other the fact that another scar would replace the one excised was overlooked, and the temporary absence of fits over a period of some

months has often led to the premature belief that a cure has been achieved. I am sorry to say that I have never seen a case of traumatic epilepsy cured by such an operation, and that I have seen many patients the worse for the attempt. From this experience I conclude that it is wise to let the brain deal with its own necrosed tissue in its own way, and that the less the surgeon interferes the more "glial" and the less "fibrous" will be the resulting scar; for scar there must be.

Moreover, a careful neurological investigation of the patient will often reveal the fact that the brain has been injured, perhaps pulped, in parts quite remote from the site of the direct injury, and in order to be consistent those areas, if Colonel Gray's advice be followed, should be exposed by trephining and incision of the dura mater.

On page 262 Colonel Gray has a short paragraph on "Operations where wounds of the blood sinuses are present." It commences with the statement that these are done as a matter of course, because it is thought advisable to remove fragments of bone which cause obstruction to the return of blood from any part of the brain. I am tempted to inquire whether the removal of the depressed bone is attended by a return of the venous circulation or whether the surgeon is not forced in the course of his operation to promote further thrombosis in order to check the alarming hæmorrhage which may occur when the sinus is exposed. The only harm caused by the depressed bone may be interference with the circulation in the lacunae and cortical veins, and the remedy proposed is calculated to make this condition irremediable. Colonel Gray says that out of fourteen cases operated on only one died, but it is the permanent result which interests us, and I should like to show him the extraordinary recoveries which are made by some of these cases which have never been operated on. Nothing has impressed me more in connexion with the cranial surgery of the war than the success of the conservative methods adopted and advocated by many British and French surgeons, not only in these cases but in dealing with depressed bone and foreign bodies as a whole. In their practice surgical interference is considered from the point of view of the brain rather than that of the skull or of the foreign body.

The *post hoc propter hoc* method of reasoning is notoriously misleading, and the mere fact that a patient recovers from paralysis after an operation is not sufficient to credit the operation with the achievement. It is an almost daily medical experience of civil life to see paralysis clearing up in a few hours or a few days without any operation. On the other hand, it cannot be denied that the opening of an intact dura and the attempt to remove foreign bodies must often destroy more or less healthy brain tissue, with all the inevitable results which follow such destruction. For this reason it is difficult to urge too strongly that each case should be treated on its merits, and that no authoritative dictum in favour of complete operations should be allowed to bias the surgeon in his difficult task.—I am, etc.,

London, W., Mar. 13th.

E. FARQUHAR BUZZARD.

DELAYED TETANUS.

SIR,—Quite recently four cases of tetanus occurring in soldiers at apparently long intervals after being wounded have been reported, namely, one by Dr. Penhallow from the American hospital at Paignton,¹ three by Lieutenant-Colonel Gilbert Barling from Birmingham;² these cases are respectively stated, the first as "a case occurring two months after being wounded," and the other three as cases with "incubation" of fifty-one, fifty-three, and forty days respectively.

I venture to suggest that three at any rate of these cases are cases not of long incubation of tetanus but rather of prolonged presence in the wounds of anaerobic organisms—that is, they belong to the class of cases to which attention has been drawn by Colonel Bond of Leicester. In passing, I may say that I have seen a good number of cases in which there has been evidence of the prolonged presence of quiescent organisms; how long they may stay I know not. One case that came under my care suggests a very long time, and is worth referring to.

A man with a compound gunshot wound of the thigh inflicted on April 25th, 1915, was treated in an auxiliary hospital; operations were performed on May 3rd, June 13th, and July 16th, 1915. He was sent to Netley healed and sound on November 19th, 1915, 208 days after the original injury. A few days later he fell down and refractured his thigh, the temperature rose, the thigh became swollen, and the scar suddenly gave way with a severe hæmorrhage. A large gas-containing abscess was found in which the gangrenous femoral artery had given way. In my absence Captain Woods ligatured the common femoral at Poupert's ligament and the man has made an uninterrupted recovery.

This is the longest persistence of gas-forming organisms that I have come across.

Dr. Penhallow's case of tetanus was given other on December 4th to overcome some deformities. Pain in the masseters occurred a week later, and still five days later definite tetanus occurred. Is not this a case of Colonel Bond's residual germs with tetanus of twelve days' incubation? Similarly, in Colonel Barling's first case, an abscess was opened on September 24th, ten days before tetanus appeared; his second case had a sharp foreign body removed on November 13th, four days before the onset of tetanus. In Colonel Barling's last case the wound was healed on October 27th; tetanus appeared on November 3rd; there is no record of any fresh trauma after the infliction of the original wound, and if none such occurred this would seem to be a definite case of prolonged "incubation."

I now come to the point which has induced me to pen these lines: It is to draw attention to the grave danger of any trauma to a granulating surface where there is a possibility of the presence of tetanus organisms.

In a small series of cases of tetanus which I hope to publish later is one of a man, apparently otherwise doing well, who had a slight rise of temperature, which appeared to be due to insufficient drainage of his wounds, which were on either side of the leg and communicated fairly freely. With a threaded probe I passed a drainage tube through with perfect ease and without using the slightest force. There ensued a slight fall in temperature, but his tetanic symptoms rapidly became much worse, and the temperature shortly began to rise rapidly. The attack of tetanus assumed an exceedingly acute form, and death occurred in about eighteen hours with a temperature of 109°, and, on retaking for verification, of 109.4°.

Evidently the trifling act of slipping a drainage tube through this man's wound led to the absorption of a fatal dose of the tetanus poison present. I have since been careful not to interfere with wounds in tetanus patients, and "to let sleeping dogs lie."—I am, etc.,

RUSSELL COOMBE, Major R.A.M.C.(T.),

March 13th.

Operating Surgeon, Netley Hospital.

MURMURS IN THE RECRUIT'S HEART.

SIR,—I have followed with interest the discussion on Sir James Mackenzie's memorandum. The crux of the matter, so far as murmurs are concerned, lies in the words: "If the candidate's response to effort be normal and the heart normal in size the murmur is negligible." (Obviously systolic murmurs only are referred to.) This sentence admirably sums up the new teaching on the subject. Now the question is whether the new teaching is right.

My reasons for this letter are three. First, I know some examiners cannot make certain of the size of the heart. Secondly, I am seeing in men back from the front—and indeed in some who have never gone abroad—not hearts with negligible murmurs which have defied strain, but hearts with serious murmurs which ought never to have been passed—even aortic regurgitation (the lesion which the binaural stethoscope is so apt to miss) and mitral stenosis; one wonders how many remain abroad permanently. So that one questions the practical wisdom of any teaching which belittles the importance of murmurs. Thirdly, I do not admit that the knowledge gained during recent years has scrapped all that went before. To claim that is merely to repeat the cry of every new dogma. I do not think we can examine a heart almost without a stethoscope, as some appear to imagine. In the heart, as elsewhere, there must be the little rifts within the lute, and it does not seem common sense to widen them, although they cause no uneasiness in civil life, nor, as yet, any discoverable cardiac enlargement.

I would urge not only keenness for numbers, but caution in their selection. Any well-educated medical man knows of systolic murmurs which he can regard as unimportant—

¹ *Lancet*, February 26th, 1916, p. 464.

² *BRITISH MEDICAL JOURNAL*, March 4th, 1916, p. 337.

for example, one class to which Sir James Kingston Fowler has drawn attention, the so-called "respiratory murmurs." Where a murmur is reasonably in doubt, the recruit should be given the benefit of that doubt. It is not well to be rash with other people's risks.—I am, etc.,

Exeter, March 11th.

W. GORDON.

VISUAL NEUROSES OF MINERS.

SIR,—I do not desire to lay any stress on the mere title of my paper, "Visual neuroses of miners." My only reason for adopting it was that I felt strongly that too much stress had been laid on the presence of nystagmus in these cases, which at best is only a symptom, and which seemed to me to have prevented due attention being given to the disease by neurologists and physicians generally, who should undertake its treatment.

I should like, on the other hand, to emphasize the fact that I was describing the disease commonly known as "miner's nystagmus." I do not intend to suggest that a change of nomenclature should be made, as the malady has been too long known under this title to render an alteration convenient.

I must, however, express my surprise that Dr. J. A. Wilson should say in his letter (March 11th, p. 397) that "in 200 cases of nystagmus collected in a coal-mining area only 12 per cent. were miners." I must leave an answer to this statement to some of the many able men who have studied this subject in mining districts, as I have been unable to do. If Dr. Wilson's contention were really accurate—that the whole train of symptoms which Dr. Llewellyn has given as denoting miner's nystagmus can be found to be more prevalent in the general population than in miners—we shall have reached almost a *reductio ad absurdum*.—I am, etc.,

March 13th.

CHARLES F. HARFORD.

Obituary.

ARCHIBALD CARMICHAEL, M.D.,

BARROW.

DR. ARCHIBALD CARMICHAEL of Barrow-in-Furness, who died at Perth on February 22nd, graduated M.A. Aberd. in 1868, M.B. in 1871, and M.D. in 1873. He went to Barrow in 1871, and two years later joined the late Dr. Stark in partnership. He was appointed honorary surgeon to the North Lonsdale Hospital at Barrow, and was closely identified with that institution down to 1901, when he retired from the active staff, and was appointed consulting surgeon. He was certifying factory surgeon and medical referee under the Workmen's Compensation Act. In addition to a large practice, he had an extensive consulting connexion and was an enthusiastic member of the local clinical society. Although he never consented to accept any office in the British Medical Association, he was always deeply interested in its welfare. He was a strong opponent of the Insurance Act, and refused to join the panel. Some six months ago he was compelled by failing health to take a prolonged holiday. He hoped to return to Barrow to continue his consulting practice. Whilst walking near Perth, where he was staying with his sisters, he died suddenly by the roadside. By his death the profession in Barrow has lost a distinguished member and valued friend. The funeral took place at Perth on February 25th.

DR. SETTLE WRITES:

Being one who knew the late Dr. Carmichael perhaps longer and more closely than any one else in the profession, I have been asked by his friends here to speak of him as I knew him. His coming to Barrow was synchronous with mine about forty-five years ago. His success and reputation soon caused him to be appointed honorary surgeon to the North Lonsdale Hospital, where his care and skill as an operator combined with the merit of his private work to make him well known by the prospective sick of North Lonsdale, so that to his general work was soon added a wide and lucrative consulting practice. Dr. Carmichael's work was marked by carefulness, and, like many of exceptional merit, he was a modest man. His work was honest work, and, unlike the practice of

many of less merit, he refrained from the adventitious aid of reporting and pamphleteering. His modesty also prevented him taking up public positions. Even in our local clinical society, of which he was a devoted member, he seemed to enjoy most to be a simple member, although his ripe experience, exhibited when he joined the discussions, added greatly to their value. In politics he was Conservative. In religion I believe he belonged to an old Roman Catholic family, but I understand scientific reading had disturbed his allegiance to that Church. Many years ago I had occasion to see the late Sir Jonathan Hutchinson. Our business being finished, he spoke to me in high terms of admiration of Dr. Carmichael's merits. I believe Dr. Carmichael died as he expected and hoped he would die.

THE LATE DR. R. DRUMMOND MAXWELL.—Dr. H. R. Andrews writes: "I should like to add a few words to what was said in last week's number about my late colleague. After holding the appointments of house-physician, house-surgeon, and receiving-room officer at the London Hospital, Maxwell served as civil surgeon in South Africa. At the end of the war he became resident medical officer at Queen Charlotte's Hospital. He developed at this period of his life a solidity of character and a continuity of purpose which impressed those with whom he worked. From this time onwards he devoted himself to obstetrics and gynaecology. For some years he attended most regularly all the gynaecological operations at the London Hospital, though there was no prospect of a vacancy on the staff, and soon constituted himself as a sort of unofficial registrar, and a very useful one. In 1907 he was appointed obstetric registrar and tutor at the London Hospital. From that time until his death he worked with me almost continuously and always harmoniously. In 1912 he was appointed assistant obstetric physician. He was a loyal, cheery, and unselfish colleague, an able and popular teacher, and a skilful and successful operator. For the greater part of last year, during my illness, he bore the burden of the obstetrical and gynaecological department of the London Hospital with little assistance, working unselfishly and cheerfully, although he longed to go out to France. During the last few months he had taken up physical culture with much energy, and used to swim twelve lengths of a swimming bath every evening, and sprint afterwards, besides doing various exercises. He told me a few weeks ago that he had derived great benefit from this, and that his sense of bodily fitness had not been so great for some years. The end came with shocking suddenness. On Saturday, March 4th, he wrote to the hospital saying that he would operate as usual on the following Monday. On the morning of Sunday, March 5th, he was operated on, and he died twenty-four hours later. His loss will be long and deeply felt at the London Hospital, and is a very real one to me. He was an enthusiastic member of the Gynaecological Visiting Society, no meeting of which could be considered to be complete without his lively and stimulating presence." We may add that he was elected assistant surgeon to the Samaritan Hospital in 1908, resigning when he was appointed assistant physician to the London Hospital.

THE LATE LIEUTENANT BERNARD B. GOUGH, R.A.M.C.—Staff Surgeon W. Kenneth Wills, M.B., R.N.V.R., has sent the following appreciation:

To have known Gough for a period of nearly twenty years is to have had a twenty-years-long privilege. Few may have pierced his peculiar reserve, but to those who did there was a very different character beneath that which was suggested on the surface. He was at his best with children in the open. A lover of wild things he had the rare gift of opening the eyes of others to the beauty of the world around, and knew where Pan hid his treasures from the curious. But with adults he was peculiarly diffident, and one might have easily missed that kindness, of which many a poor patient will tell to-day with tears, and that sterling character of which his intimates had ever and anon fresh revelations. Gough, or "B. B." as he will ever be to his old Guy's friends, could never force himself forward, and when he volunteered for the war no one can gauge what it cost him. He was ever governed by high principles, and loyalty to the loftiest motives always found its response in his life and conduct. When he heard the call of duty he never wavered, but gave his all cheerfully. I was privileged to see him on his way through a south coast town to the front, and though he said nothing of his distaste for the employment of war, I could appreciate to some extent the sacrifice of himself it had been to offer for war service. The

sacrifice offered has been accepted to the full. The old days at Guy's and the more recent days in his country practice in the picturesque Mendip village of Compton Martin are over, and I feel that one of the beloved characters of Life's Book has gone out of the story and that much of the charm has gone too.

SURGEON-GENERAL CHARLES EDWIN McVITTIE, Madras Medical Service (retired), died at Exmouth on February 17th. He took the L.R.C.S.I. in 1865, and the Fellowship in 1874, and the L.R.C.P. Edin. in 1866. He entered the I.M.S. as assistant surgeon on March 31st, 1866, became surgeon on July 1st, 1873, surgeon-major on March 31st, 1878, deputy surgeon-general on March 7th, 1891, and surgeon-general on April 1st, 1895, retiring on April 1st, 1900. A good service pension was conferred upon him from May 17th, 1894, and on March 23rd, 1898, he was appointed honorary physician to the Queen. He served in Afghanistan in 1880, receiving the medal, and in Burma in 1886-7, when he was mentioned in dispatches, in G.G.O. No. 434 of 1887, and received the medal with two clasps.

DEPUTY SURGEON-GENERAL EUGENE FRANCIS O'LEARY, R.A.M.C. (retired), died at Sidmouth on February 20th, aged 80. He took the diploma of M.R.C.S. in 1856, and the degree of M.D.R.U.I. in 1870. He entered the army as assistant surgeon on February 9th, 1856, became surgeon on February 9th, 1868, and surgeon-major on March 1st, 1873, retiring as brigade surgeon, with the honorary rank of deputy surgeon-general, on December 12th, 1883. He served in the Egyptian war of 1882, and received the medal and the Khedive's bronze star.

BRIGADE SURGEON EDWARD ACTON GIBBON, of Sledagh, co. Wexford, High Sheriff of Wexford, died there on February 15th, aged 80. He was educated in Dublin, and took the diplomas of L.R.C.S.I. in 1858 and L.K.Q.C.P.I. in 1860. Entering the army as assistant surgeon on September 1st, 1858, he became surgeon on September 1st, 1870, and surgeon-major on March 1st, 1873, and retired with a step of honorary rank on March 12th, 1880.

LIEUTENANT-COLONEL ALFRED JOHN BELEMORE, R.A.M.C. (retired), died at Brighton on February 4th, aged 76. He was educated at St. Mary's, took the diplomas of M.R.C.S. and L.S.A. in 1861, and joined the army as assistant surgeon on April 16th, 1862, becoming surgeon on March 1st, 1873, and surgeon-major on April 16th, 1874, and retiring on March 22nd, 1888. The *Army List* assigns him no war service.

SURGEON-MAJOR ARTHUR SANDERSON, R.A.M.C. (retired), died at Joanville, Jersey, on January 23rd, aged 81. He took the diploma of M.R.C.S. in 1857, entered the army as assistant surgeon on January 12th, 1859, became surgeon on January 12th, 1871, and surgeon-major on March 1st, 1873, retiring on March 28th, 1890. The *Army List* assigns him no war service.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. A. Morgan Vance, of Louisville, Kentucky, a well-known orthopaedic surgeon, aged 61; Dr. Pietro Da Venezia, for forty years physician-in-chief to the Ospedale Civile of Venice, aged 80; and Dr. R. A. Witthaus, for many years professor of chemistry at the Cornell Medical College, editor in conjunction with Becker of a treatise on medical jurisprudence, and author of numerous contributions on toxicology, on which he was a recognized authority, aged 69.

The Services.

TERRITORIAL FORCE.

MAJOR M. J. MAHONEY, M.D., attached to the King's (Liverpool Regiment), has been awarded the Territorial Decoration.

EXCHANGES DESIRED.

CAPTAIN T. CAMERON HOUTON, R.A.M.C. (T.), 21st Lowland Mounted Brigade Field Ambulance, Cupar, Fife, Scotland, gazetted Captain October 2nd, 1915, wishes to exchange with a medical officer on active service, in any capacity.

Northern Command.—M.O. wishes to exchange; preferably for Cannock Chase district.—Address No. 1150, BRITISH MEDICAL JOURNAL Office, 423, Strand, W.C.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Radcliffe Travelling Fellowship.

The electors have elected George E. Beaumont, B.A., University College, to a Travelling Fellowship on the Foundation of Dr. John Radcliffe.

UNIVERSITY OF CAMBRIDGE.

At a congregation on March 10th a grace was approved to the effect that, notwithstanding the regulations prohibiting any degree other than an honorary degree being conferred out of term, the vice-chancellor should be authorized to admit candidates to degrees in medicine and surgery at a congregation during the long vacation. This arrangement was made because, owing to the late date at which medical examinations in the Easter term are held, it was not possible for the class lists to be issued before the last congregation in Easter term, and the successful candidates would be placed at a serious disadvantage if unable to proceed to their degrees until Michaelmas term.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on February 23rd.

Mr. Thomas Yeates was recognized as a teacher of anatomy at the Middlesex Hospital Medical School and his name added to the Board of Intermediate Medical Studies and of Studies in Human Anatomy and Morphology.

The subject of the essay for the Paul Philip Reitlinger prize in 1917 is "The comparative treatment of native races in the British Empire."

Special War Regulations for Medical Students.

—It was resolved:

That, from the present time until a date after the termination of the war to be fixed later by the Senate, Internal Students who have been debarred from presenting themselves for examinations for medical degrees by service under the War Office or Admiralty, or by hospital service in connexion with the war, or by other approved service in connexion with national defence, be (i) permitted to enter at the First Examination for Medical Degrees in either (a) inorganic chemistry and physics, or (b) general biology, provided that the authorities of the schools to which they are attached shall recommend that they be permitted so to enter; (ii) credited with any subject in which they pass at the First Examination for Medical Degrees or Second Examination for Medical Degrees, Part II; (iii) permitted, if they fail in Forensic Medicine only in Group I of the Third Examination for Medical Degrees, to present themselves for re-examination in that subject only in order to complete the examination in Group I; provided that they comply with the regulations in all other respects.

UNIVERSITY OF BRISTOL.

The following candidates have been approved at the examination indicated:

SECOND M.B., CH.B.—B. A. Astley-Weston, Elizabeth Casson, R. F. White.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary council was held on March 9th, when Sir William Watson Cheyne, president, was in the chair.

Dental Surgery.

Diplomas in dental surgery were granted to twenty-eight candidates found qualified for the licence.

A report from the Board of Examiners in Dental Surgery was adopted by the council, and it was decided to inform the General Medical Council, with further reference to its letter of March 11th, 1915, that the council of the Royal College of Surgeons of England think that the present curriculum for dental students might be revised in accordance with the recommendations of the Board of Examiners in Dental Surgery without impairing the sufficiency of the guarantees for efficient practice contemplated by the Dentists Act.

General Medical Council.

Sir Henry Morris was re-elected the representative of the College in the General Medical Council.

Bradshaw Lecture.

Mr. Charters J. Symonds was elected Bradshaw lecturer for the ensuing collegiate year.

ON February 24th Mr. W. D. Spanton, consulting surgeon to the North Staffordshire Infirmary, presided at Stoke over the jubilee meeting of the North Staffordshire Field Club. It was founded in Mr. Spanton's rooms in the old North Staffordshire Infirmary at Etruria in April, 1865, and he was one of the first honorary secretaries. From his review of the fifty years' work of the club it appears that it has an archaeological section, with sketching and photographic sections which preserve records of buildings in the district, and sections on geology, entomology, zoology, botany, microscopy, and meteorology. It has a medal and a library founded in honour of past secretaries, and also a natural history museum, now under the aegis of the county borough authorities. A vote of thanks to Mr. Spanton, moved by two old members of the club, was cordially adopted.

Medical News.

DR. FRANCIS JOHN HARVEY BATEMAN, of Heath End, Blackheath, has been appointed a justice of the peace for the county of London.

A VIENNA manufacturer has given £20,000 for the foundation of an institute for the study of the proper food (*Volksernährung*) by correlating the results of research in organic chemistry, biology, and physiology.

DR. D. D. MAIN of the Church Missionary Society Hospital, Hankow, and Dr. Sidney G. Kirkby-Gomes, medical officer of the Peking-Mukden Railway, have received the King's permission to wear the decoration of the fourth and fifth class of the Order of the Excellent Crop, conferred upon them by the President of the Chinese Republic.

THE King has granted permission to the following members of the profession to wear the decorations of the class of the Order of the Nile indicated, conferred upon them by the Sultan of Egypt in recognition of valuable services rendered:—*Third Class*: Dr. J. B. Christopherson of the Sudan Civil Service. *Fourth Class*: Captain A. G. Cummins, M.B., R.A.M.C., and Dr. V. S. Hodson, M.V.O.

AT a recent massage examination held by the Incorporated Society of Trained Masseuses there were 201 candidates, of whom 131 passed, six with distinction. The list was headed by a blind student, Mr. P. L. Way. Among the other successful candidates were five blind students, one a surgeon, who were trained at the National Institute for the Blind, 246, Great Portland Street, London, W. In addition six blind soldiers passed the first part of the examination.

AT the annual meeting of the Cancer Hospital on March 10th, the chairman, Lord Northbrook, said that at the outbreak of the war an offer of the use of the hospitals, exceptionally well-equipped electrical and x-ray departments, and 50 beds had been accepted by the War Office. During the past year 57 soldiers had been admitted to the wards and 135 military patients had received treatment in the electrical and radio-therapeutic department; a large percentage of the cases treated were restored to health and to active service.

PROFESSOR ETTORRE MARCHIAFAVA has been appointed to the chair of clinical medicine left vacant by the death of Professor Guido Baccelli. His name is best known by his work on malaria, but he has also made valuable researches on tuberculous and syphilitic arteritis, glomerulo-nephritis, and epidemic cerebro-spinal meningitis. He is a Grand Officer of the Crown of Italy, a Senator of the Kingdom, and President of the Società Lancisiana degli Ospedali di Roma, and a member of the Superior Council of Public Instruction.

UNDER the title of "Prophylactic Institute" an association has been formed in Paris whose object is to conduct a campaign for the gradual extinction of syphilis. Besides the direct treatment of patients, it will undertake scientific researches, and bring continuous action to bear on the administrative authorities. Among the members are Dr. Roux, Director of the Pasteur Institute, Dr. Landouzy, Dean of the Paris Faculty of Medicine, M. Painlevé, Minister of Instruction and of Inventions affecting National Defence, M. Brioux, author of *Les Avariés*, and other well known men. Mr. F. Jay Gould has sent a cheque for 250,000 francs (£50,000) to the Foundation Committee of the new institute.

AT the annual meeting of the Association for Promoting the Training and Supply of Midwives, held on March 14th, an address was given by Dr. E. W. Hope, M.O.H. Liverpool, on the subject of midwives and their relations with public health bodies. The comparative poverty of industrial Liverpool, he said, was reflected in the fact that out of 23,000 births last year, 17,000 were attended by midwives. He regarded it as of great importance to the community, particularly in respect to the provision of antenatal care, that the sympathies of the midwives should be enlisted officially. In Liverpool the midwives had a local association, and the authorities were thus able readily to get into touch with them, and at the same time encourage post-graduate study, of which the midwives themselves arranged the courses, given at the University. The midwives were on friendly official relationships with the Health Committee, and were regarded almost as part of the sanitary staff. Dr. Hope suggested a more careful adjustment of functions as between midwives and district nurses, and also the inclusion of four months' midwifery training in the education of the ordinary nurse.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

NEED FOR RESIDENT SURGICAL OFFICERS AT HOSPITALS.

THE Central Medical War Committee invites applications from gentlemen of good hospital surgical experience, who, being over age or otherwise disqualified for service in the R.A.M.C., would yet be willing, if the necessity arose, to take appointments as resident surgical officers in hospitals. This appeal is not intended to interfere with the ordinary announcements of vacancies for such posts, but the Central Medical War Committee would like to have in reserve a supply of experienced surgeons who would, if necessary, be prepared to fill such appointments for a time. Applications should be sent to the Secretaries, Central Medical War Committee, 429, Strand, London, W.C.

CHEER FOR THE NERVE-SHAKEN.

DR. S. E. WHITE (London, W.) writes: In an address reported in the BRITISH MEDICAL JOURNAL of January 8th, 1916, Dr. Bedford Pierce, of York, dealing with the possible ways of aiding recovery from recent nerve disturbance or transient loss of balance, expressed the opinion that there is legal difficulty about treating these cases otherwise than by bringing them under lunacy control, and that, consequently, legislation will be necessary to do away with that section (315) of the Lunacy Act, which will not allow restraint to be exercised without the individual being certified and his case thoroughly investigated.

But is detention always required? Are there not a great many cases which, if taken early enough, would gladly go of their own accord to some home, hospital, or sanatorium for appropriate medical care and more hopeful and health-giving surroundings, were such attainable? Dr. Pierce himself points out—apparently unconscious of any inconsistency—how very successful have been the results obtained at the present time in two infirmary wards in Glasgow, and also in a branch of the Lady Chichester Hospital at Brighton. Both of these are on a voluntary footing, and carried on apart from lunacy. Sir T. Clouston's proposal for a Mental Ward in the Edinburgh Royal Infirmary was not frustrated by any legal difficulty, but only by a majority of one vote on the Infirmary Board.

That insanity is increasing is shown very clearly by the figures for the last eight years given in the BRITISH MEDICAL JOURNAL of January 15th, 1916, especially those relating to the increased frequency of first attacks. A diminished recovery-rate is also noted. The best hope for the future lies in a cheering atmosphere, such as will steady, quiet, and help the troubled mind and give it reassurance, rather than in condemning the nerve-shaken to seclusion and repression. A movement was on foot just before the war, supported by half the House of Commons, to provide such preventive hospitals under the councils. Were these hospitals in existence now, they would be a great boon for the care and cure of our soldiers invalided through nerve shock.

There are numbers of nerve-shaken soldiers among the wounded who get well in a short time in the base hospitals, thus proving that it is quite unnecessary to place the unwounded, when uncertain, in asylums. What they need is rest and sleep and encouragement, with ordinary medical care, interest, occupation, and recreation when convalescent. Everything that tends to remove depression and to quiet anxiety is a clear gain, and the men are very conscious of where they are and the prospect before them.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances, by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

A CASE OF BILATERAL MOTOR APRAXIA WITH DISTURBANCE OF VISUAL ORIENTATION.

BY

S. SMITH, M.B., B.S.LOND.,
CAPTAIN (TEMPORARY) R.A.M.C.,

AND

GORDON HOLMES, M.D., F.R.C.P.,
LIEUTENANT-COLONEL (TEMPORARY) R.A.M.C.

It has been only within the last few years that the motor disturbance known as "apraxia" has claimed much attention, or been fully investigated, and even yet very few well-marked instances of the condition have been described in English literature. In fact, it is mainly through the careful summary of the work of Continental authors, published seven years ago by Dr. S. A. K. Wilson, that apraxia is known to English readers.

Apraxia is a complicated condition, but in its simplest terms it consists in inability to combine simple movements into complete purposive acts; in other words, it is a condition in which a patient in whom the power of voluntary movement is intact, or at least not seriously affected by palsy, ataxia, or sensory loss, is yet unable to perform certain actions, or is incapable of employing objects—as a knife or a key—correctly, even though he is aware what is required of him, and though he recognizes the use and the nature of the object. Liepmann, to whom our knowledge of the condition is largely due, has defined motor apraxia as incapacity for subjectively purposive movements of the limbs, with conservation of the power of movement.

Apraxia may be of different degrees of severity, and may affect the limbs of only one or of both sides; its only manifestation may be the inability to protrude the tongue, to which Hughlings-Jackson originally drew attention in hemiplegic patients, or the patient may fail in most actions he is requested to attempt. Usually, however, he succeeds in some acts and fails in others—as a rule, in the most complicated and less familiar.

Many factors may contribute to this complex functional disturbance, especially mental impairment with affection of memory and attention, sensory loss, and agnosia or inability to recognize objects; but in the case described here the intellectual state was moderately good, there was no affection of sensation, and no form of agnosia. Vision, it is true, was affected, but its disturbance obviously stood in no causal relation to the apraxia.

The patient, Pte. M., aged 27, was admitted to a base hospital on November 2nd, 1914, with the history of having been wounded in the head by a shrapnel bullet some days previously. On admission he was in a dull and confused state; he was unable to remember his number or regiment, how he was wounded, and what happened to him during the several days that elapsed between the infliction of the wound and his arrival at the base. There was no paralysis, and the range and the power of the movements of all his limbs were normal; there was no obvious ataxia. The right knee-jerk was, however, brisker than the left, and the plantar response on this side was extensor. Tactile and painful stimuli were appreciated naturally and localized correctly everywhere, and there was apparently no loss in his sense of position. There was no optic neuritis.

The wound of entry was a small puncture 23 cm. behind the nasion (nasion toinion = 34 cm.) and 7 cm. to the right of the middle line; there was no exit wound, but a round shrapnel bullet could be felt under the scalp 4 cm. above and 4 cm. behind the upper margin of the attachment of the left pinna. An x-ray examination revealed a small gap in the skull under the wound of entry and several fragments of bone deep in the brain substance along a track leading from it. The bullet had apparently just broken through the skull in the left temporal region, and was removed, together with several fragments of bone, by Lieutenant Colonel Sargent a few days later. It was a spherical lead ball 12 mm. in diameter. It was dropped into sterile broth, but produced no growth. A clean circular opening, only slightly larger than the missile, was found in the squamous bone. The entrance

wound was not touched till several weeks later, when a few fragments of bone, which had probably been extruded from the brain, were removed from dense fibrous tissue at the bottom of a shallow sinus.

His condition improved rapidly after his admission to hospital; no weakness or paralysis developed, the reflexes became normal, and all forms of sensation remained unaffected. His hearing was also normal, but there was a complicated disturbance of vision which will be described in detail later. He rapidly regained almost the entire use of his intellectual faculties; he had been apparently an intelligent man, had been educated at a first-class school and trained as an engineer; before enlistment he was employed as a draughtsman. His memory for the past was evidently fair, but there was a blank, which gradually diminished, for events that occurred during a considerable period before the infliction of the wound. On the other hand, his retentiveness, especially to visual impressions, was much impaired. His general attention was always fair, though at first he tended to tire easily. At no time, however, during the three months he was under observation could his behaviour and conduct be described as normal: it rather resembled that of an intelligent child, and he was in fact always treated by his fellow patients and by the nurses as an interesting child would be. He was always too facile, laughed unnecessarily and often inappropriately; and on one occasion, when another patient near him died, he burst into tears and asked to be moved into another ward. He was always extremely good tempered and never moodish. One striking feature was the fact that he rarely showed any signs of irritation or natural annoyance when he failed to perform simple actions on request or spontaneously.

There was considerable disturbance of speech when he was first admitted, but it became gradually less; in the first place he stuttered, but according to his own statement he was subject to this in childhood, and, apart from this, he had no obvious difficulty in uttering words. He could understand speech and even complicated orders fully, or failed to do so only when his power of retaining the whole sentence was at fault. He always comprehended, for instance, and reacted intelligently to any joke made at his bedside. He had, however, some difficulty in calling up words, especially names, but even then succeeded in expressing himself fully by the substitution of a word or of an explanatory phrase. He never used wrong words.

He was from the first able to read and comprehend short sentences, but had great difficulty in following consecutive words and lines owing to his visual trouble; during the whole time he was under observation he had, however, considerable difficulty in reading individual letters aloud. He was quite unable to write even single letters, and on attempting it only made an unintelligible scrawl—most often a rough circle—but as he was equally incapable of drawing a line or any simple object, although he was a draughtsman by profession, this inability was obviously due to his apraxia rather than to a specific agraphia. Between two and three months after the infliction of the wound, when most of these observations were recorded, his speech defect was almost negligible.

In spite of the fact that there was no weakness, ataxia, or sensory disturbance in any of his limbs, he showed from the first day he was in hospital a peculiar motor disability, which consisted essentially in an inability to perform certain even simple purposive actions and to use objects and instruments which were quite familiar to him and which he recognized correctly. At first, for instance, he had even difficulty in feeding himself, in performing movements to order, and in using even the simplest tools, as a pencil or knife, but with time this inability gradually diminished, apparently largely owing to constant practice and steady application, for he certainly relearned first those actions of which he had most need, as lighting a cigarette.

The nature of this disability can be most easily conveyed by describing his attempts to execute actions of various kinds. Here, however, it is advisable to emphasize again that he always had a clear idea of what he was required to do, and that he never showed any signs of agnosia, or inability to recognize the use and nature of objects which he perceived either by vision or by touch. Further, he was never satisfied with the execution of a wrong action or with the misuse of an instrument, as a patient with

aphasia, agnosia, or "general mental impairment may be. On the other hand, he was always anxious to explain his mistakes and failures, generally saying, "I have forgotten how to do it," or "That is something like what you wanted me to do, but it is not quite right; I can't remember exactly."

An attempt to analyse his difficulties by further introspection yielded no reliable facts.

The motor disability was equally pronounced in his two hands, and involved the movements of his legs too; it was usually more prominent when the action required the use of two hands than in those which he could perform with one alone; when given, for instance, a knife and fork he always focussed his attention on and directed his efforts to the one first, and only after he was satisfied with the result attempted to grasp the other or use it appropriately. His disability could be excellently illustrated by handing him a pencil and asking him to draw a line, any simple object, or form a letter; at first he had great difficulty in taking hold of the pencil correctly, and when he suc-

ceeded, or after he had learnt to do so, he would bring its point slowly to the paper and then hesitate as though perplexed as to how to use it. If urged to complete the drawing or letter he would suddenly make an irregular scrawl, which frequently resembled an O or C, and if then asked what he had drawn, would smile and remark, "No, that's not what I wanted to do, that is like an O (or C)." The result was the same whether he was asked to write a letter or draw a straight line or a pipe, yet he always recognized these figures when drawn and shown to him; on one occasion, when he had formed a circle in his attempt to sketch a pipe, he pointed out that it was like the opening of the bowl of the pipe, but it was not what he intended to draw. He succeeded no better in his attempts to copy simple linear figures.

The following table illustrates his efforts to perform certain actions about two months after the infliction of the wound; the actions required of him are given in the left column, his attempts to execute them in the right.

1. Actions to Order.

A. Put out your tongue	Well performed (formerly unable to do this, showed teeth, and grinned when this order given).
B. Cough	Well performed.
C. Smell	No movement at first; succeeds when piece of soap put in front of him; when this is removed, fails.
D. Yawn	Opens mouth, makes whistling movements.
E. Whistle	Opens mouth, puts out tongue.
F. Put right hand on top of head	At first brings hand to chin; then to nose; then holds it in front of him, says, "This is my right hand," and slowly brings to top of head.
G. Put left hand on top of head	Identical with last.
H. Put right thumb into mouth	Identifies thumb, then puts forefinger into mouth; recognizes mistake. Says, "No, that's my thumb"—holding thumb with left hand; eventually puts left thumb into mouth.
I. Turn eyes to right	Looks straight in front of him, then looks to left, finally turns eyes to right.
J. "Eyes right" (uttered sharply as a military order).	Well and quickly performed (at first had no more success with this than last order).
K. "Salute"	Brings hand smartly to forehead giving correct military salute. (Has been able to perform this military act almost from the day of admission.)

2. Ability to Recognize and Use Various Objects when Shown Them.

A. Shown a key	Names correctly; describes use "to put in lock," fumbles with key for nearly a minute, holds in many attitudes, then, holding by ring at last makes correct movement with hand.
B. Use of knife and fork	Fails to get either knife or fork correctly into hand, grasps in various positions; first puts fork in left hand, knife in right, then changes about; even when they are placed correctly in hands fails to make correct movements.
C. Unbutton coat	Slow and clumsy, but succeeds; tendency to "tear out" button.
D. Button coat	Correct with right and left hands.
E. Shuffle a pack of cards	Takes hold of cards aimlessly, one or two at a time; makes no attempt to shuffle.
F. "Shoulder arms," when given piece of wood to represent rifle.	Takes "rifle" first in one hand, then in the other; holds against right shoulder, then to left, performing various movements, all incorrect, with unengaged hand; makes no intelligent attempt even when shown correct method by observer.
G. Given a book upside down; told to read from it.	Says, "Oh, this is upside down"; endeavours to rectify error, turns over pages, holds book on end, looks along it, fumbles with pages; says, "No; I can't do it." When book put right way up by observer and given him, says, "Yes; that's right," and proceeds to read.
H. Open matchbox and remove three matches.	This correctly performed after some fumbling and hesitation. (He was quite unable to do this for some days after admission, but, being an ardent smoker, has since had plenty of practice.)
I. Light cigarette in his own mouth with one of the matches.	Some difficulty in finding which is right portion of box to strike on; first strikes wrong end of match; commences by lighting cigarette at about its middle, then very nearly burns his moustache, finally succeeds, and puffs away contentedly.
J. Replace unlighted matches in box	Experiences much difficulty; first attempts to stuff them into unopened box, then opens box holding it upside down, at last finds interior of box and replaces matches in a very clumsy fashion.

3. Representation of Use of Objects Without Being Shown Them.

A. Movement of key in lock	Performs well, rotates hand correctly.
B. Shake hands	Holds right hand out, fingers extended, rotates arm (as in turning key in lock).
C. Given a bowl, make movement of eating from it with an imaginary spoon.	Quite unable to perform. (Succeeds if given a spoon with bowl.)
D. Make movement of brushing teeth.	Catches hold of chin, then says, "No; I had an idea, but I have lost it." Makes various incorrect attempts, and says, "No; it's no use."
E. Make movement of turning handle of a barrel organ.	Holds out right hand as in B, rotates (again as in turning key in lock).
F. Make movements of washing hands.	Succeeds only if a piece of soap and water in basin are given him.

4. Imitation of Certain Movements made by Observer.

A. Make a fist	Correct right and left hands.
B. Hold hands in prayer attitude	Brings right hand to right side of face, says, "No; that's wrong"; recognizes attitude when shown him by observer, says, "Yes; it's in the picture you see everywhere"; then performs it correctly.
B. Repeated	Caught hold of chin, then extended both hands in front of him, saying, "I thought I was going to do it."
C. Hold piece of wood horizontally with either hand.	Takes object, fumbles with it for a time, then places it vertically; unsatisfied with this position, and eventually gives up the attempt.
D. Catch nose with hands; first right, then left.	Correct.
E. Put right finger in ear	Hesitates; first puts hand on top of head, then correct.

5. Performance of Various Expressional Movements.

A. Smiling, looking cross, looking sad, surprised, etc.	Normally performed, both to order and also in reaction to surroundings.
---	-----	-----	---

6. *Conventional or Actions and Activities of Ordinary Life.*

- A. Throw a kiss Correct.
 B. Beckon Waves whole hand in an indefinite manner. Says, "No, that's wrong; I can't get it right."
 C. Dressing Fails completely to put on pyjama jacket. Likewise fails with trousers, putting both legs into one trouser leg, unable to extricate himself without assistance, although he makes violent efforts.

7. *Performance of Certain Reflexive Movements.*

- A. When ear is tickled with a feather, patient puts up hand to remove the stimulus automatically, though when ordered to put finger in ear is unable to do so.
 B. If a hair is pulled, or if he is pinched, he brings his other hand readily to the spot stimulated, and withdraws the part stimulated.

Lower Limbs.

When his lower limbs were investigated, a condition very similar to that which affected his arms was found—that is, he had difficulty in performing purposive actions to order, imitating those made by the observer, and in employing his legs in more complex acts, as in putting on his trousers. When told to bring his right heel to his left knee, for instance, he merely crossed his feet; and when asked to put on a sock, was unable to do so, not only because of the apraxia of his arms, but mainly because he failed to hold his foot in a proper position. Similarly, on one occasion when, after walking about the ward, he was told to sit on his bed, he placed his hands on it, then turned his back away from the bed, and, after some hesitation, began to sit down in this direction.

REMARKS.

These descriptions give an idea of his condition as it was about two months after the infliction of the wound. During the following month a certain amount of improvement occurred, especially in performance of actions in which he had had practice—as in getting his smoking materials together and lighting a cigarette. Further, it was found that he could be taught by daily practice to perform actions in which he could not at first succeed; he became able to turn a book which was given to him upside down into the correct position when he was made to do so several days in succession.

The tests recorded above show that there was no tendency to misuse or mistake objects, and no trace of agnosia; further, it was evident that he was never satisfied with his mistakes or with one action when another was required of him. Although he frequently explained his failures by saying, "I have forgotten how to do it," it was evident that they were not due to lack of attention or loss of memory, for his general attention was always fairly good, and, apart from a deficient retentiveness of visual impressions, his memory was not seriously impaired.

There was at no time any trace of tonic perseveration or that difficulty in relaxing muscles that he had contracted voluntarily, which has been often associated with apraxia; and it was only in the early stages of his illness that he showed any tendency to repeat actions which he had just performed when requested to do something else (clonic perseveration).

VISUAL DISTURBANCE.

When the patient first came under observation a disturbance of vision was noticed, but its nature could not be properly investigated till his general condition had improved. The most striking feature was his difficulty in looking straight at the observer's face or at any object held in front of him; when asked to do so, he generally stared open-eyed in a wrong direction and then moved his eyes about in an irregular manner, most commonly towards the ceiling, saying, "Sometimes I can see quite well, but often I cannot see what I want to look at." On the whole he seemed to see better the less effort he made. Further, even when he could see and recognize an object, he usually failed to take hold of it directly.

At present, three months after the infliction of the wound, these troubles persist, though they are less pronounced than they were. The optic discs are normal; his central vision is now $\frac{5}{6}$ in each eye, and he can recognize the movement of fingers in all parts of each half of his visual fields. Perimetric examination is not easy owing to his difficulty in keeping his eye directed on the fixation point; but repeated observations have shown he can recognize a white object 10 mm. square to the normal peripheral limits in both eyes. There is, however, some

amblyopia in both lower right quadrants, which reaches to within 10 degrees of the fixation point. In this amblyopic area he frequently says, "There is something moving, but it is not plain, and I don't know where it actually is." No defect in visual acuity can be discovered in the left halves of the visual fields, and the fields for red and green are normal in extent to both sides of the fixation point.

Although there was no ocular palsy, for several weeks after his injury he was frequently unable to move his eyes to order in any given direction, even though he understood fully what was required of him, and still he often makes mistakes or succeeds only after several attempts; when on one occasion he was asked to look upward toward the ceiling as he was sitting erect, he pointed correctly to it with his hand, but moved his eyes first to the right, then to the left, and finally downwards. His eyes are, however, always turned accurately towards an unexpected noise made to one side of him, and he generally succeeds in obeying the military command of "Eyes right" or "Eyes left" when either is suddenly given to him.

He is still unable to follow accurately with his eyes a finger or any other object moved in any direction; they generally remain for a moment directed towards the position in which he originally fixed it, and may either fail to follow it at all, or they may be later suddenly jerked towards the direction in which it was moved. Similarly he fails to keep his eyes fixed on a spot, as on the observer's eyes, when his head is passively rotated to either side.

The difficulty in fixing or bringing into central vision objects in front of him is passing off, but he frequently fails still to look directly into the observer's eyes or at any object when asked to do so; often he merely opens his eyes, stares in a wrong direction, and then swings his eyes irregularly about in search of it. Even when there can be no doubt that he knows the position of the object in space at which he should look, as his own hand, for instance, he often fails to bring his eyes directly to it. The tendency for his eyes to deviate from the object he has fixed is now less than it was.

Further, there is frequently no reflex blinking, withdrawal of the head or other general reaction when a hand or other object is suddenly swung towards his eyes, either from in front or from either side, or to any other threatening action on the part of the observer. And when a light is suddenly turned on to one side he does not, as a rule, turn his eyes to it with the accuracy and promptitude of a normal person.

He still does not succeed in taking hold of an object held in front of him and in his line of vision with precision and accuracy. This defect is more clearly seen when he is asked to touch a spot on which his eyes are directed; several records were taken by asking him to bring his finger to a black dot on a sheet of paper held in various planes of space in front of him, and it was found that the error was equally great in all directions. This defect cannot be attributed to ataxia of his limbs—that is, to disharmony in the range and time of the components of the movement, as there is no evidence of this as he handles or attempts to use objects; nor can it be wholly due to the motor disability described above, as he can bring his finger accurately to the tip of his nose, even when his eyes are closed. Further, there is no demonstrable loss in the sense of position or of passive movement to which "sensory ataxia" could be due. Despite the inaccuracy and awkwardness of his movements he can, however, always succeed in reaching any object which is at the moment in central vision. On one occasion, when he was not aware he was under observation, he wished to get a box of matches from his locker in order to light a cigarette; he sat up in bed, turned his head and eyes

towards the locker, stared vacantly at one spot for a moment, then slowly and deliberately moved his eyes into other directions, until, after several seconds, the matchbox came into his central vision; then he put his hand out to take hold of it, but did not succeed in doing so accurately on the first attempt.

He does not present any trace of visual agnosia—that is, an inability to recognize and distinguish by their visible characters objects he can see. From the first, too, he recognized ordinary symbols, as the plus, subtraction, and the multiplication signs, an arrow pointing direction, etc. That he can recognize letters and read has been already pointed out. Further, he recognized at once the well-known visual illusion of the truncated pyramid, saying, "That's a box; it changes according as your eyes catch it, sometimes I can see it open, sometimes the other way."

His visual memory, too, is at least not seriously affected; he can from memory describe the form of familiar objects—as a pipe; give a minute description of his father, and tell how he would reach his bedroom at home. He is evidently a strong visualist, and speaks of having "a good picture" of incidents which occurred while he was in the trenches, as of a German attack by fire. His colour memory is apparently also intact; he can remember the colours of the football shirts worn by a local team, and describes the sky as "blue as a rule, with clouds of different colour, and it is often red at sunset, especially in stormy weather."

On the other hand, his visual retentiveness is very defective; when he is shown in succession four objects which he can recognize and name, he is, as a rule, unable to name them again or describe them in correct order after an interval of thirty seconds; and after the same period he is unable to recollect the number or arrangement of four or five dots which he had seen on a sheet of paper. He is much more retentive to auditory impressions, as words or sentences repeated to him.

Another prominent symptom is his inability to localize, or at least recognize correctly, the relative positions of objects placed in front of him. He has always been much confused as to which is right or left, and even after daily testing he has remained uncertain which is his right and which his left hand, and his difficulty in describing whether one object is to the right or to the left of another is consequently not surprising; but it was found that when he looked at two objects he was uncertain whether two similar objects which were immediately uncovered were in the same relative positions, or if their positions had been changed when he closed his eyes for a moment. This held whether the test objects were side by side, one above the other, or one nearer to him. (These tests were carried out by silver and copper coins of the same size, and by squares of green and white paper.) The most remarkable errors were made when he was asked to say which of two objects was the nearer to him; even when they were separated by 10 to 15 cm., at a distance of half a metre from his eyes he made many mistakes; the explanation he offered spontaneously was, "I can only look at one at a time"; when his finger was moved from one to the other he could, however, recognize their relative positions at once.

Similarly, he often fails to distinguish the difference in length of two lines, even when it is considerable, and frequently calls the shorter the longer, or vice versa, though their lengths may be in the proportion of two to three. This is especially so when they are not drawn parallel and close to one another. An attempt was made to determine whether this failure is dependent on a defect in the execution of, or on a disturbance of the proprioceptive impulses initiated by, his ocular movements, by comparing his replies when he was allowed to look at the lines for some time and range his central vision over them, with those he gave when the lines were exposed for only a moment, but his difficulty in fixation made reliable conclusions impossible. But, though he is unable to estimate the relative lengths of two lines, he can always recognize accurately and without delay whether a rectangular quadrilateral figure is a square or not; this is apparently due to the fact that he sees the figure as a whole and recognizes its shape at once, as he can a drawing or an illustration, while to compare the lengths of two lines he must move his eyes from one to the other.

When an object is held up to one side of the point he is at the moment fixing, he always fails to take hold of it or even point in its direction if he does not look at it directly; if, for instance, the observer's arms are outstretched from his side, and the patient is asked to point to the moving fingers of one or other hand he usually only brings his own hand to the observer's face or shoulder. As there is neither ataxia or serious sensory disturbance in his arms, this failure can be due only to his inability to orientate and localize correctly objects in the extra-central portions of his fields of vision; in fact he states not infrequently that though he can see the object he is not sure where it is. This was clearly demonstrated during examination with the perimeter; he frequently said he was only aware that "something white was moving somewhere" as the test object was brought towards the fixation point, and frequently made gross errors when he attempted to point to or describe its position; on one occasion, for instance, he described it in the left lower quadrant when the object was in the right upper quadrant.

There is obviously, then, a loss of the local signature of visual impressions identical with that loss which as a result of cerebral lesions often leads to disturbance in the localization of tactile stimuli.

He frequently fails to recognize moving objects by extra-central vision, in portions of the visual fields in which he is certainly not blind, especially when two are presented simultaneously to him, one to each side of the fixation point, as the observer's fingers for instance. The proportion of such stimuli which he misses is variable, and increases as he tires or when his attention flags. A similar inability to recognize, with the constancy that a normal person can, the presence of objects outside central vision is occasionally seen as a one-sided phenomenon with lesions of the post-central portion of the opposite cerebral hemisphere.

That objects outside his central vision do not readily excite attention is seen in many other tests too. When asked to read, for instance, he was at first frequently satisfied to pick out a few individual words from a page, and he still has difficulty in following the lines in the normal manner. Now he occasionally takes up the daily paper, which he can read intelligently, though only slowly and with difficulty, due, he explains, to the fact, "I start to read a column, but soon skip some lines, or I may get on to another column." It is remarkable that even when only one of a row of letters which he was asked to read was exposed to him, he frequently failed to fix it, saying, "I'm not looking at it now, I have lost it"; and that immediately afterwards he read correctly and with scarcely any hesitation the following title, which contained words certainly unfamiliar to him, "Histological and Experimental Observations on the Destruction of Tumour Cells in the Blood Vessels."

He also makes very poor attempts at exploring with his eyes any large surface presented to him; if, for instance, he is shown the page of a journal on which there are a few widely-separated illustrations, he often says there is only the one on which his eyes first fall, and rarely succeeds in detecting them all. Similarly, when he is asked to count or to point to four or five coins placed irregularly and at some distance apart on a board in front of him, he is generally content with indicating one or two, and makes no attempt to run his eyes over the whole surface to make sure that those only are present which he had seen at the first glance. This failure is obviously not due only to the right-sided hemianopia, for he fails as often to pick out objects to the left as to the right of the point to which his eyes are directed; it seems, in fact, that his attention to visual impressions tends to be arrested or occupied by any object that is at the moment in central vision. If, on the other hand, he is asked to count coins or other objects arranged in a close series in front of him he usually starts at any part of the series to count to right or left, but soon becomes confused and begins to enumerate again those which he had already included in his count; he can, however, count them accurately if he is allowed to take each in succession into his hand. Similarly, though he often fails to count by vision alone fingers held at some distance apart in front of him, he succeeds if he is allowed to run his hand over them.

These and other tests indicate that not only do objects outside central vision fail to excite his attention

although he is not blind to them, but that he is also unable to orientate or localize in space the positions of objects seen in the peripheral parts of the retina, and the relative positions of those that come in succession into central vision.

This case consequently presents an apraxia of the oculo-motor movements similar to that described in the limbs, a defect in visual localization and orientation, and a failure of objects that stimulate the peripheral parts of the retinae to excite attention and the appropriate ocular movements.

Although his lower limbs are apraxic in imitating movements made in front of him, in attempting movements to order, and especially in more complex actions, as in putting on his trousers, he can now walk easily, but proceeds only in short, shuffling steps, as though not confident of himself. His gait is, however, not ataxic. If left alone, he quickly deviates from the direction in which he wishes to go and runs into objects even though he is aware they are present. When, for instance, he is asked to walk between two rows of beds, he frequently turns to the right or to the left and walks up against one; it is noteworthy that he more commonly deviates to the left, though the left halves of his visual fields are certainly unrestricted. Even when urged to keep his eyes to the ground and avoid obstacles, he often does not succeed; he has even run up against a wall or against a large screen which stands in the ward. He can, however, walk straight to a person or an object some distance away if urged to keep his eyes fixed on it, provided there are no obstacles in the way.

When he was brought into a large room in which a few chairs had been placed, and ordered to walk to a point which could be reached without encountering any serious obstacle, he almost invariably walked into a chair and then pulled up suddenly as if surprised at its presence, even though he had seen it and pointed to it before he started. After hesitating for a moment, as though uncertain how to get round it, he usually shuffled towards one side with side-steps, very much as a crab does when it meets a stone, frequently retraced his steps when almost around it, and after he had evaded it often set out in a wrong direction towards his goal. He explains his difficulty by saying, "I don't look where I am going and I can't always go where I want to," but if his movements are carefully observed it is obvious that it is chiefly due to the fact that visual impressions of the obstacles do not readily excite his attention.

An equally striking phenomenon^o is his inability, or at least his great difficulty, in finding his way about. When he is taken some distance from his bed he is unable to make his way to it again, even though he may see it and point correctly to it. On one occasion, for instance, he was brought about five yards from his bed, to reach which he had only to take a single right-angle turn, but though he indicated it correctly and recognized the patient in the adjoining bed, he turned to walk in a wrong direction when told to go to it. This happened even after the correct route had been pointed out to him. On another occasion, when taken into the next ward, he failed to return through the open door when asked to do so.

Although inattention to visual impressions certainly contributes to it, this inability to find his way about must be attributed chiefly to loss of spatial orientation and to inappreciation of direction and of the spatial relations of objects which he can see and recognize by vision.

SITE OF THE LESION.

The exact extent and position of the anatomical lesion which produced these symptoms is naturally of great interest. It may be assumed with considerable probability that the shrapnel ball had taken a direct course between its entrance and its exit, for in other cases of similar nature we found this to be the case.

Taking the points corresponding with entrance and exit wounds in this case, the brain was entered in the posterior and upper part of the right supramarginal gyrus, and we have reason to believe that the track passed through the dorsal part of this hemisphere, perforated the falx $1\frac{1}{2}$ cm. dorsal to and 1 cm. in the front of the posterior margin of the splenium of the corpus callosum, entered the left hemisphere in this position, passed just dorsal to

Wernicke's field in front of the knee of the optic radiations, and made its exit in the inferior part of the left supramarginal gyrus in front of the posterior end of the Sylvian fissure.

Experience has shown that the area of destruction and secondary change produced by such a missile is generally of considerable extent. The track would probably admit a finger.

Finally, it may be remarked that in several of the recorded cases of apraxia, and of disturbance of visual orientation and localization, the lesions corresponded more or less closely in position to that probably present in this patient.

MENTAL CONDITIONS FOLLOWING STRAIN AND NERVE SHOCK.*

BY

R. G. ROWS, M.D.,
TEMPORARY MAJOR, R.A.M.C.

THE following is a brief sketch of the work which is being done in the Red Cross Military Hospital, Maghull, in connexion with the mental and nervous disturbances occurring among those who have experienced the strains and shocks of a shorter or longer period at the seat of war.

The results produced on the nervous system by shocks of varying severity have frequently been described in detail, and it would be superfluous to collect again and classify the phenomena associated with a disturbance of the sensory and motor systems, of the vasomotor system, of the different organs of the body, and of all the functions of the mind.

Judging from the reports recently published in France—and these are fully corroborated by our own experience—it seems improbable that examination of the cases invalidated from the war will add very much to our knowledge of the symptomatology of these conditions. On the other hand, such an opportunity to investigate a large number of those suffering from psychic disturbances during the early stages of the illness has never been provided before. In this early period the patient is capable of co-operating effectively with the physician, and it is thereby rendered possible to go beyond the mere symptoms and to discover the psychic cause which has led to the determination of the form assumed by the disease and in many cases to trace the various stages through which the illness may have passed. This will perhaps be more easily appreciated if a series of cases is briefly described.

In the first place, the disturbances referred to above may appear in an intense form as the result of a shock, and, as in civil life, they will gradually disappear after a short period of rest and quiet in a hospital. But unfortunately the number of cases which recover so easily is limited. After several weeks or months in a hospital, and when most of the outward manifestations of shock may have disappeared, the patients will still complain of a changed feeling in themselves; there is produced an alteration in their personality which to them is something mysterious and for which they can find no satisfactory explanation. They confess to a slight loss of control and ask, "What is it that makes me so irritable at a little noise or at being brushed against by another patient as he passes me? I used not to be like that." As a result of this and of their inability to explain it to themselves, they suffer from a condition of anxiety, of apprehensiveness which is very troublesome and may form the starting-point for a more serious illness.

In some cases the physical expression of a special emotion, such as fear or terror, persists for a long time without much change. This condition is usually associated with an emotional state produced by the constant intrusion of the memory of some past incident. An example of this is seen in the case of a man who, after a charge, was placed on outpost duty. It was dark and he was in a state of considerable tension. He heard a noise,

* I have to thank the Medical Research Committee for the interest taken in the work of the hospital and for the assistance rendered in bearing the expense of circulating among the medical officers engaged on military cases of nerve shock a memorandum which has formed the basis of this paper.

which he thought came from some wire in front of him. Suddenly the area around him was illumined by a flare light and he saw a man crawling over the bank. Without challenging, he fired and killed the man. Next morning he found to his horror that he had killed a wounded Englishman who had advanced beyond his comrades and was crawling back. The physical expression of horror, together with an intense sweating and a very marked stammer, persisted for months. At the same time he was tormented with a fearful nightmare, and in his sleep he was heard to say, "It was an accidental shot, sir. Yes, Major, it was not my fault." In the daytime also his attention was concentrated on the memory of the incident, so that "I cannot forget it no matter how I skylark."

An examination back to this trying time which led to his recounting this terrible secret was followed by a marked improvement. The physical signs of the intense emotion gradually disappeared, the vividness of the dreams diminished, and his attention was less concentrated on the one subject. It is interesting to note that the production of a marked emotional state by the death of one of his children led to a recrudescence of all his symptoms—the expression of horror and the stammer—but they disappeared again in a short time.

In some instances the mental disturbance is complicated by the appearance of hallucinations relating to some experience at the front. These hallucinations and the dreams—both frequently occurring in the same patient—hinder the recovery of the patient, but rapid improvement almost invariably follows when an examination is made and the origin of the disorder is explained to him. It is found also that much may be done by educating the patient in a simple way to understand the mechanism of these morbid processes, so as to enable him to appreciate the importance of the emotional elements.

But the prolongation of the illness is not always due to dreams and memories of incidents connected with the war. Of equal, or perhaps of greater, importance in the longer cases are the memories of experiences in their earlier life with which a strong emotional tone was connected. These also may be revived in dreams, and in some instances they are added to the dreams of the incidents which occurred at the front.

In one case of this sort a man was tormented by the memory of an experience which happened to him during the first winter campaign. He and a comrade were carrying a pail of water to the trenches. It was very cold and they set down the pail in order to warm their hands. The comrade placed his hand against the cheek of the patient and said, "That hand is cold." At that moment he was shot dead. This incident was revived not only in dreams at night, but if during the day he were quiet and closed his eyes he could feel the cold hand against his face. He was much distressed by the frequent revival of this incident in such a realistic manner. But he was at the same time troubled by another dream, in which he ran down a narrow lane at the bottom of which there was a well. He dipped his hands into the water, but, on withdrawing them, he was horrified to find they were covered with blood. This dream was connected with a love affair in which his great friend interfered and angered him so much that he attacked him when next they met. He left him on the ground so injured that it was necessary to take him to a hospital. The patient became anxious as to what the result might be and left the district. He went to South Africa and later to America, but never heard whether the man he had attacked had died. The dream troubled him seriously and was difficult to unravel, but this and the one about the cold hand on his cheek disappeared after having been traced back to their origin. The patient made a rapid recovery, and has since been able to bear a severe trial satisfactorily.

The next case* referred to is an interesting example of the way in which, in a patient suffering from a disturbed mental condition following shock, the memory of a past incident led to an enormously exaggerated emotional value becoming attached to a recent occurrence. This patient broke out of hospital after having been refused permission to leave the grounds, and a statement regarding the offence was forwarded to the commanding officer of his

regiment. He became very depressed, said he would be disgraced, and that he would commit suicide rather than bring disgrace on his family. Investigation into this emotional outburst showed that his father had deserted the family, had got into prison and "tainted me." As he still remained in a very worried condition a further examination was made, and he confessed to feeling absent-minded and restless. For some time no explanation of this was forthcoming, but at a subsequent interview, after looking outside the door to see that no one was near, he said, "I want to tell you something, sir. Every night I wake to find that I have been restless and have thrown the clothes off the bed; also I find that I have 'lost nature.'" He was perpetually worried over this because he thought "the loss would affect my brain and would drive me mad." He admitted that he had gathered that idea from a book by Dr. X. which he had read years ago. It appeared also that Dr. X. had advertised a special bread and a special medicine which would preserve the nervous system, and that for years the patient had fed himself and his family with the bread and the medicine. But when it was pointed out that the book was written and the bread and the medicine were advertised by a charlatan with the view of making money out of those who were waiting to be duped, the restlessness at night and the "loss of nature" ceased.

The mental condition of this man has become practically normal, and a marked "tic" of the facial muscles and a general tremulousness have disappeared. It should be mentioned that in this case the dreams always began with some terrible experience in the trenches and then turned to some sexual acts with women, usually with his wife, and he awoke to find the clothes disturbed and also that he had "lost nature."

As an example† of hallucinations and delusions being dispelled by tracing them to their source and then giving the patient a clear insight into their nature, we may take a private, aged 31, admitted into this hospital suffering from hallucinations of hearing and delusions of supervision by his family and friends. He heard voices, apparently those of his brother, elder sister, and brother-in-law, telling him what to do and what not to do. The voices sometimes repeated his own thoughts and decisions. He had begun to form a theory about them, and considered that they belonged to a secret police entrusted with the task of supervising his actions and seeing that he did not again transgress as he had done.

An inquiry into his past revealed the following facts. He used to be a bank clerk, and as the result of drinking and smoking too much he had a nervous breakdown five years ago, and on the recommendation of his doctor he was given three months' holiday. While away he went with a prostitute. This was the first and only offence in sexual matters. At first he was not greatly disturbed by the memory of it, but when he went home some months later he thought he could detect a strangeness in the behaviour of his family, as if they knew of his misdeed. He then began to hear voices like those of his brothers and sisters proceeding from the wall, and, becoming rapidly worse and more depressed, he attempted suicide. After spending some months in a private asylum he emigrated to Canada, but was pursued by the voices and had to return to England. At the outbreak of the war he enlisted and went to France; but the voices distracted him so that he could not perform his military duties and he was invalided and sent to this hospital.

This patient during the five months of his residence in the hospital has been treated by the usual method employed here, namely, by seeking the cause of his mental disturbance. This was found in his affair with the prostitute and in his previous drinking. It was explained to him that the basis of his trouble was really the repetition of the memory of these incidents, together with the unpleasant emotional feeling associated with them, which had produced in him a self-reproach. When strongly under the influence of the self-reproach he had attempted suicide, and then the delusion of supervision had become grafted on and systematized. By persistent reasoning and persuasion week by week the process of systematization has been arrested and gradually the hallucinations and delusions have disappeared. The patient now has an insight

* I am indebted to Mr. T. H. Pear for permission to make use of this case.

† I have to thank Captain W. Brown, R.A.M.C., for permission to quote this case.

into the nature and origin of his illness and is to a large extent restored to health.

By means of this series of cases an attempt has been made not only to indicate the forms of mental disturbance observed among the patients admitted to this hospital, but also to show that the term "shock" by no means explains all the conditions of mental illness occurring in those who have returned from the front. Disturbances ranging from a slight, simple shock to a serious condition with hallucinations and delusions have to be observed. The more simple cases, which are popularly spoken of as "shock," recover quickly, but in the majority of instances there remains after the manifestations of shock have disappeared a "residuum," as Wernicke expressed it.

The work which is being done here is directed towards investigating the causes which have led to the persistence of this residuum and towards endeavouring by suitable treatment to assist the patients to recover. In order to understand the conditions we have to deal with it is necessary to consider the various factors which have been active in producing the disturbance. In the first place, it is important to remember that these men have lived through a prolonged period of strain before they have broken down under some special shock, such as the death of comrades at their side, the explosion of a shell near them, or the blowing up of a trench. Incidents such as these, together with the fatigue or exhaustion produced by life in the field, have led to the lowered capacity of resistance or control which is manifest in most of those who come under our care. Owing to their condition of lowered capacity the patients feel that they are not the men they were before the war began; they recognize a change in themselves and describe it clearly. They know that they are irritable, that they are unable to interest themselves or to give a maintained attention to a given subject. Instead of being jovial and social they are solitary and morose; instead of being good-tempered and taking things as they come they are irritable and find great difficulty in controlling themselves. All this is very real to them and leads to a condition of anxiety which is increased by their not being able to understand their condition; they worry because they fear how far this sort of thing may go. As a result they live in a state of expectancy which causes them to exaggerate the trifles of everyday life. Small incidents—slight psychic or physical disturbances which would have passed unheeded before the war—now assume a quite abnormal interest and importance for them.

All the conditions referred to so far can be observed in a merely superficial examination, but a deeper investigation will in many cases demonstrate that various other causes may have participated in producing the illness. These deeper causes—for example, the repeated revival of memories of horrible incidents at the front, terrifying dreams, and also memories of incidents of their past lives—have played a large part in determining and maintaining the disturbed mental condition. Examples of the action of these causes have been given in this paper, and it is perfectly evident that the incidents which have had such a disturbing influence have been those with which an intense emotional state has been associated. Dejerine has suggested that in all cases of hysteria and neurasthenia the cause must be sought in some antecedent emotional condition. The results of the investigations among these patients demonstrate that this principle is capable of a much wider application.

It is the strong emotional factor which so compels the attention of the patient. The normal freedom of their mental activity is interfered with, and in some instances the attention is so fixed on the disturbing influences that the offending memories and their accompanying emotional states cannot be expelled. Then may follow the appearance of hallucinations and the development of delusions which the patient employs to explain his condition to himself, and the repeated dwelling on these delusions leads to a habit of mind which becomes more fixed as time goes on unless some active and suitable treatment is adopted.

While in this state the patient is to a large extent incapable of reasoning about his condition; he is unable to make use of the sum total of his past experiences; he gives way to the emotional states in which he may find himself, or he dwells on the explanation he may have accepted. His difficulty lies chiefly in the fact that he has

little or no insight into the nature and mode of origin of his mental illness. This insight can be provided by explaining to him in plain language the mechanism of simple mental processes, by enabling him to understand that every incident is accompanied by its own special emotional state and that this emotional state can be reawakened by the revival of the incident in memory. The patient will thus be led to see that it has been no gross disease and no supernatural agency which has disturbed him; he will be able to recognize the relation of cause and effect in the origin and development of his illness.

When this relation is appreciated both the patient and the physician will begin to realize that they have some ground in common. And this stage being reached, the mystery of the illness will be swept away and the physician will be able to explain to some extent the reason and the mechanism of his loss of control, of his disturbed attention and of his lack of interest, and also to show him how he can educate himself to regain that which was lost. The patient will understand that it will not be possible for him to banish the memory completely. But he can be induced to face the trouble, to reason about it, and to recognize it simply as a memory of the past instead of allowing the emotional tone connected with it to dominate him until the condition of anxiety had been produced. The excessive emotional tone will thus be stripped away and the patient will become able to appreciate the real value of the incident, and this will assist him to recover from the condition of confusion, disturbed attention, and anxiety, which, if neglected, may lead to serious results. Further, just as in each case the disturbance can be traced to a specific incident or series of incidents, so the re-education must vary with each in order to overcome the difficulties connected with the specific cause which has been discovered.

The difficulties in the processes of investigation and treatment of these cases are often considerable, and it must be recognized that recovery will not take place in every instance. But the results obtained demonstrate that many mental illnesses recover in a most satisfactory manner under a well-directed and sympathetic treatment. The confidence of the patient must be obtained in order that he may be induced to co-operate in the treatment of his illness. This co-operation is indispensable, and it is extremely interesting to find how readily it can be obtained from patients in whom the illness has lasted only a short time. And when the difficulties, often insurmountable, which are encountered among those in whom the mental disorder has become fixed and systematized are considered, the value of the early treatment of mental disturbances in a hospital by an efficient staff who devote their whole time to the work, at once becomes manifest. The physician should be prepared to give at least an hour for an interview and in most instances several interviews will be necessary. Short cuts may be attempted; they rarely lead to success. A prolonged study of each separate case will not only provide a means of treatment for the individual, but will also collect a mass of evidence which will help to develop a new and enlarged view of psychological medicine.

MENTAL SYMPTOMS COMPLICATING A CASE OF ACUTE TETANUS DURING TREATMENT BY CARBOLIC INJECTIONS.

BY

JOHN EVERIDGE, F.R.C.S.ENG., CAPTAIN R.A.M.C.T.,

TEMPORARY ASSISTANT SURGEON, KING'S COLLEGE HOSPITAL;
SURGEON TO THE NEW ZEALAND MILITARY HOSPITAL, ETC.

THANKS to the valuable prophylactic effect obtained by prompt injections of specific antitoxin, cases of tetanus occurring among the wounded in the present war are quite infrequent. Consequently I offer no apology for publishing notes of the following case:

On November 11th, 1915, while unloading an ammunition wagon on the lines of communication, Gunner C. was struck by fragments of a high-explosive shell, which exploded close to him. He was severely and extensively wounded in the right buttock, right thigh, and right foot, as well as in the left leg. The wound of the right foot was very severe, the fragment of

shell having torn most of the extensor tendons and laid open the ankle-joint.

Earlier in the war it was the custom to make careful inquiries as to whether or not a wounded patient had received a prophylactic injection of antitetanic serum. The administration of these injections has become so much the invariable practice at the front that in the base hospitals one has ceased to ask the question.

Thus it happened that it was not until the occurrence in this case of subsequent events that one was led to investigate the question. The patient did not remember having received an injection; but it is possible that it was given while under an anaesthetic at the time of his first operation in France, or, on the other hand, it may have been that, wounded as he was far behind the firing line, he missed receiving treatment at a field ambulance or at a clearing station.

He came under my care at the 4th London General Hospital on November 16th, 1915, five days after he was wounded. For some days the wounds, which were extremely septic, were treated by peroxide irrigation and boric fomentations.

Six days later—on November 22nd—some trismus and a definite risus sardonicus were noted. He was at once given 4,000 U.S.A. units of antitetanic serum, and 1 c.cm. of 1 in 20 carbolic acid was injected subcutaneously every four hours. He received a further 1,500 units of serum the same evening.

Had it been possible to localize the focus of infection as being in the wound of the foot, it would have been an easy matter to amputate immediately, especially as the foot was so severely injured that the prognosis was not hopeful. But in the presence of other septic wounds, any one of which might be equally the source of infection, it seemed to me wiser to secure efficient drainage everywhere by means of opening and irrigating thoroughly the wounds of the thigh and buttocks, and by an astragalectomy on the foot.

After the initial symptoms the march of events was rapid. The muscles of the abdomen and back were strongly contracted, and convulsions occurred frequently. On the evening of November 23rd he was given 1,500 units, as well as a quarter of a grain of morphine and 2 drachms of chloral. The pain in the back and leg was severe. On November 24th he had a further 1,500 units of serum, chloral, and bromide every six hours and morphine in the evening. The same course of treatment was pursued on November 25th. On November 26th and 27th the patient remained in a semi-comatose state from the effects of the chloral and bromide. Whenever he was allowed to come round at all the spasms became intense; on November 28th they were less severe, and on November 30th he was treated less energetically with hypnotics. The mental condition now began to show a marked change. He became extremely restless and passed into a state of low, muttering delirium, with visions and hallucinations—a condition closely resembling delirium tremens. From time to time he attempted to get out of bed, and had to be forcibly restrained. This lasted for five days, during which time he had incontinence of urine and faeces. Chloral and bromide, which had previously quieted him, had now no effect. After four four-hourly doses of half a drachm of paraldehyde, however, he settled down into a quiet sleep.

On December 7th incontinence had ceased and he had regained a more normal mental state. Paraldehyde was continued every four hours until December 8th, as well as occasional injections of morphine and atropine and draughts of chloral. On December 9th the mental condition appeared normal, but on December 10th there was a bad relapse with more incontinence. This lasted acutely for three days, but it was not until December 20th that the mental state again became normal and he was able to recognize those around him.

With the exception of the single shell explosion noted above, the man had never been under fire. This fact, as well as the delay in onset of the mental symptoms, tends to show that they were not due to shell shock. On the other hand, I am not familiar with the occurrence of such a form of delirium as being a symptom of tetanus itself. This is also the experience of those of my colleagues with whom I have consulted. I have thought it possible that the carbolic acid injections may be not unassociated with the condition.

Injections of 1 c.cm. of 1 in 20 carbolic acid were given at four-hourly intervals from November 22nd till December 4th. At no time, however, were there any other symptoms of carbolic acid poisoning.

The patient's general health is now (February) perfect, and there is no trace of mental instability. The movements at the ankle are quite good, and with his remaining extensors he is able to carry out a fair degree of dorsiflexion.

THE Secretary of the United States Treasury, Mr. W. G. McAdoo, has transmitted to the House of Representatives, on behalf of the Public Health Service, a recommendation for an emergency appropriation of £20,000 for the promotion of rural sanitation with the object of checking the spread of pellagra and typhoid fever.

A CASE OF ACUTE GANGRENOUS CHOLECYSTITIS WITH SPREADING PERITONITIS OCCURRING IN THE EPIDEMIC OF JAUNDICE, GALLIPOLI, 1915.

BY
